AUTHORS' PREFACE.

THIS Dispensatory is designed to succeed the *National Dispensatory* of Stillé and Maisch, which for so many years has held its place as a standard work of reference with the professions of medicine and pharmacy. It contains not only every article in the new United States Pharmacopœia with comments and explanations, but it covers as well the additional and very extensive territory of the unofficial drugs and preparations largely in use, and so offers to its readers information concerning all substances used in pharmacy and medicine at the present day.

The rapid advances in the various sciences closely connected with its scope, and the appearance of the new United States Pharmacopœia, with its radical changes in many important matters, have necessitated a careful and adequate consideration of many new subjects.

In the department of Pharmacognosy the Author has covered the minor drugs as well as those of greater importance, in their due perspective. This constitutes a new departure of value to those who wish information concerning remedies which have only a local reputation, and about which little is to be found in ordinary literature. In the discussion of additional species, advantage has been taken of the opportunity to refer to the principal economic members of the groups, so that the book is a fair index to the economic botany of all the more important families of medicinal plants. A sufficient amount of information has been given for the practical identification of drugs rather than full technical descriptions. This is especially true in regard to powdered drugs. Botanical descriptions of drug-yielding plants have been introduced only in the cases of those likely to be met with by the general reader, or when the information is desirable for some special reason, as, for instance, in regard to plants capable of causing poisoning. The illustrations of typical specimens of drugs mostly executed by the skilful botanical artist, Mrs. Beutenmüller, have been drawn so as to represent as nearly as possible their appearance as they occur in commerce. In order that the reader may find any name encountered in the descriptions of vegetable drugs, the greatest fulness in nomenclature has been resorted to. Nearly all recorded common names of drugs or medicinal plants have been given, and in addition all botanical synonyms, the oldest names, both generic and specific being preferred, since this has now become the guiding principle in botanical nomenclature.

In the pharmaceutical sections full information will be found regarding methods and products, with descriptions and explanations of the most approved apparatus and tests. This material is particularly useful to the druggist, because the Pharmacopœia is of necessity devoid of explanatory notes. In addition to this

information all important facts contained in the new editions of the chief foreign Pharmacopœias have been introduced. It has been the endeavor of the authors to supply in every article the latest information. The subjects of alkaloids and fixed and volatile oils have been considered with especial fulness, and much additional matter relative to new synthetic and other remedies will be found.

The Pharmaceutical Author has received valuable assistance on special lines from gentlemen whose names carry the greatest weight of authority. The articles on Inorganic Chemicals have been prepared by Daniel Base, Ph.D., Professor of Inorganic and Analytical Chemistry in the University of Maryland. The section on Volatile Oils and their Constituents is from the pen of Edward Kremers, Ph.D., Professor of Chemistry in the University of Wisconsin, a recognized authority and specialist in everything pertaining to this interesting and important class of plant products. Much valuable assistance in the sections on Organic Chemicals has been rendered by Joseph F. Geisler, Ph.C., Chemist of the New York State Department of Agriculture, whose great experience in the handling of commercial and other products has enabled him to contribute a large amount of useful information.

In the sections on Action and Uses the Medical Author has endeavored to give a direct and compact presentation of modern therapeutics, avoiding historical and theoretical matter. The information given in connection with the various drugs is placed at immediate command for clinical purposes by means of the extensive *Therapeutical Index*, in which, under the name of each disease, will be found references to all the medicines employed in its treatment, and in the article relating to each medicine the condition calling for its employment. The usefulness of such a repertory of therapeutics to the physician in his daily practice scarcely needs to be pointed out. The author of these sections desires to thank a number of gentlemen who have given him valuable assistance in the preparation of the portion of the book under his charge: Dr. E. M. Houghton, pharmacologist to Parke, Davis & Company, who has written the articles on Physiological Assaying, Vaccine and the various Sera; Dr. E. Russell Kennedy, and Dr. Alfred Heineberg, Demonstrator of Pharmacy in the Jefferson Medical College.

The effort to cover a field so immense, even within a volume of generous size, has rendered the problem of selection the most difficult of all which the Authors have had to solve. They have been guided by the principle of introducing information which will prove of practical value and interest to active practitioners of pharmacy and medicine.

PUBLISHERS' NOTE.

THE two professions especially interested in the subjects of this volume are fortunate in having at command the work of authorities whose eminence in their respective fields is recognized throughout the world. Professor Rusby contributes the sections on Pharmacognosy, Professor Caspari those on Pharmacy, and Dr. Hare those on Medical Action and Uses. The authors have furthermore had the assistance of experts in certain important special subjects. For their part, the Publishers may claim that an experience of twenty-five years, spanned by five editions of *The National Dispensatory*, has prepared them to appreciate the many requirements to be expected in such a work, perhaps the most elaborate and certainly one of the most useful in all medical literature. Together, the Authors and Publishers have spared no effort to mark a new departure with *The National Standard Dispensatory*. The new features are briefly indicated in the foregoing Preface.

The sweeping changes in the new *United States Pharmacopœia* are included with the official authorization of the Committee of Revision, and full use has been made of valuable information appearing in the latest issues of the chief foreign pharmacopœias. This Dispensatory, however, covers a much wider field, as it includes not only all official drugs, but also those which are unofficial and well established. The aim has been to make it a repertory of the highest authority upon the entire range of Materia Medica, Pharmacy and Therapeutics in their latest development.

Throughout the text all weights and measures are given in both the metric and ordinary systems, and many new tables and lists have been inserted which place before the reader a vast amount of information in a form combining compactness with ease of reference in the greatest degree. The text is supplemented with an Appendix which will be highly convenient for practical purposes. It contains a list of Reagents and Tests; Directions for Volumetric Assays; Official Acids and Alkalies; Formulas and Molecular Weights of the Principal Chemicals; Weights, Measures and Equivalents; Thermometric Equivalents, and an Alphabetical List of Drugs, showing the preparations of the United States and British Pharmacopœias containing them. The extensive *General Index* and the *Index of Therapeutics* close the volume. Ample illustrations have been introduced, a very large proportion being new and original.

THE NATIONAL
STANDARD DISPENSATORY.

A.

ABRUS.

Arbre a Chapelets Fr.; *Abrus precatorius* L. (*A. pauciflorus* Desv., *A. squamulosus* E. Mey.—Fam. *Leguminosæ*).

The root, leaves, and seeds are of interest in materia medica, and have been examined. The plant is a nearly smooth, slender woody vine, climbing high upon trees and shrubbery in nearly all tropical countries, preferring a sandy soil and sunny positions in the edges of forests. It bears small rose-colored flowers, and fruits resembling very small pea-pods, containing about 4 to 6 seeds. Its historical interest is chiefly toxicological; its modern, chiefly ophthalmological.

Abrus Root (*Indian liquorice, Jamaica wild liquorice*).—Much-branched, tortuous, woody, hard, brittle, about 0.6 Cm. (¼ In.) thick, reddish-brown externally and through the bark fracture, yellowish-white through the wood fracture, bearing almost no resemblance to liquorice. Bark very thin, slightly sweet, acrid.

This root was recognized in the Indian Pharmacopœia under the mistaken notion that it could substitute liquorice. The result was quite unsatisfactory. It is recognized in India as being emetic, abortifacient, and poisonous in the same way as, but very much weaker than the seeds, and as containing the same or very similar compounds. Hooper found it to contain 8 per cent. of an acrid resin and 1.5 per cent. of glycyrrhizin.

Abrus Leaves.—Abruptly pinnate and possessing 10 to 20 pairs of nearly sessile, narrowly oval-elliptical leaflets, about 1.2 Cm. (½ In.) long, almost smooth, except the short petiole, entire, thin, pale-green, inodorous, distinctly sweet, slightly acrid.

The leaves have not been used, but Hooper has pointed out that, as they are the sweetest part of the plant, they, if anything, might be used as a liquorice substitute. His examination showed them to contain about 10 per cent. of glycyrrhizin ("glycyrrhizic acid"). He believed part of this to exist free, while the remainder might have been combined with potassium and calcium.

Abrus Seeds (*Jequirity, Chicken-eyes, Crab's-eyes, Prayer-beads, Jumble-beads, Love-peas, Retti, Gunj, Gunjha*, etc.).—Nearly globular, slightly elongated, about 0.6 Cm. (¼ In.) long, hard, smooth and brightly shining, scarlet with a large black patch around the hilum near one end, rarely white with a black patch or black with a white patch. The testa is rather thick and hard. The kernel consists, as in the bean, of two plano-convex cotyledons.

Fig. 1.

Abrus seed (× 2).

These seeds are employed largely for the making of rosaries and for other ornamental purposes. That they are dangerous playthings for children is attested by the records of a number of cases of poisoning which have occurred in this way. They have also been used in India from very ancient times for the purpose of weighing gold. Their medicinal importance is not great, but they have a notorious history in India as an agent in criminal poisoning. This practice has been directed chiefly against cattle and other live stock, but the poisoning of human beings has been not infrequent. Poisoning may result from the taking of the seeds internally, though not in the same small doses which will produce it when introduced directly into the circulation. Forty seeds have been ingested, with serious results, but

there was final recovery. The ordinary method of application for poisoning is by grinding the seeds to a very fine pulp with water, moulding the mass into a small sharp point like the end of a pencil, and affixing it to the end of a stick. This point is used to prick the skin of the intended victim, with a promptly fatal result. Two or three such prickings through the skin of an ox will, it is said, result in the death of the animal before the next morning. Such a hardened point is known by the name of *sui* or *sutari*. Instead of water, a vegetable milk-juice sometimes is employed for mixing.

The poisonous constituent of Abrus seeds long was known by the name of *abrin*, but later this was found to be a compound substance, consisting of a globulin and an albumose, both of them extremely poisonous. A temperature of from 75° to 80° C. (167° to 176° F.) at once destroys the globulin, while 85° C. (185° F.) is required to destroy the albumose. Any temperature above 50° C. (122° F.) weakens the action. The method employed by Hooper for the separation of the globulin was to extract it with a 15 per cent. solution of sodium chloride, acidulating with acetic acid, and precipitating by saturation with sodium chloride. This precipitate, containing some albumose, was mixed with distilled water and dialyzed in running water for several days, the globulin being precipitated, while the albumose remained in solution. The albumose was prepared by extraction with water and precipitation by filtering into absolute alcohol. The precipitate was redissolved in water and reprecipitated by alcohol at intervals. At the end of about eight months the globulin had coagulated completely, and the albumose was still soluble. The general composition of jequirity is similar to that of other leguminous seeds.

Action and Uses.—Abrus has been used by de Wecker and others in the form of an 0.5 per cent. infusion in the treatment of pannus, granular ophthalmia, and trachoma, but it has never met with favor in this country on account of the violent symptoms resulting from its use.

Applied to mucous membranes, the drug acts as an intense irritant, and if frequent applications are made causes violent inflammation and suppuration. Applications to the conjunctiva produce œdema, swelling, and some serous discharge. Later the discharge becomes purulent, and there may be suppuration of the parotid and submaxillary glands as well. If used in too concentrated a form, it may cause corneal ulcers, or even produce panophthalmitis. The lower eyelids occasionally become gangrenous.

Introduced hypodermically into the subcutaneous tissues, it produces gangrenous ulcers, and when injected into the circulation it is a powerful cardiac depressant poison.

Solutions of the drug undergo rapid decomposition, and should either be made freshly each time they are used or be preserved by the addition of 4 to 8 grains (0.25–0.50 Gm.) of boric acid to the ounce.

If an excessive action of the drug is developed, it may be controlled by compresses moistened with hot and very dilute solutions of corrosive sublimate.

Allied Drug.—Cassia Absus L. has oval-oblong, flat, glossy-black seeds, which are used in Eastern countries in purulent conjunctivitis and as an application to sores. Used in the same way, in India, are *C. auriculata* L. (*Tarwar, Ranavara,* in China called *Kineh-mang*) and *C. Tagera.*

ABSINTHIUM.—Wormwood.

Maderwort, Mingwort, E.; *Wermuth, Warmot, Wurmtod,* G.; *Absinthe grande, Alsei, Aluyne,* Fr.; *Ajenjo,* Sp.; *Absinthis, Acintro, Losna,* Port.; *Assenzio,* It.

The dried leaves and tops of *Artemisia Absinthium* L. (*Absinthium officinale* Brot.—Fam. *Compositæ*).

Absinthium is official in most pharmacopœias, but not in the United States and British. The Dutch requires collection at the beginning of flowering and uses only the flowering tops. The Portuguese allows alternative use of the leaves of *Artemisia arborescens* L. ("Losna de Algarve"). The definition would be improved by saying "the flowering tops," etc., as the drug is then more active. The fresh herb is three or four times heavier, therefore weaker, than the dry.

Absinthium is a native of Europe, Northern Africa, and Asia, and is naturalized in most temperate and subtropical countries, being rather scarce in the United States. It is cultivated largely in Europe and in several parts of the United States for the manufacture of its oil. Under cultivation, its taste becomes milder and its aroma finer. In Europe it is used to a considerable extent for imparting a bitter taste to beer and for

ONTARIO
COLLEGE OF PHARMACY
44 GERRARD ST. E.
TORONTO

the preparation of the French absinthe, a liqueur which is found to be much more injurious to the nervous system than plain alcoholic liquors. The poisonous properties of this drink have clearly been shown to be due to the oil of absinthium present, notwithstanding that this conclusion has been disputed. With this oil, those of anise, coriander, fennel, mint, hyssop, angelica, and melissa are associated usually in absinthe.

Description (see Fig. 2, A and G).—Soft-shrubby, finely silky-hairy and glandular throughout, erect-branched; lowest leaves long-petioled, up to 12 Cm. (5 In.) long, roundish-triangular, thrice pinnately divided or lobed, the segments oblong to obovate, obtusish, toothed, or entire; upper leaves becoming gradually shorter-petioled, smaller, narrower, and less divided, the uppermost 2.5 Cm. (1 In.) long, sessile, oblanceolate or linear-oblong, entire; heads numerous, racemose-paniculate, on drooping peduncles, greenish-yellow, about 4 Mm. ($\frac{1}{8}$ In.) broad, globose-ovoid, the outer bracts linear-oblanceolate, obtuse, the inner becoming broader and with scarious margins, the receptacle hairy; flowers all fertile or the outermost sterile; aromatic and persistently bitter. (See also generic description below.) The radical leaves are rarely present, sometimes 19 Cm. (8 In.) long and broad.

Constituents.—The important constituents are volatile oil and bitter principles, associated with starch, a little tannin, succinic ("absinthic") acid, partly free and partly combined with potassium, and about 7 per cent. of ash.

Oil of absinthium (*Oleum absinthii*) is in variable amount, being obtainable to the extent of upward of 1 per cent. from the dry plant. It is brown, becoming green or occasionally blue on exposure, specific gravity 0.925 to 0.955, slightly viscid, very bitter and disagreeable, the taste closely resembling that of the drug, and is soluble in alcohol. Its principal constituent is *thuyone* ($C_{10}H_{16}O$, the same as *absinthol* or *tanacetone*). With this is thujyl alcohol ($C_{10}H_{18}O$), partly free and partly apparently combined with acetic, isovalerianic, and palmitic acids; phellandrene, and possibly pinene; cadinene; also a bluish oil which has not been determined (Gildemeister and Hoffmann). This oil is apt to be adulterated with oil of turpentine.

The bitter principles are the oil above described, the resin (probably because it contains the next), and *absinthiin* ($C_{15}H_{20}O_4$). Absinthiin is a glucoside, yielding a volatile oil. It crystallizes in white prisms, is soluble in alcohol, water, and ether, and is precipitated by tannin.

Pharmaceutical Preparations.—EXTRACTUM ABSINTHII.—*Extract of wormwood*, E.; *Wermutextrakt*, G.—It is prepared according to the German Pharmacopœia with a menstruum composed of 91 per cent. alcohol, 1 part, and water, 4 parts. The French Codex directs extraction with boiling distilled water.

TINCTURA ABSINTHII.—*Tincture of wormwood*, E.: *Wermuttinktur*, G.—The German Pharmacopœia directs maceration of 1 part of wormwood, finely cut, with 5 parts of 68 per cent. alcohol for 7 days. The mixture is then expressed and filtered.

Action and Uses.—Absinthium is sometimes used in household medicine. It acts as a tonic in small doses, and has been widely employed in atonic conditions of the digestive and genital tract. At one time it met with some favor as an anthelmintic. In overdoses it acts as a narcotic poison, affecting principally the central nervous system, producing headache, tremors, hallucinations, and epileptiform convulsions. It is an excitant to the circulation and an irritant to mucous membranes.

The drug is usually administered in the form of an infusion made with 1 oz. (30 Gm.) of wormwood in 1 pint (480 Cc.) of water. The dose is from 1 to 2 fluidounces (30 to 60 Cc.).

Other Species.—The genus *Artemisia* L. contains more than 200 species, well distributed through the northern hemisphere, with a number in South America. No less than 60 species have been named by Dragendorff as in medicinal use. Since most of these agree in their general medicinal properties, the recognition of the genus is a matter of some importance, so that its botanical characteristics are here given.

ARTEMISIA L.—Fragrant, alternate-leaved, usually hairy herbs or under-shrubs. the small heads usually pendulous, their involucres ovoid or broadly bell-shaped, the scales imbricated in few series, the outer successively shorter, their margins scarious; receptacle plane to hemispherical, naked or hairy; outer circle of yellow or yellowish-white florets pistillate, fertile, the corollas slenderly tubular (rarely wanting), the others perfect, fertile or sterile, their corollas broadened above; anthers obtuse and entire at the base, appendaged at the apex. Akenes various.

Several of the species are used so extensively as to require special mention. *A. maritima* will be considered under Santoninum; *A. Dracunculus* L. (Fig. 2, E), under Oil of Estragon. The volatile oils of *A. Gallica* Willd., *A. Barrelieri* Bess., and *A. glacialis* L. are more or less known.

A. VULGARIS L., the *Mugwort* (*Muggert* or *Mugweed*), *Sailors' tobacco*, *Felon herb*, *Bulwand*, also called incorrectly *Wormwood* (Fig. 2, C), has very widely been introduced to the United States from Europe and Asia. It is distinguished readily from the other species by its broad leaves and leaf-divisions, the upper surface bright green, drying brownish, the inferior silvery white. It is very inferior to wormwood, and is used as a bitter tonic in much larger doses. The fresh herb contains about 0.2 per cent. of an unimportant oil, said to contain cineol and having a specific gravity of 0.907.

A. FRIGIDA Willd. (*Wild sage*, *Mountain sage* or *Sierra salvia*) (Fig. 2, D, densely silky-canescent), is one of the most highly prized drugs of the miners and frontiersmen of the Rocky Mountain region in the treatment of their "mountain-fevers."

FIG. 2.

A, *Artemisia Absinthium*, stem and flower-branch; B, *A. Mexicana*; C, *A. vulgaris*; D, *A. frigida*; E, *A. Dracunculus*; F, *A. Ludoviciana*; G, hair from leaf of A; H, *A. Abrotanum*. All reduced one-half, except G, which is enlarged.

A. ABROTANUM L. (*Southern wood*, *Old man*, *Lad's love*, *Maid's love*, *Slovenwood*, *Smelling-wood*, *Sweet Benjamin*, *Stabwurzel*, *Aurone male*, *Citronelle*, *Abrotano*) (Fig. H, smooth or slightly pubescent), is a native of Southern Europe and adjacent Asia, largely cultivated both as an ornamental and a medicinal plant, and is lemon-scented.

A. MEXICANA (Fig. 2, B) is used largely in Mexico as the mountain sage is in the northwestern United States.

A. TRIDENTATA Nutt., or *Sage bush*, is a large species of the western United States, used similarly to the mountain sage.

Similarly used are *A. Ludoviciana* Nutt. (Fig. 2, F, white-woolly), the *Western mugwort* of the northwestern United States, *A. Dracunculoides* Pursh. of the western United States, and *A. Pontica* L., the *Roman wormwood*, native of Europe and Asia, very largely employed as an inferior substitute for absinthium.

ACACIA, *U. S.*—Gum Arabic; Gum Senegal.

Galam gum, *Gummi acaciæ*, *Gummi Africanum*, *Gummi Arabicum*, *Gummi Mimosæ*; *Gomme Arabique Vraie*, Fr.; *Goma Arabigo*, Sp.; *Gomma del Cordofan*, It.; *Gomma Arabica*, It., Port.

The dried gummy exudation from *Acacia Senegal* Willd., or from other species of *Acacia* (Fam. *Leguminosæ*).

Acacia is official in all pharmacopœias. Other species named by them as yielding the gum are *A. Arabica* Willd., *A. tortilis* Hayne, *A. vera* Willd., *A. Verek* Guill. et Per., *A. Seyal* Del., *Mimosa (Acacia) Nilotica* L., "and other species."

The term "gum Senegal" is not, strictly speaking, synonymous with "acacia," although it is commonly so used. Acacia is the name originally pertaining to Soudan, Kordofan, or Egyptian (*hashabi*) gum, which possesses properties rendering it superior and always preferred to any other known to commerce. During the political and military disturbances in Egypt between 1880 and 1890, this gum became so nearly unobtainable that occasional packages only were seen in market, their appearance being regarded as in the nature of a curiosity. Among the many substitutes then offered, the best was gum Senegal (*Varek*), which therefore was adopted as the official equivalent of acacia. In this way it naturally came about that the names were regarded as synonymous. In 1890, the original acacia again came into the market, and eventually became as abundant as ever, but it is no longer easy to separate entirely the two names.

Description.—In roundish tears of various sizes, or broken into angular fragments, with a glass-like, sometimes iridescent fracture, often opaque from numerous fissures, but transparent and nearly colorless in thin pieces; nearly inodorous; taste insipid, mucilaginous; insoluble in alcohol, but soluble in water, forming a thick, mucilaginous liquid.

Acacia should be slowly but completely soluble in 2 parts of water. This solution shows an acid reaction with litmus-paper, yields a gelatinous precipitate with basic lead acetate test-solution, ferric chloride test-solution, or concentrated solution of sodium borate, and does not reduce alkaline cupric tartrate volumetric solution.

The powder is not colored blue (absence of *starch*) or red (absence of *dextrin*) by iodine test-solution. It should yield not more than 4 per cent. of ash.

Neutral lead acetate does not precipitate it, nor does tannin. Acacia loses about 15 per cent. of moisture at 100° C. (212° F.). The British Pharmacopœia limits the ash to 4 per cent., the Swiss to 5 per cent.

The U. S. P. description was not modified in 1890 to accommodate it to the Senegal gum, then mostly in use. The description, "opaque from numerous fissures," rarely is realized by the latter, which is tougher, more glassy, rarely so white, and more slowly soluble. It occurs much less frequently in the small angular fragments so characteristic of acacia proper.

Most works, American and foreign, teach that both the Kordofan and Senegal gums are products of *Acacia Senegal* Willd., the range of which is thus given as Senegambia, in western Africa, the upper Nile region, in eastern Africa, with more or less of the intervening central region. Upon this view is based the statement that the two gums represent merely different grades of the same product. While the marked and constant difference between them renders this view extremely unlikely, the fact is of little importance from a practical point of view. It would be well, however, for the official definition to state "or from other species of acacia," depending rather upon the description than the definition to fix the limits of exclusion. *A. glaucophylla* Steud. and *A. Abyssinica* Hochst. are said to yield an equally good gum, but little of it is believed to reach the market. Some authors have named other species as yielding the Senegal article, but their reports are apparently too careless for dependence. Even if the gums are yielded by two species, the latter must be very similar, since all the gum-yielding acacias exhibit the same habit and general appearance, differing only in technical characters. They are spiny shrubs or small trees, with bipinnate leaves, preferring sandy or sterile regions, with the climate dry during a large part of the year.

Acacia, like other gums of its class, forms within the cells of the cortex and adjacent parenchyma, the process beginning in the cambium, by little understood processes, collectively named by the term "gummosis." It appears most likely that the gum is to be regarded merely as a waste product, though various other theories have been proposed. Lutz states that the first noticeable change is that of an alkaline to an acid reaction in the cell-wall, upon the inner surface of which the gum collects. The wall then becomes greatly thickened, with a corresponding diminution in the size of the cavity. Finally, the parenchymatic tissue degenerates into a gummy mass. It is believed generally that an unhealthy or poorly nourished condition favors gum-production. At certain seasons of the year, and only in certain years, at long intervals, the gum exudes through perforations, even very minute ones, accidentally occurring, or sometimes made by the collectors (especially for obtaining Gum Senegal). It is claimed that along the Senegal River the exudation is commonly through openings primarily caused by the germination

of the parasitic plant *Loranthus*. The gum usually forms upon the surface in the form of irregularly rounded masses called "tears," but sometimes in vermicular forms. It may be collected while adhering to the bark or after it falls to the ground. The entire product, often of various species, thus collected, is mixed and carried to the centres of accumulation, and then to the points of export, chiefly, for the Kordofan article, Cairo, Alexandria, and Trieste. It is then known as "acacia sorts" or "acacia in sorts," the term being thus equivalent to "unassorted acacia." In our market, this term is not used in exactly this sense, but refers more commonly to those portions of the former article which are so inferior in quality as to be deemed unworthy of farther assorting, or in the nature of refuse. The unsorted gum shows the widest variation as to size of fragments, whiteness, clearness, or transparency, and freedom from adhering foreign matter. It next is assorted or "picked" in accordance with these differences. The different lots are known then as "first picked," "second picked," and so on, down to the "sorts." Thirty-two grades are said to be recognized at Trieste. The "first picked" and "second picked" are very similar indeed, being indistinguishable to most persons unless the two are seen together, and much of the latter is sold for the former. It is a shade less white and less crackled or fissured, but is perfectly clean, free from impurities, and available for all uses except where the most perfect freedom from color is desired. The lower grades are manifestly unfit for pharmaceutical uses, and are employed chiefly and very extensively in the arts.

Composition.—Acacia consists principally of a compound of arabic acid with calcium, varying amounts of the magnesium and potassium salts of the same acid being present. It is believed also that small amounts of other salts of these bases occur.

ARABIC ACID ($C_{12}H_{22}O_{11}$) can be obtained by precipitating with alcohol from a solution of acacia acidulated with hydrochloric acid. It is then soluble in water, but becomes insoluble on drying. It is not crystallizable. *Galactose* and *arabinose* are yielded upon boiling it with dilute mineral acids. It is possible to convert a portion of acacia into sugar by repeated boiling with dilute sulphuric acid.

Adulteration.—Adulteration in the crude condition is confined almost wholly to the addition of similar and inferior gums, the detection of which requires only familiarity with the genuine article. In the ground condition, it is adulterated oftenest with starch and dextrin, tests for which are given in the official description. When inferior gums are ground with it, they are detected most commonly by the darkened color. Otherwise the tests for solubility and viscosity must be applied.

Action and Uses.—Acacia possesses little medicinal action. Locally applied, it is soothing to irritated or inflamed mucous membranes, especially of the upper air-passages. It has also been recommended in similar conditions of the gastro-intestinal and genito-urinary tracts. Its principal use, however, is as a vehicle for more powerful remedies.

Acacia is usually administered in the form of a mucilage (*Mucilago acaciæ*) in doses varying from 1 to 8 drachms (4–30 Cc.).

Other Gums.—Gums are divided commonly into those based respectively upon compounds of arabic, bassoric, and cerasic acids. Of the last class, none is of commercial or pharmaceutical interest. Those of the second class will be considered under Tragacantha. Of the first class, a large number are, have been, or may become of commercial importance. Their value depends upon the following properties, positive or negative: absence of impurities; insipidity; absence of color (or possibly special coloration for special uses); solubility; viscosity (often spoken of as the "stockiness" or "body"); permanency, or absence of tendency to sour or change color. In testing gums, or in considering their availability as substitutes for acacia, it is the above-mentioned characteristics which have to be measured. For detailed instructions concerning the investigation of gums, see Wasig's *Die Wichtigsten Handelssorten des Arabischen Gummi*. The large number of gums which have thus been suggested represent all grades and combinations of these properties. Most prominent among them is the group derived from other than the official species of acacia and related genera.

A. Nilotica Desf. is said to yield most of the *Barbary, Morocco,* or *Mogador gum*. *A. Arabica* Willd. and *A. Seyal* Del. often are named as sources of acacia, but their product is dark colored. That of the latter is called *Talea gum*. The names *Gedda, Ghedda, Gehzirah, Kassala, Massowah,* and *Sennaar,* are applied variously to these inferior Nile gums, which usually have a sour or fermented odor. Much poor gum is yielded also by *A. horrida* Willd. (*Cape* or *Angra Pequena gum*) and *A. giraffæ* Willd. (*Camelthorn gum*) of South Africa; *A. pycnantha* Benth. (*Golden wattle gum*—for its properties see *Proc. Am. Pharm. Assoc.*, 1890, 416), *A. decurrens* Willd. (*Tan wattle gum*), *A. homalophylla* A. Cunning. (*Myall gum* or *Myall-wood gum*), and various other species of Australia; *A. speciosa* Willd. (*Kurnool* or *Siris gum*), *A. leucophœa* Willd. (*Delhi* or *Coromandel gum*), *A. odoratissima* Willd., and *A. Sundra* of India;

A. gummifera Willd. (*Morocco gum*); *A. Ehrenbergiana* Hayne, *A. stenocarpa* Hochst. (one of the Nubian or Abyssinian gums called *Savakin* or *Suakim gum*, yielded also by *A. fistula* Schweinf.), and *A. Etbeica* Schweinf., all of northern Africa and all yielding dark-colored gums. *A. albida* Delile and *A. mellifera* Benth. are diffused widely through Africa. Of plants related to acacia, which yield such gums, mention may be made of *Prosopis juliflora* DC. (*Algaroba j.* Benth.; *Acacia j.* Willd.; *P. glandulosa* Torr; *Algaroba g.* T. et G.), of the southwestern United States, which yields an excellent gum (*Mesquit gum*), but in small and irregular quantities, as does *P. spicigera* L. One or more species of *Albizzia*, as well as of *Sophora*, are said to yield similarly. The gum of *Bauhinia retusa* Roxb. yields a mucilage about six times as viscous as that of acacia. Other inferior gums of India which are apparently derived from species of *Acacia* or related genera, are the *Amra*, or *Oomra*, and several varieties of *Amrad* gums.

Of gums of this class produced by plants not related to *Acacia*, few have here attained commercial importance, though a number are used rather extensively in India. Of these, the following deserve mention:

Jingan gum, from *Odina Wodier* Roxb. (Fam. *Anacardiaceæ*).—Abundant and widely distributed in India, exuding from wounds intentional or accidental, whitish to yellow, and much resembling gum arabic, or, if mixed with rain-water when exuding, blackish. Largely used in India, mostly mixed with other gums, for sizing calico and in whitewash. Soluble, if of good quality, in twice its weight of water, forming a thin mucilage about three-fourths as viscous as acacia mucilage (Dunstan). Insipid but containing a little sugar.

Assam or *Bangalore gum*, from *Azedirachta Indica* Juss. (Fam. *Meliaceæ*), dark-colored, the solution wine-colored, with a crystalline sediment; *Islambad* or *Deccan gum*, from *Conocarpus latifolius* Roxb. (Fam. *Combretaceæ*), light-colored and of good quality, but little accessible; *Lahore gum*, from *Anageissus latifolia* Wall. (Fam. *Combretaceæ*), very similar to last, but containing many impurities; *Guzerat* or *Wood apple gum*, from *Feronia elephantum* W. et A. (Fam. *Rutaceæ*), similar to last; *Schajua*, *Mocharras*, or *Jhelam gum*, from *Moringa pterygosperma* Gærtn. (Fam. *Moringaceæ*), reddish and yielding a red solution, believed to be artificially colored; one from *Buchanania latifolia* Roxb. (Fam. *Anacardiaceæ*), its mucilage about two and a half times as viscous as that of acacia; one from *Boswellia serrata* Roxb. (Fam. *Burseraceæ*); *Leopard tree gum*, from *Flindersia maculosa* F. von Mueller (*Elæodendroa m.* Lindl.—Fam. *Meliaceæ*), of Australia, is reported by Maiden as a good substitute for acacia. *Cochlospermum gossypium* DC. (Fam. *Bixaceæ*) yields the *Hogg-gum* or *Kathira* of India. *Hog* or *Doctor's gum* is yielded by *Moronobea coccinea* Aubl. (Fam. *Guttiferæ*), and probably *Rhus metopmum* L. *Chagual gum*, of Chili, is yielded by *Puya lanuginosa* Molina (*Pourretia l.* R. et P.), *P. Chileasis* Mol., *P. tuberculata* Mart., and *P. lanata* Schult. (Fam. *Bromeliaceæ*).

Of purely artificial substitutes, dextrin and starch are considered elsewhere.

Schumann's Universal Gum was made by allowing sulphuric acid to act upon starch at a high temperature and under pressure, neutralizing and drying to a proper consistency. On hardening, it closely resembles acacia in appearance and adhesiveness.

Another of these products is made by boiling 10 Kg. of linseed oil with 80 Kg. of sulphuric acid and 100 liters of water for 3 or 4 hours, filtering, precipitating with 4 times its volume of alcohol, washing, and drying the precipitate.

Acacine, another of this class, was found unsuitable for emulsions.

ACANTHACEÆ.—The Acanthus Family.

About 175 genera and 1400 species, common in most tropical, scarce in warm-temperate, and wanting in cool countries; largely cultivated for their showy flowers, otherwise of little economic importance; young shoots of a few species used as potherbs; constituents and properties resembling those of the *Labiatæ*, and even more so those of the *Verbenaceæ;* bitter principles are of first, volatile oils and resins of second, and tannin of third importance, with a few alkaloids. This composition indicates the properties.

Probably the most largely used drug of this family is the herb of *Andrographis paniculata* Nees, which is collected largely from both wild and cultivated plants throughout India for its medicinal properties. It contains an unstudied bitter principle, and is used as a bitter tonic, substituting gentian and chirata. Its identification is considered under the last-mentioned title.

Adhatoda vasica Nees (*Arusa*, *Adulsa*, etc.), an Indian shrub, is employed widely as an aromatic expectorant and anthelmintic, besides which it has a very curious use in the destruction of aquatic weeds which infest inundated rice-fields. It also possesses the power of destroying other low forms of vegetable as well as insect life. It contains the alkaloid *vasicine*, which appears to have the same destructive property. This alkaloid has been experimented with in medicine to some extent, but without definite result. *Ruellia hirsuta* Nees, of Java, and *Leptostachya nitida* Nees, of South America, yield blue dyestuffs. *Justicia Gendarussa* L., and many other species of *Justicia*, have domestic repute as astringents, while various others are used as aromatics. The wood of *Paulowilhelmia speciosa* Hochst. (*Adubiri* or *Aquapim*), of Africa, is used as a fish poison. *Asteracantha longifolia* (L.) Nees is used as a powerful diuretic and diaphoretic. *Ecbolium Linneanum* Kurz (*Udwjati* or *Ran-oboli*), of Arabia, is a much-used diuretic in renal and cystic calculus and gout, as well as an expectorant. *Barleria prionitis* L. (*Jhinta*,

Kantajati, Coletta, Veatla, etc.), of India, containing much resin, is also a much-used diaphoretic and expectorant. *Acanthus ilicifolia* L. (*Harkuchkanta, Marandi*, or *Moranna*), of India, contains an alkaloid, and the entire plant, as well as the root separately, is used as a mucilaginous expectorant. *Hygrophila spinosa* T. And. (*Talmakhara, Kolista, Ikshura*, etc.), and other Indian species of this genus, are diuretic and the seeds much-used aphrodisiacs. The seeds of *Crossandra undulæfolia* Salisb., and of *Blepharis edulis* Pers. (*Utanjan, Anjurah*), of India and Persia, containing a bitter principle, apparently a glucoside, are used also as aphrodisiacs. *Rhinacanthus communis* Nees (*Pelak-juhi*, etc.) is prized highly in India as an application in ringworm and other cutaneous diseases. Since it invariably appears to be used as one of several ingredients of a mixture, its effect is problematical.

(*References.*—Dymock and Hooper, *Pharm'g'a Ind.;* Dethan, *Les Acanthacées;* Boorsma, *Ueber einige neuere Analysen, Med. uit's Land Pl.*)

ACETANILIDUM, *U. S., Br., P. G.*—Acetanilide.

Antifebrinum, P. A.; *Phenylacetamide, Acetylamidobenzene, Antifebrin*, E.; *Acetanilide*, Fr.; *Antifebrin*, G.

Formula, $C_6H_5NH.C_2H_3O$ or $C_6H_5NH.CH_3CO$. Molecular weight, 134.09.

Preparation.—Acetanilide was prepared first by Gerhard in 1852, by acting upon aniline with acetyl chloride or with acetic anhydride. It is manufactured by moderately boiling in a retort, connected with a reflux condenser, equal parts of aniline and glacial acetic acid until a small portion, removed from the retort, will congeal on cooling; the mass then is distilled, when water and acetic acid will pass over, and finally acetanilide, which is recrystallized from boiling water. The new compound is formed by elimination of water, according to the equation: $C_6H_5NH_2 + CH_3COOH = C_6H_5NHCH_3CO + H_2O$.

Properties.—Acetanilide forms colorless glistening scales or a white shining crystalline powder, not altered by exposure to air or light, free from odor, but having a somewhat pungent, slightly burning taste. It melts at 113° C. (235.4° F.), boils at 295° C. (563° F.) without decomposition, and when ignited upon platinum-foil burns without leaving a residue. It is soluble in 194 parts of water at 15° C. (59° F.) (200 parts, Br.; 230 parts, P. G.); also in 5 parts (4 parts, Br.; 3.5 parts, P. G.) of alcohol, in 18 parts of ether, and is easily soluble in chloroform and benzene; but slightly soluble in carbon disulphide. At 25° C. (77° F.) it is soluble in 179 parts of water, 2.5 parts of alcohol, 12 parts of ether, or 5 parts of chloroform; it is also soluble in 18 parts of boiling water and in 0.4 parts of boiling alcohol (U. S.). The solutions have a neutral reaction to test-paper.

The tests of identity and purity adopted by the different pharmacopœias are nearly identical. The solution of acetanilide in sulphuric acid without the production of a dark color indicates the absence of dust, saccharine matter, and many organic compounds. On heating about 0.1 Gm. of acetanilide with 5 Cc. of concentrated solution (1 in 4) of potassium or sodium hydroxide, the characteristic odor of aniline becomes noticeable; on now adding 1 Cc. of chloroform and again heating, the disagreeable odor of *phenyl isocyanide* is evolved (distinction from *methylacetanilide* or *antipyrine*) (U. S.). Analogous reactions are produced by all primary amines, as was shown by A. W. Hofmann (1875), who discovered this compound, known also as *phenylcarbylamine* or *isonitrile*, C_6H_5NC, which has a repulsive, penetrating odor and is very poisonous. On boiling 0.1 Gm. of acetanilide for several minutes with 2 Cc. of hydrochloric acid, a clear solution results, which, when mixed with 3 Cc. of a 5 per cent. aqueous solution of phenol, and afterward with 5 Cc. of a filtered saturated solution of chlorinated lime, acquires a brownish-red color, becoming blue upon supersaturation with ammonia-water (U. S.). This is the so-called indophenol or indo-aniline reaction, which is shown also by phenacetin and other allied compounds, from which acetanilide may be distinguished by the melting-point and solubility. A cold saturated aqueous solution of acetanilide added to ferric chloride test-solution should not affect the color of the latter (U. S.). This test shows the absence of aniline salts, of antipyrine, hydracetin, and some other compounds; on the application of heat the mixture of acetanilide and ferric salt becomes deep red. On heating 0.1 Gm. of acetanilide with 10 Cc. of water, and filtering the solution when cold, and adding bromine test-solution, drop by drop, to the filtrate, a whitish precipitate of *parabromacetanilide* is formed (distinction from *antipyrine* or *acetphenetidin*) (U. S.).

A number of mixtures of from 50 to 90 per cent. of acetanilide with sodium bicarbonate, and in some cases with ammonium bromide, salicylic acid, and other compounds, have been introduced as proprietary articles and sold under copyrighted names.

Action and Uses.—Acetanilide was introduced into medicine first as an antipyretic, but later studies have shown it to possess even greater powers as an analgesic.

In ordinary dose the drug exercises a sedative influence upon the sensory nervous system, toxic doses causing paralysis, loss of reflex action, and anæsthesia. Upon the circulation it has little or no effect; in poisonous dose it acts as a cardiac and vascular depressant.

Acetanilide in overdoses reduces hæmoglobin to methæmoglobin, diminishes the oxygen-carrying power of the blood, and in excessive quantities produces corpuscular destruction. Ordinary doses, however, produce no such change. Temperature is lowered by increasing heat-dissipation and by decreasing heat-production, and not by the free sweating which commonly follows its administration. The excretion of urea and uric acid is increased by acetanilide, which itself is eliminated by the kidneys as paramido-phenol-sulphate.

In certain individuals who have an idiosyncrasy to the drug a number of untoward symptoms have been noted; the most common being cyanosis, excessive sweating, collapse, and occasionally erythematous rashes.

The treatment of poisoning by acetanilide consists in the application of external heat and the administration of stimulants. Strychnine and caffeine in full doses to aid the respiration, belladonna to maintain the blood-pressure, and if cyanosis be marked inhalations of oxygen, may be used with benefit.

Acetanilide, as an antipyretic, was at one time recommended and indiscriminately employed in the reduction of all febrile conditions, but is now used only where there are certain definite indications.

It is contraindicated in all adynamic conditions, especially the low fevers, as it tends to greater depression and in no way influences their course or duration for better. It is inadvisable to employ it as a remedy in tuberculosis, as it may cause profuse sweats, cyanosis, and collapse.

In the treatment of sthenic fevers the drug may be employed, especially in the exanthemata and in those diseases incident to childhood. It should be employed with caution in the treatment of croupous and bronchopneumonia.

The drug finds its true value in combating the various forms of nerve pain; for example, the crises of locomotor ataxia, gastralgia, and intercostal and other forms of neuralgia. It has been employed in sciatica, lumbago, chronic muscular rheumatism, and in rheumatic fever with benefit, although in the latter it may cause excessive sweating. Acetanilide has proved efficient in the treatment of certain cases of epilepsy, and in others has been given without result. It has been recommended in delirium tremens, congestive headache, pertussis, and other reflex coughs, and in the pain resulting from senile gangrene and cancer, but it is practically valueless in pain the result of inflammation or traumatism.

Locally, acetanilide has been employed in the treatment of epistaxis and as an antiseptic dusting-powder for dressing wounds, chancroids, and chronic ulcers.

As an antipyretic it is usually given in doses of from 3 to 5 grains (0.20–0.30 Gm.), as an anodyne, from 1 to 3 grains (0.065–0.20 Gm.), every 4 or 5 hours.

Allied Compounds and Derivatives.—ACETBROMANILIDE.—*Parabromacetanilide; Antisepsin; Asepsin.* $C_6H_4Br.NH.CH_3CO$.—It is obtained by adding 160 parts of bromine to a solution of 135 parts of acetanilide in glacial acetic acid, and subsequently crystallizing the resulting white precipitate from hot alcohol. Colorless needles, melting at 165.5° C. (330° F.), which owing to their sparing solubility are tasteless. Antisepsin should not be confounded with antiseptin, which is a mixture of zinc sulphate, thymol, zinc iodide, and boric acid. The former possesses analgesic and antipyretic properties, and may be employed for the same purposes as acetanilide. Dose, 3 to 10 grains (0.20–0.60 Gm.).

AMMONIATED ACETANILIDE.—Under this name the following mixture has been recommended as causing less depression than acetanilide: acetanilide, 25 parts; sodium bicarbonate, 5 parts; ammonium carbonate, 10 parts; and milk-sugar, 60 parts.

BENZANILIDE.—*Benzoylanilide; Phenylbenzamide.* $C_6H_5NHCOC_6H_5$.—It is produced by the action of benzoic anhydride, benzoic acid, or of benzoyl chloride upon aniline, and crystallization from alcohol. It forms small white scales of a pearly lustre, inodorous, tasteless, insoluble in water, and fusible at about 162° C. (323.6° F.). Benzanilide may be employed as an antipyretic. As it is less depressing than acetanilide, it is said to be the better remedy to employ in children. The dose is from 1 to 5 grains (0.005–0.30 Gm.).

DIACETANILIDE. $C_6H_5N(CH_3CO)_2$.—This compound is obtained by heating acetanilide with glacial acetic acid to 200°–250° C. (392°–482° F.) and extracting the mass with hot benzin, from which the diacetanilide will crystallize in colorless leaflets melting at 110° C. (231.8° F.).

Formanilide.—*Phenylformamide.* $C_6H_5NH.HCO$.—It may be obtained by heating aniline with ethyl formate or by distilling a mixture of aniline 93 parts and anhydrous oxalic acid 90 parts, and occurs in colorless prisms, melting at 46° C. (114.8° F.). Formanilide is fairly soluble in water and readily in alcohol; also soluble in glycerin and fixed oils. Formanilide is also an antipyretic and analgesic in doses of from 2 to 5 grains (0.10–0.30 Gm.). Locally applied to mucous membranes it produces anæsthesia, and a 3 per cent. solution when injected subcutaneously may be employed as a local anæsthetic.

Gallanilide.—*Gallanol; Gallinol.* $C_6H_5NH.CO.C_6H_2(OH)_3 + 2H_2O$.—If gallic acid be heated for 1 hour with an excess of aniline at a temperature of 150° C. (302° F.) and the mixture then treated several times with very dilute hydrochloric acid, the residue will consist of gallanilide, which may be crystallized from boiling water. The crystals are colorless and become anhydrous at 100° C. (212° F.). It is readily soluble in alcohol, ether, and boiling water; sparingly in cold water. Ointments containing from 5 to 20 per cent. of gallinol may be employed as substitutes for chrysarobin in the treatment of certain skin affections (see Chrysarobin), as it is stated to be less irritating than the latter drug and non-poisonous.

Methylacetanilide.—*Exalgine.* $C_6H_5N(CH_3)CH_3CO$.—It may be obtained by gradually adding acetyl chloride to monomethylaniline; heat is developed and the following reaction occurs: $2C_6H_5NH(CH_3) + CH_3COCl = C_6H_5N(CH_3)CH_3CO + C_6H_5NHCH_3HCl$; both methylacetanilide and methylaniline hydrochloride being formed, which may be separated by crystallizing from boiling water, when the former will be obtained in colorless needles or prisms. It is inodorous and tasteless, and melts at 102° C. (215.6° F.) in air or at 98° C. (208.4° F.) under water. It is neutral to test-paper, freely soluble in alcohol, chloroform, and boiling water; also soluble in 60 parts of cold water or 10 parts of ether. On heating it with potassium hydroxide and then with chloroform, the disagreeable odor of isonitril is not produced, but a faint, rather pleasant odor is observed (distinction from acetanilid). Exalgine may be employed interchangeably with acetanilide or antipyrine as an analgesic, but not as an antipyretic. It is commonly employed for the relief of pain occurring in certain nervous affections, for example, locomotor ataxia. Dose, 3 to 10 grains (0.20–0.60 Gm.).

Salicylanilide. $C_6H_5NH.C_6H_4(OH)CO$.—It may be obtained by heating a mixture of aniline, salicylic acid, and phosphorus trichloride. After washing the product with water it is dissolved in dilute solution of sodium hydroxide, precipitated by addition of hydrochloric acid, and crystallized from alcohol. It occurs in colorless prisms, melting at 134.5° C. (274.1° F.), and freely soluble in alcohol, ether, and chloroform, but sparingly in hot or cold water. This compound should not be confounded with the commercial article *salifebrin*.

ACETONUM, *U. S.*—Acetone.

Spiritus (*s. Æther*) *Pyroaceticus.—Pyroacetic spirit or ether, Dimethylketone,* E.; *Acétone, Ether* (*Esprit*) *pyroacétique,* Fr.; *Aceton, Essiggeist, Mesitalkohol,* G.; *Chetone, Metilacetone,* It.

Formula, C_3H_6O or CH_3COCH_3. Molecular weight, 57.61.

A liquid containing not less than 99 per cent. by weight of absolute acetone (dimethylketone). It should be kept in well-closed vessels in a cool place, remote from lights or fire.—U. S.

Formation and Preparation.—Acetone is formed on the dry distillation of wood, of acetates, citric acid, and, in the presence of lime, from sugar and other carbohydrates. It may be obtained nearly pure by the dry distillation of barium acetate (Liebig), but is prepared usually from calcium acetate or from a mixture of 4 parts of crystallized lead acetate and 1 of burnt lime; the distillate is neutralized with dry sodium carbonate, treated with calcium chloride, and purified by fractional distillation over lime.

Acetone may be obtained in large quantities by decomposing acetic acid vapor at a high temperature, between 500° and 600° C. (932° and 1112° F.), in specially constructed iron cylinders, as shown by Squibb in 1895 (*Ephemeris,* vol. iv.), and the product subsequently dehydrated with quicklime and redistilled. The decomposition of the acid vapor occurs as follows: $2HC_2H_3O_2 = C_3H_6O + CO_2 + H_2O$.

Acetone has been found to be a most excellent solvent for tannin, and has been used successfully in the preparation of oleoresins, in place of ether. It is the richest chloroform-yielding substance known, and since 1885 has been used for this purpose almost to the exclusion of alcohol in this country.

Properties.—It is a thin colorless liquid, which, when ignited, burns with a luminous, non-sooty flame. It has a peculiar ethereal, somewhat mint-like odor, and a refreshing but very pungent and sweetish taste. Its density at 15.6° C. (60° F.) is 0.800 or 0.790 at 25° C. (77° F.); it boils at 56.5° C. (133.7° F.). It is soluble in all proportions in water, alcohol, ether, volatile oils, and most compound ethers; dissolves gun-cotton, camphor, many resins (including copal), and fats; and forms crystal-

line compounds with the alkali bisulphites. Most of the salts soluble in alcohol are insoluble in acetone, which separates even from a concentrated aqueous solution of calcium chloride.

Tests.—Acetone should not affect the color of blue or red litmus-paper previously moistened with water. If 50 Cc. of acetone be evaporated in a clean glass vessel, no weighable residue should remain. If 20 Cc. of acetone contained in a clean glass-stoppered vial be mixed with 0.1 Cc. of one-tenth normal potassium permanganate solution, the pink tint produced by the admixture should not wholly disappear in less than 15 minutes (limit of *empyrheumatic substances*).—U. S.

Action and Uses.—Acetone was formerly used in medicine to reduce the temperature, allay the cough, and diminish the expectoration in pulmonary tuberculosis and chronic bronchial affections. It has been employed in rheumatism and gout, in vomiting the result of either functional or organic disease, and in diarrhœa and dysentery. In overdose it produces intoxication, and when inhaled is probably a slight anæsthetic, causing considerable bronchial irritation. Acetone is sometimes found in the urine in cases of advanced diabetes mellitus, and occasionally in that of healthy individuals who subsist largely upon proteid diet.

It may be prescribed in doses of 15 or 20 minims (1–1.3 Cc.) dissolved in spirit of nitrous ether.

Allied Compounds.—ACETOPHENONE; *Phenyl-methylacetone, Phenylmethylketone, Hypnone.* $C_6H_5COCH_3$.—This compound was first produced by Friedell by the dry distillation of a mixture of calcium benzoate and acetate in molecular proportions. It may also be obtained by the action of zinc methyl on benzoyl chloride, or by boiling benzene with acetyl chloride and aluminum chloride and subjecting the product to fractional distillation, that portion distilling between 195° and 200° C. (383°–392° F.) being collected separately and cooled until it crystallizes. Acetophenone is a colorless or yellowish mobile liquid, having a persistent odor of bitter almond and orange, and a pungent taste. It boils at 210° C. (410° F.), and congeals at —4° C. (24.8° F.), forming white laminæ, which if pure melt at 20° C. (68° F.). It has the specific gravity 1.035, remains for some time suspended in water in the form of globules, is almost insoluble in water, dissolves in 60 parts of glycerin, and is freely soluble in alcohol, ether, chloroform, benzene, and fixed oils. Hypnone, or acetophenone, is hypnotic and slightly anodyne. The drug is unreliable, and frequently fails to produce sleep in the presence of pain or great nervous excitement. It is objectionable also because it disorders digestion, imparts a disagreeable odor to the breath, and has a very offensive taste. Hypnone may be given in capsules containing from 1 to 5 minims (0.05–0.30 Cc.).

SALACETOL; *Salicyl-acetol, Sulantol.* $C_6H_4(OH)CO_2CH_2COCH_3$.—This is a compound resembling salol, except that the phenyl group, C_6H_5, has been replaced by the radical CH_2COCH_3, derived from acetylmethyl alcohol, also known as *acetol.* If sodium salicylate be heated with monochloracetone, sodium chloride and the salicylic acid ester of acetol are formed; thus, $C_6H_4(OH)CO_2Na + CH_2ClCOCH_3 = NaCl + C_6H_4(OH)CO_2CH_2COCH_3$. The sodium chloride is removed by treatment with water. Salacetol occurs in colorless scales or needles having a faintly bitter taste and melting at 71° C. (159.8° F.). It is soluble in 15 parts of alcohol, 25 parts of castor oil, or 30 parts of expressed oil of almond, but requires 2200 parts of cold water for solution. It is soluble in a 1 per cent. solution of sodium hydroxide, but undergoes decomposition. Salacetol should not be confounded with *salactol*, a solution of sodium salicylate and lactate in a 1 per cent. solution of hydrogen peroxide. Salacetol possesses germicidal properties, and has been employed in the treatment of summer diarrhœa, dysentery, and choleraic diarrhœa. It is stated that the drug is less poisonous than salol, and for this reason is especially serviceable in infantile affections. It may be employed alone or given in conjunction with castor oil. The ordinary dose for an adult is from 20 to 40 grains (1.30–2.60 Gm.), and for a child from 5 to 8 grains (0.30–0.50 Gm.) daily.

ACETPHENETIDINUM, *U. S.*—Acetphenetidin.

Phenacetinum, Br., P. G.; *Acet-Phénétidine*, Fr. Cod.—*Phenacetin, Para-acetphenetidin, Para-ethoxyacetanilide*, E.; *Phénacétine, Para-acetophénétidine, Amide acétique de l'amido-phénétol*, Fr.; *Phenacetin*, G.

A phenol derivative, acetparaphenetidin, the product of the acetylization of paraamidophenetol.—U. S.

Formula: $C_6H_4(OC_2H_5)NH.C_2H_3O$ or $C_2H_5O.C_6H_4.NHCOCH_3$. Molecular weight, 177.79.

The use of the official titles Acetphenetidin and Phenacetin is about equally divided among the leading pharmacopœias, the former being employed in the United States, French, and Austrian pharmacopœias, while the British, German, and Swiss pharmacopœias prefer the latter name.

Preparation.—None of the pharmacopœias give a process of manufacture. The following reactions occur during the preparation. When slightly diluted nitric acid, or a mixture of sulphuric acid and solution of sodium nitrate, is allowed to act on melted phenol, ortho- and para-nitrophenol are formed, the liberated water being taken up by the sulphuric acid, thus: $C_6H_5OH + HNO_3 = C_6H_4(NO_2)(OH) + H_2O$; as the para-nitrophenol is not volatile, the two varieties are separated by distillation with steam, the residuary para-compound being afterward decolorized with animal charcoal and crystallized. By action of sodium hydroxide, sodium nitrophenol, $C_6H_4(NO_2)(ONa)$, is formed, which is heated with ethyl iodide and converted into para-nitrophenetol, thus: $C_6H_4(NO_2)(ONa) + C_2H_5I = C_6H_4(NO_2)(OC_2H_5) + NaI$. The latter compound, by action of nascent hydrogen, obtained from zinc and hydrochloric acid, is converted into para-amidophenetol or paraphenetidin, thus: $C_6H_4(NO_2)(OC_2H_5) + H_6 = C_6H_4(NH_2)(OC_2H_5) + 2H_2O$. By prolonged boiling with glacial acetic acid, paraphenetidin is converted into para-acetphenetidin, just as aniline is converted into acetanilide.

Properties.—Acetphenetidin occurs as white, glistening, crystalline scales or fine crystalline powder, odorless and tasteless. It is soluble in 925 parts of water, 12 parts of alcohol, 63 parts of ether, and 20 parts of chloroform at 25° C. (77° F.), in 70 parts of boiling water and 2 parts of alcohol at 80° C. (176° F.).—U. S. Very sparingly soluble in cold water, more freely in boiling water, soluble in 20 parts of 90 per cent. alcohol, Br, ; soluble in 1400 parts of cold water, about 70 parts of boiling water, and also in 16 parts of alcohol, P. G. Its solutions are neutral. Heated to 135° C. (275° F.) it melts, and at a higher temperature burns without leaving a weighable residue. Acetphenetidin dissolves without color in sulphuric acid, but if shaken with nitric acid is colored yellow, which color persists when heated.—U. S. In the system it is decomposed into phenetidin, $C_6H_4(NH_2)(OC_2H_5)$, and amidophenol, $C_6H_4(NH_2)(OH)$.

Tests.—"If 0.1 Gm. of acetphenetidin be boiled for 1 minute with 1 Cc. of concentrated hydrochloric acid and the solution diluted with 10 Cc. of water, cooled, and filtered, it should yield on the addition of 3 drops of a 3 per cent. solution of chromium trioxide a ruby-red color. On heating 0.1 Gm. of acetphenetidin with 5 Cc. of a concentrated solution (1 in 4) of potassium hydroxide, the odor of aniline should not be perceptible. If 0.1 Gm. of acetphenetidin be boiled with 10 Cc. of water, it should yield a solution which, when cooled and filtered, should not become turbid upon the addition of bromine-water in slight excess (absence of *acetanilide*). If 0.1 Gm. of acetphenetidin be boiled for 1 minute with 3 Cc. of solution of sodium hydroxide (1 in 2), the solution cooled, and then agitated with 5 Cc. of solution of chlorinated soda, there should be produced a clear yellow liquid, and not a purplish-red or brownish-red cloudy liquid or precipitate (absence of *acetanilide*). A mixture of 0.3 Gm. of acetphenetidin with 1 Cc. of 90 per cent. alcohol should not acquire a red tint when diluted with 3 times its volume of water and boiled with 1 drop of volumetric iodine solution (absence of *paraphenetidin*)."—U. S.

The ruby-red color mentioned in the first test is caused by the action of chromic acid on the phenetidin liberated by the hydrochloric acid, and may be obtained with chlorine-water and other oxidizing agents as well. It serves to distinguish acetphenetidin from acetanilide and exalgine.

Action and Uses.—Acetphenetidin is employed in medicine for the reduction of fevers and the relief of pain. Although introduced chiefly for the former purpose, it is rarely used as an antipyretic at this time, its chief employment being for the relief of various neuralgic pains and of the nerve pains which arise from chronic diseases of the nervous system, notably locomotor ataxia. Its action in reducing fever is practically identical with that of antipyrine and acetanilide, the fall in temperature being due to a decrease in heat-production and an increase in heat-dissipation. Upon the heart it exercises very little effect, being a feeble cardiac depressant. Upon the respiration it exercises no influence. On the nervous system its dominant influence is upon the sensory portions of the brain, the spinal cord, and the sensory nerves. It has been employed in epilepsy as a nervous sedative, but with very little result. When used for neuralgic pains, it is commonly combined with caffeine and one of the bromides, which materially assist it in its direction. If employed for the reduction of fevers, it should be used in the treatment of acute sthenic fevers and not in the course of prolonged exhausting fevers like typhoid fever or the hectic fever of tuberculosis, in which latter disease it is apt to increase cyanosis and the night-sweats. Taken in overdose acetphenetidin produces

feebleness of the circulation and more or less cyanosis, which is chiefly due to the production of methæmoglobin in the blood. This cyanosis disappears as soon as the drug is eliminated from the body, from which it escapes chiefly through the kidneys. The dose of acetphenetidin is usually 5 grains, which may be repeated in an hour or two if necessary.

Acetphenetidin has the reputation among clinicians of being less depressant to the circulation in cases of feebleness than are antipyrine and acetanilide.

Derivative and Allied Compounds.—The following derivatives of phenetidin, and compounds allied to phenacetin are of more or less interest to physicians and pharmacists:

Amygdophenin.—*Amygdalyl-p-phenetidin.* $C_6H_4(OC_2H_5)NH(CO.CH.(OH).C_6H_5)$.—This is prepared by heating 137 parts of *p*-phenetidin with 152 parts of mandelic acid to about 150° C. (302° F.) until all water is expelled, washing the product with dilute sodium hydroxide solution, and crystallizing from ether-alcohol mixture. It occurs as a white crystalline powder, or glistening scales, melting at 140.5° C. (284.9° F.). It is readily soluble in alcohol, difficultly soluble in hot water, ether, benzene, and almost insoluble in cold water. Amygdophenin has been recommended in the treatment of rheumatic fever, but its use is limited. The dose is stated to be from 10 to 15 grains (0.65–0.97 Gm.) every 4 or 5 hours. It is best administered either in powder or in tablet.

Apolysin.—*Monophenetidin Citrate.* $C_6H_4(OC_2H_5)NH.[COC_3H_4(OH)(CO_2H)_2]$.—55 parts of *p*-phenetidin and 84 parts of citric acid are heated several hours between 100° and 200° C. (212° and 392° F.), the resulting product treated with solution of sodium carbonate, which leaves diphenetidin citrate undissolved. The soda solution is then acidulated with hydrochloric acid and the liberated monophenetidin citrate purified by recrystallization. A white crystalline powder, or large colorless hygroscopic crystals, having a peculiar odor, an acidulous taste, and acid reaction. The crystals melt at 72° C. (161.6° F.), and are soluble in 25 parts of cold water, in about 1 part of boiling water, and quite readily in alcohol and glycerin. They dissolve colorless in concentrated sulphuric acid, but yield a pale orange-colored solution with nitric acid. Dried at 100° C. (212° F.) the crystals lose 1 molecule of water and the product then has a melting-point of 129° C. (264.2° F.). The dose is from 5 to 10 grains (0.3–0.65 Gm.).

Benzacetin.—*Acet-amido-ethyl-salicylic Acid.* $C_6H_3(OC_2H_5)(NH.COCH_3)CO_2H$.—It occurs as colorless crystals, melting at 189° to 190° C. (372.2°–374° F.), which are soluble in alcohol and aqueous alkaline solutions, but difficultly soluble in cold water.

Citrophen. $[C_6H_4(OC_2H_5)NHCO]_3.C_3H_4(OH)$.—411 parts of *p*-phenetidin and 210 parts of citric acid are heated in presence of a dehydrating agent, the product washed with dilute aqueous solution of sodium hydroxide, and finally crystallized from water. A white crystalline powder having an acidulous aromatic taste and acid reaction, melting at 181° C. (357.8° F.). The crystals are difficultly soluble in cold water, but soluble in about 15 parts of boiling water. The aqueous solution is turned dark red by ferric chloride and violet by chromic acid. Or, if subjected to the fumes of nitric acid, and then treated with excess of ammonia, a bright-red precipitate results. Uses identical with acetphenetidin. Dose, 5 to 10 grains (0.3–0.65 Gm.).

Formylphenetidin.—*Formphenetidid; p-Ethoxyformanilide.* $C_6H_4(OC_2H_5)NH.HCO$.—Colorless, odorless, tasteless crystalline scales, difficultly soluble in cold water, soluble in hot water, in alcohol and ether, and melts at 69° C. (156.2° F.).

Iodophenin.—*Iodophenacetin; Tri-iododiphenacetin.* $(C_6H_4OC_2H_5NHCH_3CO)_2I_3$.—To a solution of phenacetin in glacial acetic acid are added some moderately diluted hydrochloric acid and a solution of iodine and potassium iodide in water, when upon cooling steel-blue crystals of iodophenin will be deposited. They are almost insoluble in water and difficultly soluble in benzene and chloroform, but are more readily soluble in alcohol, glacial acetic acid, and boiling hydrochloric acid. Iodophenin has a feeble iodine-like odor, a burning taste, and colors the skin yellow. It contains about 50 per cent. of iodine and melts at 130° C. (266° F.) with decomposition.

Kryofin.—*Methoxacetparaphenetidin; Methylglycollicphenetidin.* $C_6H_4OC_2H_5NH[(CH_3O)CH_2CONH]$.—Colorless crystalline needles melting at 98° to 99° C. (208.4°–210.2° F.), and soluble in about 600 parts of cold water, in 52 parts of boiling water, and in alcohol, ether, and chloroform.

Lactophenin.—*Lactyl-phenetidin.* $C_6H_4(OC_2H_5)NH.(COCH[OH]CH_3)$.—It is prepared by heating lactic acid with *p*-phenetidin to 180° C. (356° F.) until all water is expelled, and the resulting product then crystallized from hot water. A white colorless, odorless, slightly bitter crystalline powder, melting at 117.5° to 118° C. (243.5°–244.4° F.). It is soluble in 500 parts of cold water, in 55 parts of water at 100° C. (212° F.), in 8.5 parts of alcohol at 15° C. (59° F.), and difficultly soluble in ether and petroleum ether. The solutions are neutral to litmus. It dissolves in sulphuric acid without discoloration. Lactophenin gives the ruby-red coloration with chromic acid (see above). If 0.3 Gm. of finely pulverized lactophenin be mixed with 2 Cc. of nitric acid, and the resulting yellow solution be diluted after 1 hour with water, then filtered and washed with water, the insoluble residuum dried, and crystallized from benzene should have a melting-point of 96.5° C. (205.7° F.). By heating the residuum with alcoholic potassium hydroxide a dark yellowish-red solution results, which on cooling deposits red crystals having a melting-point of 110.5° C. (231° F.), Hager. 0.1 Gm. dissolved in 10 Cc. of boiling water, and the solution filtered after cooling, yields a filtrate which turns turbid on addition

of sufficient bromine-water to produce a yellow color (distinction from *phenacetin*). Its uses and dose are identical with acetphenetidin.

MALAKIN.—*Salicyliden-p-phenetidin.* $C_6H_4(OC_2H_5)N : CH.C_6H_4.OH + H_2O$.—Fine yellowish needles, melting at 92° C. (197.6° F.), insoluble in water, soluble in hot alcohol, in ether, and benzene. In sodium hydroxide solution the crystals dissolve with the production of a yellow-colored solution. Mineral acids decompose it into *p*-phenetidin and salicylaldehyde. Malakin contains about 50 per cent. of salicylaldehyde.

METHACETIN.—*Para-acetanisidin, Para-methoxyacetanilide.* $C_6H_4OCH_3NHC_2H_3O$.—This, the most formidable rival of phenacetin, differs from the latter, as the formula shows, in the substitution of a methyl group in place of an ethyl group. The process for its manufacture is identical with that for phenacetin, except that methyl iodide or chloride is used in place of the respective ethyl compound. It occurs in lustrous scaly crystals, colorless, odorless, and melting at 127° C. (260.6° F.). It sublimes at higher temperatures without decomposition. Methacetin is soluble in 350 parts of water at 15° C. (59° F.), and in 12 parts at 100° C. (212° F.); it is abundantly taken up by alcohol, acetone, chloroform, glycerin, and fixed oils. It may be distinguished from phenacetin by melting to an oily liquid if heated with water in insufficient quantity for solution, phenacetin being unaffected by this treatment; the liquid solidifies again on cooling. Its color-reactions are similar to those of phenacetin. It has been recommended as an antipyretic and analgesic in much smaller doses than phenacetin.

PHENOCOLL HYDROCHLORIDE.—*Amido-acetparaphenetidin Hydrochloride; Phenamin.* $C_6H_4.OC_2H_5(NHCOCH_2NH_2).HCl$.—By the action of chloracetylchloride on phenetidin and subsequent treatment of the resulting ethoxymonochloracetanilide with ammonia, a basic compound, known as amido-acetparaphenetidin or glycocollparaphenetidin, is obtained, to which the name phenocoll has been given. If the basic substance be neutralized with hydrochloric acid, the above salt may be obtained in form of a white crystalline powder, which is readily soluble in alcohol and also soluble in 16 parts of water. An aqueous solution of the salt upon addition of alkali hydroxides or carbonates yields a crystalline precipitate melting at 95° C. (203° F.). Ferric chloride should not cause a red color in the aqueous solution, showing the absence of phenetidin. If phenocoll be neutralized with acetic or salicylic acids, the corresponding acetate and salicylate will be formed, which have also been introduced into medicine. The latter salt is also known as salocoll. Like acetphenetidin and similar compounds, it is used as an antineuralgic and antipyretic. In larger doses than are ordinarily employed it has a beneficial effect in acute rheumatic fever. It is claimed by some investigators that the depression caused by the drug is less than that by most other coal-tar antipyretics, also that there is no destruction of red blood-cells. The fall in temperature is due to decreased heat-production, heat-elimination being but slightly affected. When large quantities are ingested, the urine assumes a dark, reddish-brown color. The dose is from 5 to 15 grains (.30–1.0 Gm.), in capsule or solution.

PYRANTIN.—*Phenosuccin; Para-ethoxyphenylsuccinimide.* $C_6H_4(OC_2H_5)N : (COCH_2—CH_2—CO)$.—It is prepared by melting together 1.1 parts of *p*-amidophenol and 1.2 parts of succinic acid at 150°–170° C. (302°–338° F.), and crystallizing the product from alcohol or acetic acid solution. It forms colorless prismatic needles which melt at 155° C. (311° F.). It is soluble in 1700 parts of water at 15° C. (59° F.), in 85 parts of boiling water, insoluble in ether, but readily soluble in hot alcohol and acetic acid, and in solutions of alkalies. The sodium salt forming an odorless crystalline powder of an acidulous saline taste, alkaline reaction, and is readily soluble in water.

SALIPHEN.—*Salicyl-p-phenetidin.* $C_6H_4(OC_2H_5)NH.CO.C_6H_4.OH$.—Colorless crystals, melting at 139.5° C. (283° F.). The crystals are insoluble in water, but soluble in acetone, ether, and boiling alcohol, chloroform, and glacial acetic acid.

THYMACETIN.—$C_6H_2.CH_3OC_2H_5C_3H_7NH.COCH_3$.—Prepared from thymol in a manner similar to that of phenacetin from phenol. A white crystalline powder, slightly soluble in water, soluble in alcohol, and melting at 136° C. (276.8° F.). It is used as an analgesic in doses of from 3 to 15 grains (0.20–1 Gm.).

TRIPHENIN.—*Propionyl-p-phenetidin.* $C_6H_4(OC_2H_5)NH(CO—CH_2—CH_3)$.—Prepared by heating *p*-phenetidin with propionic acid. It occurs as colorless, odorless, slightly bitter crystals, which melt at 120° C. (248° F.). It is soluble in about 2000 parts of water.

VALERIDIN.—*Valerydine; Valeryl-p-phenetidin.* $C_6H_4(OC_2H_5)NH(COC_4H_9)$.—Prepared by heating *p*-phenetidin with valeric acid or valeryl chloride. It occurs as white glistening needles which are soluble in alcohol, but difficultly soluble in ether, chloroform, and acetone, and almost insoluble in water.

ACETUM, *P. G.*—Vinegar.

Vinaigre, Fr.; *Essig,* G.; *Aceto,* It.; *Vinagre,* Sp.

Vinegar is an aqueous liquid, containing acetic acid, obtained by the acetous fermentation of a hydro-alcoholic liquid, such as wine, cider, beer, etc. The wine, cider, beer, grain, etc., vinegars thus obtained differ, according to source, in taste, color, flavor, etc., these physical differences in turn being due to differences in chemical composition. Most vinegar is now prepared from grain, principally Indian corn, though cider and

wine vinegars may still be found in the market. The French Codex still calls for true white wine vinegar—in the United States this term is now generally applied to vinegar manufactured from grain spirit; the German and Swiss Pharmacopœias do not define any particular kind, grain vinegar evidently being implied; whereas the U. S. and Br. Pharmacopœias have substituted a diluted acetic acid of desired strength. Wood vinegar, even when rectified (see Acetum Pyrolignosum), should not be confounded with the above kinds, all of which are made by fermentation.

Preparation.—Vinegar was known to the ancients, and resulted wherever alcoholic beverages underwent acetous fermentation. This acetous fermentation can be brought about practically everywhere by simple exposure of such liquids, because the necessary germ, *Mycoderma aceti*, is well-nigh universal. The oxidation of the alcohol to acetic acid, according to the old (French?) process, is very slow, because the surface of the liquid exposed to oxygen, which is necessary to bring about oxidation, is relatively small. The process can be facilitated somewhat by careful selection of the wine, inoculation of the ferment, and regulation of temperature.

The quick vinegar process depends primarily upon providing a sufficiently large surface for the oxidation of the dilute alcohol. This is done by filling the fermentation casks with beech-wood shavings, which are tightly packed. After the shavings have been inoculated, as it were, by means of ready vinegar, the alcoholic liquid is poured over the shavings, either continuously by means of a hydraulic tourniquet or periodically. Frequently the partly oxidized liquid is poured over the shavings a second time. The change is controlled further by regulation of the temperature within the casks, and this in turn is regulated by the flow of air (oxygen) into them. The most favorable temperature is given at 27°–35° C. (80°–95° F.). The alcoholic material used for the quick process is either white wine, resulting in true white wine vinegar (*Vinaigre de vin blanc*, Fr.; *Weiss Wein Essig*, G.); cider, yielding cider vinegar (*Frucht Essig*, G.); beer, yielding beer vinegar (*Bier Essig*, G.); but mostly dilute spirits from grain, yielding grain vinegar (*Getreide Essig*, G.) or spirit vinegar (*Sprit Essig*, G.), also commonly, though falsely, designated commercially as "white wine vinegar," evidently because this kind has displaced almost universally the former true white wine vinegar.

Vinegar is a clear, almost colorless liquid, of sour odor and taste. Spirit vinegar frequently is colored to resemble cider or wine vinegar. After neutralization with sodium hydroxide, the addition of a few drops of ferric chloride solution produces a deep-red coloration, due to formation of ferric acetate; upon heating, basic ferric acetate is precipitated.

Tests.—The German Pharmacopœia requires that vinegar shall contain 6 per cent. of acetic acid, and that 10 Cc. shall be neutralized exactly by 10 Cc. of normal alkali solution. (The Swiss Pharmacopœia demands but 5 per cent. of acetic acid, while the French Codex requires 7–8 per cent.) If to 20 Cc. of vinegar be added 0.5 Cc. of a 5 per cent. barium nitrate solution and 1 Cc. of decinormal silver nitrate solution, a filtrate should be obtained which will not be affected by a further addition of the two test-solutions, showing limit of sulphates and chlorides. Hydrogen sulphide should have no effect on vinegar, showing the absence of heavy metals; and nitric acid may be detected by the appearance of a brown zone if 1 Cc. of ferrous sulphate solution be poured carefully on top of a mixture of 2 Cc. each of vinegar and sulphuric acid. Upon complete evaporation vinegar should not leave more than 0.5 per cent. of residue, free from sharp or bitter taste, and not yielding an alkaline ash.

Acetum Destillatum. *Acetum purum, Distilled or pure vinegar*, E.; *Vinaigre distillé*, Fr.; *Distillirter oder reiner Essig*, G.—Ordinary vinegar is distilled from glass retorts until about three-fourths of its volume has passed over. It is colorless, leaves no residue on evaporation, is not colored by excess of potassium hydroxide (showing absence of aldehyde), and is free from mineral acids. It is practically identical with diluted acetic acid, containing 6 per cent. of absolute acetic acid.

Action and Uses.—Vinegar is seldom used internally in this country as a medicine. In small doses it may increase the gastric secretions and stimulate the salivary glands to greater activity. In large amounts it disorders digestion and weakens the patient, and should not be used in the treatment of obesity. It has been recommended in the treatment of diarrhœa, dysentery, diphtheria, and lead colic, but in these conditions has little medicinal value. The drug, when inhaled, frequently relieves vomiting, especially that following the use of ether and chloroform, and is said to be useful in the early stages of coryza and headache.

As a lotion, 1 part in 4 of water, it is used in night-sweats, to arrest small hemorrhages, and as a cooling application to sprains and discolorations of the skin due to injury. Rectal injections of vinegar are said to be useful in the removal of ascarides.

Poisonous amounts of vinegar produce nausea and vomiting, purging, and violent pain in the stomach and intestines. Later, symptoms of collapse may occur, the skin becoming cold and clammy, the temperature subnormal, and the circulation and respiration impaired. The treatment of poisoning by vinegar consists in giving large quantities of milk and mild alkaline drinks, as lime-water or solutions of soap. If symptoms of collapse are present, resort to stimulation with alcohol, strychnine, or belladonna, and apply external heat. Morphine may be given to relieve the pain. Dose, 1 to 4 drachms (4–16 Cc.).

Acetum Antisepticum, Fr. Cod.; *Antiseptic vinegar,* E.; *Vinaigre (Acétolé) antiseptique, Vinaigre des quatre voleurs,* Fr.; *Vierraeuberessig,* G.—Absinthe, Roman wormwood, peppermint, rosemary, rue, sage, and lavender, of each, 15 Gm.; calamus, cinnamon, cloves, nutmeg, and garlic, of each, 2 Gm.; vinegar, 1000 Gm.; macerate for 10 days, express, add 4 Gm. of camphor dissolved in 15 Gm. of glacial acetic acid, and filter. The *Aceto antisettico* of the Italian Pharmacopœia contains camphor and orange leaves.

Acetum Pyrolignosum Crudum, P. G.—*Wood vinegar. Pyroligneous acid,* E.; *Acide acétique du bois, A. pyroacétique, A. pyroligneux,* Fr.; *Roher Holzessig, Rohe Holzsäure, Rohe Holzessigsäure,* G.—Upon destructive distillation, wood yields a gaseous and a liquid distillate. The latter, upon standing, separates into two layers, an aqueous layer, and an oily or tarry layer known as wood-tar. The yield of aqueous distillate, tar, and charcoal does not differ greatly with different kinds of wood, but the percentage of acetic acid in the aqueous distillates varies considerably according to the nature of the wood. Hard wood yields more than that of coniferous trees; the wood of the trunk more than that of the branches, sound wood more than diseased wood or bark. The two principal constituents of the aqueous distillate are methyl alcohol and acetic acid. The former is separated by removing about one-tenth of the liquid by fractional distillation (see Wood Alcohol). The remaining nine-tenths are brought into the market as such, or after the removal, by distillation, of most of the tar, retained in solution as crude pyroligneous acid. The principal constituent is acetic acid, of which it contains from 10 to 13 per cent. (from hard wood) or only 5 to 7 per cent. (from pine). In addition it contains small amounts of the homologous acids up to 6 C-atoms. Of the numerous other products formed by the destructive distillation of wood, small amounts are contained in crude pyroligneous acid—*e. g.*, methyl alcohol, acetone, valerolactone, tetramethylene ketone, methyl pentamethylene ketone, methyl acetate, furfurol, pyromucic acid, pyridine, also numerous constituents of the wood-tar, notably phenols (see Wood-tar). To the presence of the latter are due the brown color and empyreumatic odor, also in large part the antiseptic properties of the crude pyroligneous acid. The German Pharmacopœia describes crude pyroligneous acid as follows: "A brown liquid, having the odor of tar and acetic acid, and possessing an acid, bitter taste, from which tarry substances separate upon standing. It should contain at least 6 per cent. of acetic acid, and 10 Cc. of wood vinegar should not react alkaline after the addition of 10 Cc. normal potassium hydroxide solution. Wood vinegar diluted with an equal volume of water should not be affected by hydrogen sulphide (absence of heavy metals), nor be colored more than light blue by potassium ferrocyanide solution (limit of iron), or become more than opalescent upon addition of either barium nitrate or silver nitrate solutions (limit of hydrochloric and sulphuric acids).

Acetum Pyrolignosum Rectificatum, P. G., Fr.—*Rectified wood vinegar. Rectified pyroligneous acid,* E.; *Acide pyroligneux purifiée,* Fr.; *Gereinigter oder rectificirter Holzessig,* G.—Rectified wood vinegar differs from the crude principally in its lesser percentage of tarry constituents. It can be prepared by distillation of the crude product, collecting 8 parts of distillate from 10 parts. The P. G. describes it as follows: A yellowish liquid having an empyreumatic, sour odor and taste, and containing at least 5 per cent. of acetic acid. Impurities may be detected as indicated under the head of the crude acid. If to 20 Cc. of potassium permanganate solution, a mixture of 1 Cc. of rectified wood vinegar, 9 Cc. of water, and 30 Cc. of dilute sulphuric acid be added, the red color should be destroyed completely within 5 minutes (distinction from diluted acetic acid). 10 Cc. of rectified wood vinegar should require not less than 8.4 Cc. and not more than 9 Cc. of normal alkali solution for neutralization. The French name *Acide pyroligneux purifiée* is retained merely as a synonym for *Acide acétique du commerce* or commercial acetic acid, containing 50 per cent. of $C_2H_4O_2$.

ACETUM AROMATICUM, *P. G.*—Aromatic Vinegar.

Aromatischer Essig, G.; *Vinaigre (Acétolé) aromatique,* Fr.

Preparation.—Take of volatile oils of cassia, juniper, lavender, peppermint, and rosemary, of each, 1 part; eugenol and oil of lemon, of each, .2 parts; alcohol (91 per cent.), 441 parts; acetic acid (30 per cent.), 650 parts; water, 1900 parts. Dissolve the oils in the alcohol, add the acid and water, set the turbid mixture aside, with frequent agitation for 8 days, and filter.—P. G.

It is a clear, colorless liquid, of an aromatic, acetous odor, miscible with water in all proportions without becoming turbid. The corresponding preparation of the French Codex is made from a tincture of fresh herbs, and has a pale-reddish color.

The Austrian Pharmacopœia directs aromatic vinegar to be prepared from peppermint, rosemary, and sage, of each, 25 parts; angelica, zedoary, and cloves, of each, 2 parts; vinegar, 1000 parts.

Action and Uses.—Aromatic vinegar is sometimes used as a cooling lotion or an inhalant in cases of headache.

ACETUM CANTHARIDIS, *Br.*—Vinegar of Cantharides.

Vinaigre cantharidé, Fr.; *Canthariden essig*, G.

Preparation.—The British Pharmacopœia directs that 2 ounces (or 100 Gm.) of bruised cantharides be macerated for 24 hours in 18 fluidounces (or 900 Cc.) of a mixture of equal volumes of glacial acetic acid and distilled water. The whole is then transferred to a percolator, and when the liquid ceases to pass, sufficient of the above menstruum is poured over the contents of the percolator to produce 1 Imperial pint (or 1000 Cc.) of percolate.

Action and Uses.—Vinegar of cantharides is employed externally as a vesicant, and if lightly applied as a rubefacient. Because of the softening power and penetrability of acetic acid, it is more rapid in its action than any other preparation of the drug. It may be used upon those portions of the body where the ordinary cerate cannot be kept in place, but should be applied over only a very limited area, on account of the danger of absorption. Its application is more painful than that of the other preparations of cantharides.

ACETUM IPECACUANHÆ, *Br.*—Vinegar of Ipecac.

Vinaigre d'ipecacuanha, Fr.; *Brechwurzelessig*, G.

Preparation.—The British Pharmacopœia directs a mixture to be made of liquid extract of ipecac, 1 fluidounce (or 50 Cc.); 90 per cent. alcohol, 2 fluidounces (or 100 Cc.); and diluted acetic acid (4.27 per cent.), 17 fluidounces (or 850 Cc.). The mixture is filtered, and if necessary sufficient diluted acetic acid is added to the filtrate to make 1 Imperial pint (or 1000 Cc.).

As the liquid extract of ipecac of the British Pharmacopœia is standardized to contain 2–2.25 Gm. of alkaloids in every 100 Cc., the above vinegar will represent about $\frac{1}{15}$ grain of the alkaloids of ipecac in each teaspoonful, or 0.00106 Gm. in each Cc.

Action and Uses.—Vinegar of ipecac is a useful expectorant in the early stages of acute bronchitis. On account of the irritant effect of acetic acid upon the mucous membranes, it should not be given in doses sufficiently large to produce emesis. The dose is stated to be from 5 to 40 minims (0.3–2.6 Cc.).

ACETUM OPII, *U. S.*—Vinegar of Opium.

Black drop, E.; *Vinaigre d'opium*, Fr.; *Opiumessig*, G.

Preparation.—The Pharmacopœia directs that 100 Gm. of powdered opium and 30 Gm. of nutmeg in No. 30 powder be macerated with 500 Cc. of diluted acetic acid during 7 days, with frequent agitation; the mixture is then strained through muslin of close texture and the liquid expressed. The residue is mixed with 200 Cc. of diluted acetic acid to a uniform magma, and again strained and expressed. The strained liquids are mixed and filtered, and 200 Gm. of sugar dissolved in the filtrate, sufficient diluted acetic acid being passed through the filter to bring the total volume up to 1000 Cc.

To prepare a pint of vinegar of opium will require 730 grains of powdered opium, 220 grains of nutmeg, 1460 grains of sugar, and a sufficient quantity of diluted acetic acid.

Vinegar of opium is of a reddish-brown color and rather pleasant, acetous odor. It is of the same morphine strength as tincture of opium (0.012–0.0125 Gm. in 1 Cc.), and may be assayed by the method given under the latter preparation, except that the acid present is neutralized first by addition of calcium carbonate (4–5 Gm. to 100 Cc.).

Action and Uses.—Vinegar of opium is used as an anodyne and hypnotic. As it contains no narcotine, it is not so liable to produce depression and nauseating after-effects

as the other preparations of the drug, with the exception of the tincture of deodorized opium, which is also free from the above-mentioned alkaloid. Vinegar of opium is usually given in the dose of from 5 to 20 minims (0.3–1.30 Cc.).

ACETUM SCILLÆ, *U. S., Br., P. G.*—Vinegar of Squill.

Acetum scilliticum.—*Vinaigre* (*Acétolé*) *de scille*, Fr. Cod.; *Meerzwiebelessig*, G.; *Aceto scillitico* F. It.

Preparation.—The U. S. Pharmacopœia directs that 100 Gm. of squill in No. 20 powder be macerated with 900 Cc. of diluted acetic acid during 7 days, with frequent stirring, then strained through muslin and the mass washed on the strainer with sufficient diluted acetic acid to obtain about 1000 Cc. Heat this liquid to boiling, filter while hot, and when cooled add sufficient diluted acetic acid to make the product measure 1000 Cc.

To prepare 1 pint of official vinegar of squill, macerate 722 grains of squill with 14 fluidounces of diluted acetic acid for 7 days, and after expression wash the residue with sufficient menstruum to obtain a total volume of 16 fluidounces.

The British Pharmacopœia orders 2½ ounces (or 125 Gm.) of bruised squill to be macerated for 7 days with 1 Imperial pint (or 1000 Cc.) of diluted acetic acid, then strained and filtered.

According to the German Pharmacopœia, 5 parts of squill, cut and dried, are to be macerated with 5 parts of alcohol, 9 parts of acetic acid (30 per cent.), and 36 parts of water for 3 days, at a temperature of 15°–20° C. (59°–68° F.); the mixture is then strained without forcible expression, and after 24 hours filtered.

Vinegar of squill is a clear liquid of yellowish color, an acetous odor, and an acid, bitter taste.

Action and Uses.—Vinegar of squill is at present rarely employed in medicine. It is recommended as a stimulant or irritant diuretic in chronic nephritis, and in renal congestion resulting from cardiac disease. It is stated that the preparation possesses some value in the treatment of pericardial, pleural, and abdominal effusions, but other more satisfactory remedies usually are given. It is rarely used at present in cardiac dropsy. Its average dose is 15 minims (1 Cc.), best administered in an aromatic draught.

ACETYLENUM.—Acetylene.

Ethine, E.; *Acetylen, Aethin, Steingas*, G.

Formula, C_2H_2. Molecular weight, 25.82.

History and Formation.—The name acetylene was first given to this hydrocarbon in 1860 by Berthelot, although the gas had been discovered by Edmund Davy in 1830 in an attempt to prepare potassium by the action of water on a mixture resulting from heating carbonized tartar and charcoal. Davy called the new hydrocarbon *klumene*. Berthelot obtained acetylene by passing the vapors of alcohol, wood alcohol, ether, etc., through a red-hot tube, and also observed its presence in illuminating-gas. He prepared it synthetically by passing a powerful electric current between two carbon poles in an atmosphere of hydrogen. Acetylene is the only hydrocarbon capable of production by direct union of its constituent elements. For a long time it was prepared by the action of potassium hydroxide on ethylene bromide, but of late years, since acetylene has come extensively into use as an illuminating agent, it is made by the action of water on calcium carbide in suitable apparatus, the following decomposition occurring: $CaC_2 + 2H_2O = C_2H_2 + Ca(OH)_2$.

Properties.—Acetylene is a colorless gas of unpleasant odor. It is about nine-tenths as heavy as air, and can be liquefied under a pressure of 21.5 atmospheres. Liquid acetylene boils at —83° C. (—117.4° F.), and 1 kilogramme of the fluid corresponds to 858 liters of gaseous acetylene at 0° C. (32° F.). Acetylene is soluble in an equal volume of water, and more soluble in alcohol and in ether. It is insoluble in concentrated brine. If pure acetylene be ignited, it burns with a very smoky flame; but if mixed with air in the proportion of 2 volumes of the latter to every 3 volumes of acetylene, the mixture will burn, from a suitable burner having a fine slit, with a dazzling white flame free from smoke. Mixtures of acetylene and air in various proportions explode if ignited; the most explosive being a mixture of 1 volume of acetylene and 12 volumes of air. The range of explosiveness lies between mixtures of 3 volumes of

acetylene with 97 volumes of air and 81 volumes of acetylene with 19 volumes of air. While acetylene is poisonous, it is far less so than illuminating-gas, and animals have been known to live in an atmosphere containing 9 per cent. of acetylene, without unpleasant effects. It does not appear to cause any change in the hæmoglobin of the blood, as was formerly supposed to be the case.

Acetylene prepared from commercial calcium carbide may contain from 1 to 3 per cent. of impurities, consisting of hydrogen phosphide, carbon disulphide, ammonia, carbon monoxide, etc. For purposes of purification the gas is first passed through water for the removal of ammonia, and next over moist chlorinated lime, whereby any hydrogen phosphide present is oxidized to phosphoric acid; it is then passed over copper sulphate or ferric hydroxide to remove carbon disulphide, and finally dried by passing over freshly burned lime.

Action and Uses.—Acetylene is said to possess narcotic properties, but its depressing action upon the heart prevents its employment in medicine. Maisson and Etheridge have employed suppositories of calcium carbide in the cavity of the uterus in the treatment of uterine cancer. Acetylene is given off from this substance in the presence of moisture, and it is claimed that its action has proved quite successful in advanced cases. Its application is painful for the first 3 or 4 hours, after which time little inconvenience is experienced. It is probable that the application of this substance possesses no distinct advantage over the thermocautery. The calcium carbide is introduced, and this is followed by a tight packing of iodoform gauze, which is allowed to remain 3 days. This is repeated every third day for a period of several months. Acetylene destroys the odor, materially decreases the discharge and hemorrhage, and in some cases is supposed to have produced a cure.

ACIDA.—Acids.

The term acid (from *acere*, to be sour) was given early in the history of chemistry to substances that had a sour taste. One of the earliest known of such substances was vinegar, the Latin name of which, *acetum*, indicates its sour property, as does also the word *acetic*, which is the name given to the acid in vinegar.

Another general property of acids is the power to change the color of certain dyes, as litmus, for example. Litmus is naturally blue, but when brought into a solution containing an acid it changes to red.

But neither of these properties is essential in order that a substance be classed as an acid, for there are some acids which are neither sour nor have the power to change the color of dyes. As a rule these acids are insoluble in water, and are termed *weak* acids. In general, acids which are soluble in water have a markedly sour taste and a reaction on dyes, such as litmus.

Another property which is strictly chemical and more important in determining whether a body is an acid, is the liberation of hydrogen gas when it is brought in contact with certain metals, as zinc, or more especially magnesium. Coördinate with this is also the power to combine with such substances as caustic soda or caustic potash, which are called *alkalies*. In both cases new and distinct compounds are formed, with properties quite different from those of the acid.

The liberation of hydrogen by magnesium leads to the general chemical definition of an acid, namely, An *acid* is a substance containing hydrogen, which it easily exchanges for a metal when treated with a metal itself, or with a compound of a metal, called a base or hydroxide.

A *base* or basic substance is a *metal* in combination with hydrogen and oxygen—that is, with the water residue (OH) known as *hydroxyl*. They are hence called hydroxides. The most striking and typical examples of bases are potassium and sodium hydroxides, KOH and NaOH, which bear the specific name *alkali*. (A few substances, chiefly ammonium hydroxide and its derivatives, have basic properties, but contain no metal.)

Bases are opposite in properties to acids, inasmuch as they in general restore the blue color of litmus that has been reddened by acids, and also destroy or *neutralize* the properties of acids.

The action of metals and bases on an acid is illustrated by the following equations: (1) $Zn + H_2SO_4 = ZnSO_4 + H_2$; (2) $Mg + H_2SO_4 = MgSO_4 + H_2$; (3) $Zn(OH)_2 + H_2SO_4 = ZnSO_4 + H_2O$; (4) $Mg(OH)_2 = H_2SO_4 = MgSO_4 + H_2O$; (5) $2KOH + H_2SO_4 = K_2SO_4 + H_2O$; (6) $NaOH + HCl = NaCl + H_2O$. Zinc and magnesium,

and their hydroxides, are represented in reaction with sulphuric acid, forming zinc and magnesium sulphates, with the liberation of hydrogen in the one case (metals) and water in the other. The metal has exchanged places with the hydrogen of the acid, forming a new body, which is called a *salt.* Salts are in general neutral compounds, possessing neither the properties of the metals nor of the acids which enter into them. A constant product in the formation of salts by neutralization of an acid by a base is water, as shown in equations 3, 4, 5, and 6.

Hydrogen is the acidifying element in all acids, but it was believed by Lavoisier and his followers, about the close of the eighteenth century, that oxygen caused the acid properties, which fact is indicated in the name Lavoisier gave to this element, namely, *oxygen,* which means acid-forming. This view arose from the fact that many oxides when dissolved in water gave acid solutions, and hence the oxides themselves were regarded as acids. Now such oxides are called *acidic oxides* or *acid anhydrides;* that is, acid minus water; thus, $SO_3 = H_2SO_4 - H_2O$. It has been proved that such oxides when perfectly free from water have no acid properties.

Custom perpetuates the error of the earlier chemists in the case of a few anhydrides which at the present day are called acids, and no doubt will continue thus to be designated for some time to come. Thus, CO_2, As_2O_3, CrO_3, SiO_2, SnO_2, OsO_4, are called, respectively, carbonic, arsenous, chromic, silicic, stannic, and osmic acid. The acids of these oxides are unstable, and cannot be obtained in the free state, but exist only in solution. Thus when we attempt to liberate carbonic acid from a carbonate by addition of sulphuric acid, we get the oxide CO_2, for the acid breaks up at once into water and the anhydride, $H_2CO_3 = H_2O + CO_2$.

While the great majority of acids contain oxygen, and are in reality a combination of the acid anhydrides with water, there are some well-marked acids which contain no oxygen; for example, the halogen acids, hydrobromic, hydrochloric, etc., HBr., HCl.

In the oxygen acids the replaceable hydrogen is in combination with oxygen as (OH), or hydroxyl, but the formulas usually employed, namely, the empirical or molecular, do not represent this fact. Thus we usually write for nitric acid HNO_3, but the more exact representation is NO_2OH.

Basicity of Acids.—According to the number of replaceable hydrogen atoms in acids, they are designated as *monobasic, dibasic, tribasic,* etc., acids. The terms refer to the number of molecules of a base containing a univalent metal that are required to neutralize fully an acid. Examples of monobasic acids are HCl, HBr, HI, HF, HNO_3, HPH_2O_2, $HC_2H_3O_2$, etc.; dibasic acids, H_2SO_4, H_2SO_3, H_2CO_3; tribasic acids, H_3PO_4, H_3BO_3, etc.

Some text-books distinguish between the replaceable and the non-replaceable hydrogen atoms by writing the former at the beginning of the formulas. Thus, hypophosphorous acid, HPH_2O_2; acetic acid, $HC_2H_3O_2$; tartaric acid, $H_2C_4H_4O_6$; citric acid, $H_3C_6H_5O_7$.

Acids containing more than one replaceable hydrogen atom can form more than one salt, according as one, two, three, etc., hydrogen atoms are replaced by metal. When all the acid hydrogen is replaced by metal the salt is termed *normal.*

Dibasic acids form two classes of salts, normal and *acid* or *bi-salts;* thus, Na_2SO_4, *acid* sodium sulphate or sodium *bi*sulphate.

Tribasic acids form three classes of salts, termed *mono-, di-,* and *tri-,* or *primary, secondary,* and *tertiary,* according as one, two, or three hydrogen atoms have been replaced by metal. The best illustration is offered by phosphoric acid, H_3PO_4:

H_2NaPO_4 = mono- or primary sodium phosphate.
HNa_2PO_4 = di- or secondary sodium phosphate.
Na_3PO_4 = tri- or tertiary (or normal) sodium phosphate.

The first two are also acid salts.

Bases which can neutralize more than one acid hydrogen atom give rise to several salts, designated *normal* and *basic.* The basic salts are those in which the base is not combined with all the acid it is capable of saturating. Thus, bismuth hydroxide, $Bi(OH)_3$, can form three nitrates, $Bi(OH)_2NO_3$, $Bi(OH)(NO_3)_2$, and $Bi(NO_3)_3$. The first two are basic salts.

Derived Acids.—Some acids are capable of splitting off water from one or more molecules by the aid of heat or otherwise, and forming related acids. This is well illustrated in the case of phosphoric and boric acids. When the former is gradually

heated to low red heat, the first change is the formation of pyrophosphoric acid by the elimination of 1 molecule of water between 2 molecules of acid; thus, $2H_3PO_4 = H_4P_2O_7$ (pyrophosphoric acid) $+ H_2O$. The next change is the formation of metaphosphoric acid by the further elimination of another molecule of water; thus, $H_4P_2O_7 = 2HPO_3$ (metaphosphoric acid) $+ H_2O$. Arsenic acid behaves in the same manner.

Boric acid when heated forms pyroboric and metaboric acids, $H_2B_4O_7$ and HBO_2. The most stable alkali borates are the salts of pyroboric or tetraboric acid.

Some acids, when heated sufficiently, lose all their hydrogen in the form of water, and leave behind the anhydrides; thus, arsenic acid leaves the pentoxide, As_2O_5, differing in this respect from phosphoric acid, which forms metaphosphoric acid as the last product.

INORGANIC ACIDS.

In this division are embraced all those acids which do not contain carbon, except carbonic acid, and perhaps hydrocyanic, HCN, cyanic, HOCN, sulphocyanic, HSCN, hydroferrocyanic, $H_4Fe(CN)_6$, and fulminic, acid, $H_2O_2C_2N_2$. The acids mentioned, although containing carbon, have properties so much like those of the other inorganic acids that they are grouped almost invariably with the latter. The great majority of inorganic acids are compounds of hydrogen, or of hydrogen and oxygen, with non-metallic elements. The exceptions to this statement are the acids of arsenic, antimony, chromium, molybdenum, manganese, and a few other metallic elements, and the acids mentioned above containing the group or radical (CN) cyanogen. The inorganic acids are gaseous, liquid, or solid. They are usually met with in commerce as dilute or concentrated aqueous solutions. Such non-official acids are described here as are considered to be of interest in one way or another, while the official acids will receive detailed treatment in alphabetical order farther on.

Acidum Arsenicum. *Arsenic acid. Acide arsénique*, Fr. Cod.; *Arsensäure*, G. $H_3AsO_4 + \frac{1}{2}H_2O$.—Obtained by oxidation of arsenous acid with nitric acid of specific gravity 1.38, evaporating to dryness to remove nitric acid, adding water, and evaporating again to dryness or to syrupy consistence. On neutralizing a sample with sodium hydroxide and adding a few drops of potassium dichromate solution, no green color should appear, showing the absence of arsenous acid. The acid is tribasic, crystallizing in plates or prisms. It occurs on the market as a white crumbly mass or coarse white powder which is hygroscopic. When strongly heated, it yields oxygen and arsenous acid. It is easily soluble in water, alcohol, and glycerin. With magnesia mixture and molybdate solution it acts like phosphoric acid (which see). For other tests, see under Arsenous Acid. The acid is not used medicinally, but the sodium salt is official. The acid is poisonous.

Acidum Cacodylicum. *Cacodylic acid, Dimethylarsenic acid*, E.; *Kakodylsäure*, G. $(CH_3)_2AsO.OH$.—This acid is related closely to arsenic acid, being a dimethyl derivative, as shown by the formula. When arsenous acid and potassium acetate are distilled together, an oil with a disgusting odor is obtained, which is known as Cadet's Liquid. This contains a little *cacodyl*. $As_2(CH_3)_4$, and much *cacodyl oxide*, $As_2(CH_3)_4O$, both oily liquids. The word cacodyl is derived from *κακώδης*, stinking. When treated with mercuric oxide, both oils are oxidized gradually to cacodylic acid. The acid forms odorless prisms, easily soluble in water. With lime-water the acid or its salts should yield no precipitate, proving the absence of oxalates, arsenites, and arsenate. Silver nitrate or magnesia mixture should give no precipitate. The acid is monobasic. The sodium and calcium salts have been introduced into medicine in the treatment of skin diseases and others. It is claimed that the acid and its salts are free from toxicity. Sodium cacodylate, $(CH_3)_2AsOONa$, a white soluble compound, is employed mostly, and is given hypodermically or internally in pills. Other cacodylates that have been experimented with are those of potassium, magnesium, lithium, quinine, iron, guaiacol, mercury. (E. Merck, *Annual Report*, 8, p. 51; *Pharm. Review*, 1901, xix. No. 8.)

Acidum Hydrofluoricum. *Hydrofluoric acid*, E.; *Acide fluorhydrique, Acide phtorique*, Fr.; *Fluorwasserstoffsäure, Flusssäure*, G. HF.—Fluorine exists in nature in combination with calcium as *fluor-spar*, also in *cryolite* (kryolite) and other minerals; small quantities of fluorine have been found in some mineral and potable waters, in bones, and in the ashes of various plants. The use of fluor-spar for etching on glass was known to Schwaukhard (1670), but hydrofluoric acid was discovered by Scheele (1771), and first prepared pure by Gay-Lussac and Thénard (1808). *Preparation.*—Powdered fluor-spar (or cryolite) which is free from silica is heated with sulphuric acid in a retort of platinum or lead, and the gas is conducted into distilled water contained in a well-cooled receiver of the same metal. Great caution is necessary to prevent contact with the vapors and to avoid inhaling them. *Properties.*—Pure hydrofluoric acid forms a thin colorless fuming liquid which is lighter than water, solidifies at —92.5° C. (—134.6° F.), boils at 19.4° C. (67° F.), and is freely soluble in water. The aqueous solution, which sometimes is called *fluoric acid, acide fluorique*, is heavier than water; a solution having the density 1.15 contains 35.37 per cent. of HF, and boils constantly at 120° C. (248° F.) (Bineau). Like

the pure acid, it is extremely caustic, and causes severe ulceration when applied to the skin. It corrodes glass and attacks most organic and inorganic compounds, but does not act upon paraffin; it is best preserved in bottles made of lead, gutta-percha, or hard paraffin. *Impurities.*—10 Cc. evaporated in a platinum dish should leave no residue. The acid diluted with water and acidified with hydrochloric acid should not give a precipitate with barium chloride solution (absence of sulphuric acid). Neither hydrogen sulphide nor ammonium sulphide, after neutralization, should give a precipitate (absence of arsenic, iron, lead, and zinc). The acid is purified by distillation from a platinum retort after standing some hours in contact with precipitated manganese dioxide. The strength of the acid may be determined by titration with normal alkali (phenolphtalein indicator) in beakers coated with paraffin. Each Cc. of alkali is equivalent to 0.02 Gm. of HF. While fluorine, chlorine, bromine, and iodine belong to the same natural family, the *halogens*, the fluorides differ in many respects from the chlorides, bromides, and iodides. For example, AgF is soluble in water, while AgCl, AgBr, and AgI are insoluble in water and acids. CaF_2 is quite insoluble in water, while $CaCl_2$, $CaBr_2$, and CaI_2 are deliquescent and very soluble. *Uses.*—Hydrofluoric acid in the gaseous state and its aqueous solution are used for etching on glass. *Ammonium fluoride* has a similar effect; it forms white or colorless scales or prisms, which are deliquescent and should be kept in a gutta-percha bottle. According to F. L. Slocum (1880), a mixture suitable for writing on glass, like that sold at one time as *diamond ink*, is made by mixing barium sulphate 3 parts, ammonium fluoride 1 part, and sulphuric acid sufficient to form a semifluid mixture; if kept in glass, this should be coated on the inside with paraffin, wax, or gutta-percha. The free acid, as well as the ammonium salt, is used to decompose silicates for analysis. The acid is added to the mash in the manufacture of spirits, to prevent lactic acid fermentation. The element fluorine was isolated by H. Moissan (1886) by electrolysis of anhydrous HF in platinum. It is a greenish-yellow gas, lighter in color than chlorine, with similar but more intense chemical activity. Of metals, only gold and platinum are not attacked by fluorine at ordinary temperature. It is the most active element. Oxygen, nitrogen, chlorine, and argon, however, are indifferent toward it. In 1900 Moissan observed that fluorine may be prepared in copper vessels at low temperatures, as the copper is soon coated with a film of insoluble fluoride, which protects it. *Action and Uses.*—Hydrofluoric acid is at present practically never used in medicine. In the strength of a 1 : 2500 solution in water it has been recommended for the prevention of putrefaction and fermentation changes in food-products. Inhalations of the acid largely diluted with air were at one time employed in the treatment of pulmonary tuberculosis, but at present are not in vogue. The fluorides are no longer used, because of the gastric disorder which they occasion.

Acidum Hydrosilicofluoricum. *Hydrofluosilicic acid*, E.; *Kieselfluorwasserstoffsäure, Kieselflusssäure*, G. H_2SiF_6.—Prepared by the action of gaseous silicon tetrafluoride on water: $3SiF_4 + 4H_2O = 2H_2SiF_6 + Si(OH)_4$. SiF_4 is formed by the action of sulphuric acid on a mixture of calcium fluoride and sand (SiO_2): $4HF + SiO_2 = SiF_4 + 2H_2O$. The aqueous solution of the acid is colorless, volatile without residue when heated in a platinum dish, and attacks glass only moderately. It is a strong dibasic acid, used in chemical analysis to precipitate and separate barium from strontium, the barium salt being insoluble.

Acidum Iodicum. *Iodic acid*, E.; *Iodsäure*, G. HIO_3.—Prepared by oxidation of iodine (10 parts) with nitric acid of specific gravity 1.5 (50 parts). Warm until the iodine disappears and red vapors cease to come off. Evaporate to dryness, and heat 1 hour at 200° C. (392° F.) to drive off all nitric acid. Dissolve in water and evaporate again on a water-bath. Iodic acid forms colorless rhombic crystals, soluble in 1 part of water, less soluble in alcohol. At 170° C. (338.9° F.) it breaks up into water and the anhydride I_2O_5, which decomposes at 300° C. (572° F.) into iodine and oxygen. Reducing agents liberate iodine from the acid. The acid and its salts find use as chemical reagents. It is used also in medicine as a substitute for potassium iodide. It is employed in chronic glandular enlargements and goitre as an injection in the dose of ½ drachm (2 Gm.) of a 2 per cent. solution. Various salts of the acid are in use.

Acidum Molybdicum. *Molybdic acid, Molybdenum trioxide, Molybdic anhydride*, E.; *Molybdänsäure*, G. MoO_3.—Molybdenum occurs in nature principally as the sulphide or molybdenite, MoS_2, and as lead molybdate or wulfenite, $PbMoO_4$, from which the acid (anhydride) MoO_3 is manufactured. Other oxides of the metal exist—for example, MoO, Mo_2O_3, MoO—but only the highest oxide, MoO_3, has acid properties, and is analogous to chromic acid, CrO_3. It is a whitish, crystalline, glistening powder, scarcely soluble in water, soluble in nitric or hydrochloric acid. In solution it is easily reduced, forming blue compounds. It is soluble in ammonia water and alkalies, forming molybdates, which are derived from the normal acid, H_2MoO_4, or poly-acids, as H_2MoO_4, $H_2Mo_3O_{10}$, etc. Molybdates of other metals are insoluble. The ammonium salt is the most important, and is used as a delicate test for phosphoric acid (see Acidum Phosporicum), also in alkaloidal testing. When this salt is treated with nitrohydrochloric acid, the ammonia is destroyed, and on evaporation free *phosphomolybdic* acid crystallizes out, $H_3PO_4.10MoO_3.12H_2O$, which is used in tests and for the separation of alkaloids.

Acidum Nitrosum. *Nitrous acid*, E.; *Salpetrige Säure*, G. HNO_2.—This acid does not exist in the free state, but occurs in combination in salts known as nitrites, some of which are official. The nitrites can be formed by reduction of nitrates; for example, when KNO_3 is heated with lead: $KNO_3 + Pb = KNO_2 + PbO$. When nitrates are treated with a strong acid,

as sulphuric, the nitrous acid liberated at once decomposes into its anhydride and water: $2HNO_2 = N_2O_3 + H_2O$. In this respect the acid behaves like carbonic acid. Nitrites find use in organic chemistry in forming diazo from amido compounds and in preparing the official ethyl and amyl nitrites.

Acidum Osmicum s. Perosmicum. *Osmic acid, Osmium tetroxide,* E.; *Osmiumsäure,* G. OsO_4.—The metal osmium belongs to the platinum group, and occurs alloyed with the members of this group in a few localities. It is obtained in the free state by complicated processes. When finely divided osmium is heated to 400° C. (752° F.) in the presence of oxygen, it burns to the tetroxide, which is volatile, and is caught in a well-cooled receiver. This is usually called osmic acid, though its acid properties are very weak. It occurs in lustrous, transparent yellow acicular crystals, very hygroscopic, and with an unbearable penetrating odor (the vapor is poisonous). Its boiling-point is about 100° C. (212° F.), and it forms with water a colorless solution which has an intensely acrid and burning taste, and upon addition of sulphurous acid is colored yellow, then red, green and finally blue. Osmic acid liberates iodine from iodides, is reduced from its solution by silver and other metals, and oxidizes organic compounds. It has been employed internally in doses of $\frac{1}{65}$ grain (0.001 Gm.), and subcutaneously in the form of a 1 per cent. solution (which should be freshly prepared) in cases of neuralgia, goitre, cancroid and scrofulous ulcers, and also epilepsy. (See also Potassium Osmate.)

Acidium Phosphorosum. *Phosphorous acid,* E.; *Phosphorige Säure,* G. H_3PO_3.—Obtained by action of phosphorus trichloride, PCl_3, on water: $PCl_3 + 3H_2O = P(OH)_3 + 3HCl$. The solution is evaporated and heated on a sand-bath to 180° C. (356° F.), to drive out HCl, and the residue then dissolved in water. It consists, when free from water, of a colorless crystalline mass, melting at 74° C. (165.2° F.) and decomposing above 180° C. (356° F.) into PH_3 and H_3PO_4: $4H_3PO_3 = PH_3 + 3H_3PO_4$. Phosphorous acid reduces many compounds, as potassium permanganate, silver, gold, and mercury salts. It is a dibasic acid; the salts are called *phosphites.* It is used in analysis to reduce mercuric to mercurous chloride for quantitative determination.

Acidum Selenicum. *Selenic acid,* E.; *Selensäure,* G. H_2SeO_4.—Prepared by oxidizing silver selenite suspended in water with bromine. It resembles sulphuric acid very much. Hydrogen selenide, H_2Se, like H_2S, is a gas, which affects the mucous membranes and is more poisonous than hydrogen sulphide. According to Otto Rosenheim (*Chem. News,* 83, p. 277), the presence of selenium interferes with the tests for arsenic by the Marsh's and other methods. Under certain conditions the arsenic mirror is inhibited completely. Selenium may be detected in the presence of arsenic by the Reinsch test, by using first silver- instead of copper-foil to precipitate the selenium, after which the arsenic may be deposited on copper-foil. Selenium compounds may be recognized by giving an odor of radishes upon heating, and by yielding a red amorphous precipitate of selenium with reducing agents, such as sulphur dioxide.

Acidum Selenosum. *Selenous acid,* E.; *Selenige Säure,* G. H_2SeO_3.—Selenium belongs to the sulphur group of elements. It resembles sulphur very closely in its compounds, but occurs in nature nowhere in large quantities. It is found combined with lead, copper, silver, and thallium, in the sulphur of Volcano Island, and in certain pyrites, which explains the occasional occurrence of selenium in sulphuric acid. Selenium, like sulphur, is a solid existing in several allotropic modifications. When selenium is heated in dry oxygen, it burns with a bluish-green flame, forming the dioxide, which, unlike sulphur dioxide, exists as white needles, volatile at 300° C. (572° F.) without melting. This dissolves in water, forming the acid H_2SeO_3, which is much more stable than sulphurous acid. Mecke finds a solution of selenous acid 0.5 Gm. in concentrated sulphuric acid 100 Gm. to be a sensitive reagent for alkaloids (*Apoth. Ztg.,* Sept. 6, 1899).

Acidum Silicotungsticum. *Silicotungstic acid,* E.; *Kieselwolframsäure,* G. $12WO_3.SiO_2.2H_2O$.—Tungstic acid forms interesting and complex acids with other acids, notably silicic acid. Salts of the above acid which can be crystallized are obtained by boiling alkali paratungstate, $Na_{10}W_{12}O_{41}$, with precipitated gelatinous silicic acid. The sodium salt is soluble in one-fifth its weight of water, the solution having the remarkably high specific gravity 3.05. Gabriel Bertrand (*Compt. rend.,* 128, 742) has found the alkali salts of the acid to be excellent reagents for alkaloids, forming well-defined permanent salts, white or yellow in color, nearly insoluble in cold water, with the general formula $12WO_3.SiO_2.2H_2O.4Alkaloid + nH_2O$. The alkaloids are set free from these precipitates by alkalies and ammonia water.

Acidum Telluricum. *Telluric acid,* E.; *Tellursäure,* G. H_2TeO_4.—Tellurium is a rare element, occurring combined with gold, silver, lead, and bismuth. It belongs to the sulphur group of elements, but has metallic properties. It forms a hydride, H_2Te, and a dioxide, TeO_2. H_2Te is a very poisonous, colorless, badly smelling gas. TeO_2 is colorless, sublimable, and melts at a red heat. Telluric acid, H_2TeO_4, is difficultly soluble; its solution heated to 40° C. (104° F.) precipitates TeO_2. Telluric acid crystallizes as the normal hydrate $Te(OH)_6$ in prisms, soluble in water. On drying the crystals in a warm place, H_2TeO_4 is formed, which at 160° C. (320° F.) gives orange-yellow TeO_3 and water. The salts of telluric acid have little analogy with those of sulphuric acid. Soluble and especially volatile compounds of tellurium, like those of osmium, have marked physiological activity, causing affections of the nervous system, and especially of the eyes. They give a repulsive odor to the perspiration and the breath.

Acidum Vanadicum. *Vanadic acid,* E.; *Vanadinsäure,* G. H_3VO_4.—This is the most important and best known of the compounds of vanadium. It is the final product of the oxidation of vanadium, and bears to this element the same relation that phosphoric, arsenic, and antimonic acids bear to phosphorus, arsenic, and antimony. Similarly there are ortho-, meta-,

and pyro-vanadates, though the most stable salts are the metavanadates, MVO_3. The free metavanadic acid is known. It is a beautiful golden-yellow compound, which may be used as a substitute for gold bronze. Vanadic acid and its sodium salt have been recommended in the treatment of tuberculosis and rheumatism.

ORGANIC ACIDS.

Organic acids may be defined as carbon compounds having the carboxyl group, COOH, as a characteristic constituent. They combine, on the one hand, some of the properties of the carbonyl group, CO, which is found in aldehydes and ketones, and, on the other hand, those of the hydroxyl group, OH, which is characteristic of the alcohols and phenols. While this definition applies to all typical organic acids, other carbon compounds, not containing carboxyl, should also be classified as organic acids, because they possess certain properties found only in members of this class, such as an acid reaction and the ability to neutralize bases and form salts. In place of carboxyl, such acids may contain either the sulphonic group, HSO_3, as in the case of the benzene-sulphonic acids, or the phenol group, OH, as in the case of picric acid, or others.

Organic acids are derived from hydrocarbons of both the fatty and aromatic series, and may be divided into fatty and aromatic acids. The former may again be subdivided into acids of the methane series, olefine or ethylene series, acetylene series, etc., according to the saturation of the underlying hydrocarbons.

Like inorganic acids, the organic may be monobasic, dibasic, tribasic, tetrabasic, etc., depending, as in the case of the former, upon the number of replaceable hydrogen atoms in the acidifying groups. The replacement may be by metals or hydrocarbon radicals; if by the former, the resulting compound is called a salt, as in the case of potassium acetate, CH_3COOK; if by an alcohol radical, the compound is termed an ester, as in the case of ethyl acetate, $CH_3COOC_2H_5$; and if the hydrogen is replaced by an acid radical, an anhydride is formed, as acetic anhydride, CH_3COOCH_3CO. Polybasic organic acids are capable of forming normal as well as acid salts; thus, mono- and dipotassium tartrate, corresponding to mono- and dipotassium sulphate; mono-, di,- and trisodium citrate, corresponding to mono-, di-, and trisodium phosphate, etc. A few organic acids are also capable of forming salts by replacement of hydrogen in some other group besides the acidic carboxyl, as in the case of the diatomic monobasic salicylic acid and the triatomic dibasic meconic acid; these acids contain a hydroxyl group in which the additional replacement occurs, and the resulting salts have been termed *basic salts* by some authors.

Some organic acids are liquid at ordinary temperature, others are solid, and of the latter a few crystallize with definite proportions of water. They occur in nature both in a free state and in combination. Some are freely soluble in water and alcohol, others only to a limited extent, while others are insoluble in water, and a few also in cold alcohol.

Of the very large number of organic acids known to chemists, comparatively few only are of interest to physicians and pharmacists; some of these have been treated under separate headings on account of their greater importance, and the others will follow here in alphabetical order, without regard to their chemical relationship.

Acidum Aconiticum. *Aconitic acid*, E.; *Akonitsäure*, G. $H_3C_6H_3O_6$ or $CH_2CCH(COOH)_3$. —This tribasic acid exists in monk's hood, *Aconitum Napellus*, and other plants, and may also be obtained by dehydrating citric acid by heat or with concentrated hydrochloric or sulphuric acid. It occurs in small laminæ, very soluble in water, alcohol, and ether. It melts at 186.5° C. (376.7° F.), and decomposes at a higher temperature into carbon dioxide and pyrocitric acids.

Acidum Angelicum. *Angelic acid*, E.; *Angelikasäure*, G. $HC_5H_7O_2$ or $CH_3CH.CH.COOH$.—It occurs in the free state in angelica and sumbul roots and as amyl and butyl esters in the oil of anthemis. The acid may be obtained by boiling angelica root with milk of lime and distilling the filtered solution with sulphuric acid; the oily distillate upon cooling yields angelic acid in the form of shining prisms or needles, which melt at 45° C. (113° F.). It is readily soluble in hot water and alcohol, and volatilizes with the vapor of water.

Acidum Anisicum. *Anisic acid, Paramethoxybenzoic acid*, E.; *Anissäure*, G. $HC_8H_7O_3$ or $C_6H_4(OCH_3)COOH$.—This acid does not pre-exist in oil of anise, but is readily obtained therefrom by adding the same to a warm mixture of potassium dichromate, water, and sulphuric acid, whereby the anethol present is oxidized, being converted first into anisic aldehyde and finally to anisic acid. The crude acid which separates is purified by solution in ammonia water, precipitation with hydrochloric acid, and recrystallization from hot water. It occurs in colorless odorless monoclinic prisms or needles, which melt at 184° C. (373° F.), and are readily soluble in boiling water, alcohol, and ether, but only very sparingly in cold water. Its aqueous solution is acid to test-paper, but fails to show a violet coloration upon addition of

ferric chloride solution (difference from salicylic acid). Both sodium and phenyl anisate have been used in medicine; the latter compound has been erroneously called *anisophenylic acid.*

Acidum Arachicum. *Arachic acid, Arachidic acid,* E.; *Arachinsäure,* G. $HC_{20}H_{39}O_2$ or $C_{19}H_{39}COOH$.—A fatty acid found in the oil of the ground (pea or earth) nut, *Arachis hypogœa.* It may be obtained by saponification of the oil with an alkali and subsequent decomposition of the soap with hydrochloric acid. It crystallizes in small shining scales melting at 75° C. (167° F.), which are sparingly soluble in cold alcohol, but readily in ether and boiling alcohol.

Acidum Asparticum. *Aspartic acid, Amido-succinic acid,* E.; *Asparaginsäure, Amidobernsteinsäure,* G. $H_2C_4H_5NO_4$ or $C_2H_3NH_2(COOH)_2$.—This acid occurs in beet-molasses, and is produced by various reactions from albuminous substances. It may be obtained by boiling asparagin, found in asparagus and other plants, with alkalies or acids, and crystallizes in small rhombic prisms, moderately soluble in water. It unites both with acids and bases, and with the latter forms both normal and acid salts. By treatment with nitrous acid it is converted into malic acid.

Acidum Butyricum. *Butyric acid,* E.; *Buttersäure,* G.—Of this acid two modifications are known, namely, normal and isobutyric acids. The former, called also propyl-formic acid and ethyl-acetic acid, $HC_4H_7O_2$ or C_3H_7COOH, occurs in tamarinds and other plants, both free and in combination, but is chiefly of interest because occurring as a glyceride in animal and vegetable fats, especially cows' butter. It may be obtained by fermentation of sugar in contact with putrid cheese at a temperature of about 35° C. (95° F.) and over. Normal butyric acid is a colorless viscid liquid having an unpleasant odor, solidifying at —12° C. (8.4° F.) and boiling at 163° C. (325.4° F.). It dissolves readily in water and in alcohol. Ethyl butyrate, $C_3H_7CO_2C_2H_5$, is used in artificial pineapple flavor.

Isobutyric acid, or dimethyl-acetic acid, $HC_4H_7O_2$ or $HC(CH_3)_2COOH$, is found as a glyceride in croton oil and in a free state in St. John's bread, the fruit of *Ceratonia siliqua.* It resembles the normal acid, but has a less disagreeable odor and is not miscible with water.

Acidum Caffeicum. *Caffeic acid,* E.; *Kaffeesäure,* G. $HC_9H_7O_4$ or $C_6H_3(OH)_2.CH{:}CH.COOH$.—When caffeotannic acid is boiled with a solution of potassium hydroxide, caffeic acid is formed, and may be obtained by decomposing the resulting potassium salt. It crystallizes in yellowish prisms, very soluble in hot water and alcohol. The aqueous solution reduces silver nitrate when heated; ferric chloride colors it green, changing to dark red on addition of sodium carbonate.

Acidum Capricum. *Capric acid, Rutic acid,* E.; *Caprinsäure,* G. $HC_{10}H_{19}O_2$ or $CH_3(CH_2)_8COOH$.—This acid exists as a glyceride in the butter of cows' and goats' milk (hence its name, from *capra,* a goat), and also in cocoanut oil. It occurs as a colorless crystalline body, having a characteristic odor, which becomes stronger upon heating, and melts at 31.4° C. (88.5° F.). It is readily soluble in cold alcohol and ether, and dissolves without change in strong nitric acid.

Acidum Carbamicum. *Carbamic acid, Amido-formic acid,* E.; *Carbaminsäure,* G. HNH_2CO_2 or NH_2COOH.—This acid has never been obtained in the free state, but is of interest on account of its ammonium salt, $NH_2CO_2NH_4$, which enters into the composition of commercial ammonium carbonate and appears to be formed by direct union of ammonia gas and carbon dioxide. Ethyl carbamate, $NH_2CO_2C_2H_5$, has been used as a hypnotic under the name of *urethane.*

Acidum Ceroticum. *Cerotic acid,* E.; *Cerotinsäure,* G. $HC_{28}H_{53}O_2$ or $C_{27}H_{53}COOH$.—Cerotic acid exists in a free state in bees' wax, and may be extracted from the same by means of boiling alcohol. It crystallizes in small grains which melt at 78° C. (172.4° F.) and may be distilled without alteration. Its ceryl ester, $C_{27}H_{55}CO_2C_{27}H_{55}$, forms the chief constituent of Chinese wax, which is produced on certain trees in China by the puncture of a species of *coccus.*

Acidum Cinnamicum. *Cinnamic acid, Phenylacrylic acid,* E.; *Zimmtsäure,* G. $HC_9H_7O_2$ or $C_6H_5CH{:}CH.COOH$.—This acid occurs in Peru and Tolu balsams, storax, and in some varieties of benzoin, in oil of cinnamon as the result of oxidation of the cinnamic aldehyde. It may be obtained by boiling storax or powdered Tolu balsam with milk of lime, filtering and decomposing the resulting calcium cinnamate, which crystallizes out, with hydrochloric acid. It crystallizes in slender needles from hot water and in thick prisms from alcohol, which are inodorous and melt at 133° C. (271.4° F.). This acid dissolves readily in alcohol, but requires 3500 parts of cold water for solution. It is recognized by the odor of oil of bitter almond, benzaldehyde, developed if the acid be warmed with a solution of potassium permangate. Its sodium salt is hypodermically used in tuberculosis in the dose of $\frac{1}{6}$ to $\frac{1}{4}$ grain (0.001–0.015 Gm.).

Acidum Hippuricum. *Hippuric acid, Benzamidoacetic acid, Benzoyl glycocoll,* E.; *Hippursäure,* G. $HC_9H_8NO_3$ or $CH_2(NH.C_7H_5O).COOH$.—Hippuric acid occurs in the urine of horses and cattle, and is the form in which benzoic and cinnamic acids, toluene, and other aromatic substances are excreted when taken into the human organism. It may be obtained by boiling fresh urine of horses with milk of lime, filtering, concentrating the filtrate, and precipitating with hydrochloric acid; the crude acid is purified by washing with chlorine water. It crystallizes in rhombic prisms, with acid reaction and slightly bitter taste, which melt at 187° C. (368.6° F.), and are soluble in 600 parts of cold water, readily soluble in hot water and alcohol.

Acidum Lauricum. *Lauric acid,* E.; *Laurinsäure,* G. $HC_{12}H_{23}O_2$ or $CH_{11}H_{23}COOH$.—This acid occurs as a glyceride chiefly in the fruit of the bay tree, *Laurus nobilis,* of the spice

bush, *Lindera Benzoin*, and in pichury beans. It is associated also with other fatty acids in the oil of the cocoanut and other fruits, and may be obtained by saponifying these fats with alkali and decomposing the resulting soap with tartaric or hydrochloric acid. Lauric acid is insoluble in water, but is readily soluble in alcohol and ether, and crystallizes from alcohol in shining white silky needles, which melt at 43.6° C. (110.5° F.). The laurates of the alkali metals are soluble in water.

Acidum Malicum. *Malic acid, Hydroxysuccinic acid*, E.; *Aepfelsäure*, G. $H_2C_4H_4O_5$ or $C_2H_3OH(COOH)_2$.—Malic acid occurs both in the free and combined state in numerous fruits—hence its name from *malum*, apple—as well as the juice of garden rhubarb and of the berries of the mountain-ash, *Sorbus acuparia*. It is obtained by treating the neutralized expressed juice with lead acetate after removal of any oxalic acid present by calcium acetate, and collecting the resulting lead malate on a filter, washing, diffusing in water, and decomposing with hydrogen sulphide. The liquid is filtered, concentrated to a syrupy consistence, and left in a dry atmosphere until it becomes converted into a solid mass of malic acid. It crystallizes in groups of colorless prisms, somewhat deliquescent and readily soluble in water and in alcohol. If heated to 100° C. (212° F.), the acid melts, and at 140° C. (284° F.) it loses water and is converted into fumaric and maleic acids.

Acidum Mandelicum. *Acidum amygdalicum. Mandelic acid, Phenylglycollic acid*, E.; *Mandelsäure, Amygdalinsäure*, G. $HC_8H_7O_3$ or $C_6H_5.CHOH.COOH$.—This acid is of interest as forming with antipyrine a salt, antipyrine mandelate, known also as *tussol*, which is used to some extent in medicine. It may be prepared by heating the glucoside amygdalin with hydrochloric acid or by boiling oil of bitter almond (benzaldehyde) for 30 hours with hydrocyanic and hydrochloric acids; in the latter case benzyl oxycyanide, $C_6H_5CH(OH)CN$, is formed, which, taking up the elements of water, produces mandelic acid and ammonia. It crystallizes in prisms or plates, readily soluble in water, alcohol, and ether.

Acidum Meconicum. *Meconic acid, Oxychelidonic acid*, E.; *Mekonsäure*, G. $H_2C_7H_2O_7$ or $C_5HO_2(OH)(COOH)_2$.—Meconic acid occurs in opium, in which it was discovered first in 1805, and may be obtained by treating an infusion of opium with calcium chloride and chalk. The calcium meconate thus obtained is decomposed by hydrochloric acid, and the resulting crude meconic acid treated repeatedly with hydrochloric acid. It crystallizes in plates or prisms containing 3 molecules of water, readily soluble in alcohol and in hot water, but only sparingly in cold water. Ferric chloride added to solutions of meconic acid causes a blood-red color, due to formation of ferric meconate and closely resembling the color of ferric acetate and sulphocyanate, from which it can be distinguished, however, by its indifference to dilute hydrochloric acid (color of ferric acetate is discharged), and to auric and mercuric chlorides, which destroy the color of ferric sulphocyanate. This reaction may be used to determine the presence of opium in many liquids. Although meconic acid contains but two carboxyl groups, it contains three replaceable hydrogen atoms, of which one is derived from the hydroxyl group present, and is capable of forming acid, normal, and basic salts; the basic salts of the metals always have a yellow color. It was for a long time considered a tribasic acid, as announced by Liebig, but it has since been shown that only two carboxyl groups are present, and that hence it is only dibasic.

Acidum Myristicum. *Myristic acid*, E. *Myristinsäure*, G. $HC_{14}H_{27}O_2$ or $C_{13}H_{27}COOH$. —It occurs as glyceryl trimyristate in the fat of nutmegs, better known as nutmeg butter, and is found also in cocoanut oil and other fats. When pure it crystallizes in white shining laminæ which melt at 54° C. (129.2° F.), and are readily soluble in ether and in hot alcohol. The alkali myristates are soluble in water without decomposition—difference from the stearates.

Acidum Myronicum. *Myronic acid*, E.; *Myronsäure*, G. $HC_{10}H_{18}NS_2O_{10}$.—This acid occurs in black mustard seed as potassium myronate, a glucoside better known as *sinigrin*, upon which depends the production of volatile oil of mustard by reaction with an albuminous ferment called *myrosin*.

Acidum Opianicum. *Opianic acid, Aldehydodimethylprotocatechuic acid*, E.; *Opiansäure*, G. $HC_{10}H_9O_5$ or $C_6H_2(OCH_3)_2CHOCOOH$.—Opianic acid is of interest in pharmacy chiefly as a by-product in the manufacture of hydrastinine, by treating hydrastine with oxidizing agents. It is obtained also together with cotarnine when narcotine is subjected to oxidation. It occurs in slender colorless prisms, slightly soluble in cold water and melting at 140° C. (285° F.).

Acidum Palmiticum. *Palmitic acid, Hexadecylic acid*, E.; *Palmitinsäure*, G. $HC_{16}H_{31}O_2$ or $CH_3(CH_2)_{14}COOH$.—Palmitic acid occurs in nature in a free state and in combination. Solid animal fats are composed chiefly of the glyceryl esters of palmitic and stearic acids. Palm oil, Chinese tallow, and Japan wax consist chiefly of the glyceride of palmitic acid. Spermaceti is cetyl palmitate, and the chief constituent of bees' wax is myricyl palmitate. The acid may be obtained by saponifying palm oil with caustic potash, decomposing the resulting soap with sulphuric acid, washing the precipitated acid with water, and recrystallizing from hot alcohol until a product is obtained having a constant melting-point. When pure it crystallizes in colorless odorless tasteless needles, melting at 62° C. (143.6° F.), and congeals to a mass of shining nacreous laminæ. It is soluble in boiling alcohol, the solution when concentrated solidifying on cooling. The alkali palmitates are important constituents of soaps: they separate in a gelatinous condition from water and alcohol.

Acidum Phtalicum. *Phtalic acid, Benzenedicarboxylic acid*, E.; *Phtalsäure*, G. $H_2C_8H_4O_2$ or $C_6H_4(COOH)_2$.—This acid is of interest to pharmacists chiefly in connection with morphine

phthalate, introduced into medicine, and phenolphthalein, a valuable indicator in alkalimetry. It is obtained by the action of nitric acid and other oxidizing agents on naphtalene; chromic acid mixture, however, cannot be used in its preparation, as it is easily oxidized thereby to carbon dioxide. Phtalic acid crystallizes in short prisms or laminæ, slightly soluble in cold water, and readily soluble in hot water, alcohol, and ether. It melts at 185° C. (365° F.), and at a higher temperature is resolved into its anhydride, $C_6H_4(CO)_2O$, and water. *Phenolphtalein* is made by heating phenol, phtalic anhydride, and sulphuric acid together at 120° C. (248 ° F.) for 8 or 10 hours, leaching the mixture with boiling water, and dissolving the residue in solution of sodium hydroxide. After filtration phenolphtalein is precipitated by acetic acid, dissolved in alcohol, decolorized with animal charcoal, and precipitated by addition of water.

Acidum Succinicum. *Succinic acid, Ethylene dicarboxylic acid*, E.; *Bernsteinsäure*, G. $H_2C_4H_4O_4$ or $(CH_2)_2(COOH)_2$.—The formation of a crystalline sublimate during the distillation of amber was observed first during the sixteenth century, but not until 1675 was its acid nature determined. Succinic acid, which derives its name from the Latin *succinum*, amber, is widely distributed in both the animal and vegetable kingdoms. When prepared by destructive distillation of amber it is generally contaminated with oil of amber, and may be purified by treatment with nitric acid and subsequent recrystallization. By this method about 5 per cent. may be obtained, while if powdered amber be treated with solution of potassium hydroxide the yield may be increased to 8 per cent. It occurs in colorless odorless prismatic crystals, which melt at 184° C. (363.2° F.) and are soluble in 20 parts of cold and 2.2 parts of boiling water; also soluble in 10 parts of 90 per cent. alcohol and in 80 parts of ether. The commercial acid frequently has a yellowish color and the odor of oil of amber. Succinic acid is rarely employed in medicine in this country. It has been recommended in rheumatism, bronchitis, and hysteria, but its administration is probably attended with little or no result. Solution of succinate of ammonium may be employed in hysterical affections, delirium tremens, and low fevers. The dose of the acid is stated to be from 5 to 15 grains (0.3–1 Gm.); of the solution of succinate of ammonium, from 10 to 30 minims (0.6–2 Cc.).

ACIDUM ACETICUM, *U. S., Br., P. G.*—Acetic Acid.

Acide acétique, Fr.; *Essigsäure*, G.; *Acido acetico*, It., Sp.

Formula, $HC_2H_3O_2$ or CH_3COOH. Molecular weight, 59.58.

History.—The substance known as vinegar, meaning sharp or sour wine, was known during antiquity. Its purification by means of distillation was taught by Geber (eighth century). The preparation of more concentrated acids by distillation of acetates, especially of copper and lead acetates, was known first to Basil Valentine (fifteenth century) and other alchemists. Wood vinegar was known to Glauber in 1648, but was examined only toward the close of the eighteenth century. The crystallization of pure acetic acid was observed by Lauraguais (1759). The preparation and properties of glacial acetic acid were, however, described in detail by Westendorf (1772) and by Löwitz (1789–1793).

Occurrence.—Acetic acid occurs extensively, though in small quantity, partly free, partly as salts (potassium and calcium acetates) or esters, both in the vegetable and the animal kingdoms. The hexyl ester has been found in *Heraclium sphondylium*, the octyl ester in *H. sphondylium* and *H. giganteum*, the menthyl ester in *Mentha piperita*, the bornyl ester in a number of coniferous (*Fichtennadel Oel*) and other oils, the terpinyl ester also, etc. The glyceride occurs in croton oil and other fatty oils.

Preparation.—Almost all of the acetic acid used in the arts and industries is obtained indirectly from wood. That used for culinary purposes (vinegar) is made principally by the acetous fermentation of dilute alcoholic liquids obtained by the vinous fermentation of grain (see Acetum).

Formerly much acetic acid was obtained in the form of wood vinegar or pyroligneous acid, by destructive distillation of oakwood in iron retorts kept at a temperature of 205° C. (401° F.). This crude acid liquid, of slightly yellowish color, was neutralized with soda-ash or sodium carbonate and evaporated, the resulting sodium acetate being then roasted to destroy empyreumatic products and to drive off water and other volatile matter. Upon finally treating the sodium acetate in suitable stills with sulphuric acid, purified acetic acid was obtained. This plan has, however, been abandoned by manufacturers, who now prefer to procure the acetic acid in the form of calcium acetate from charcoal-burners, and then bring this into solution and decompose it with sodium sulphate, whereby calcium sulphate is precipitated and sodium acetate remains in solution, which is then filtered and further treated as above explained.

If wood is distilled at a temperature above 230° C. (446° F.), as in the manufacture of charcoal, the resulting wood vinegar is more or less highly colored and possesses a strongly empyreumatic odor. It requires a tedious process of purification by means of milk of lime, whereby soluble calcium acetate is formed and many impurities are precipitated as insoluble calcium compounds.

Acetic acid may also be obtained direct from crude calcium acetate, and in order to avoid reaction of the strong sulphuric acid with the tarry impurities present, resulting in volatile products likely to contaminate the acid, it has been suggested to use polysulphates in place of the sulphuric acid. The liberation of acetic acid would occur as follows: $3Ca(C_2H_3O_2)_2 + 2NaH_3(SO_4)_2 = 6HC_2H_3O_2 + 3CaSO_4 + Na_2SO_4$.

Chemically, acetic acid may be looked upon as methane or marsh-gas (CH_4), in which an atom of hydrogen has been replaced by the carboxyl group, COOH, forming a monobasic acid; thus, $CH_3COOH = HC_2H_3O_2$. It is a remarkably stable acid, and, although rich in oxygen, is not decomposed at moderately high temperatures, nor is it readily affected by oxidizing or reducing agents.

Specific gravity is of no value in the examination of acetic acid, since the maximum density is reached in an 80 per cent. solution; beyond this point the specific gravity again decreases until absolute acetic acid is reached, having a density of 1.053. Official glacial acetic acid and an acid of 46 per cent. have the same specific gravity, 1.058 at 15° C. (59° F.), and, if diluted with water, the density of the weaker acid only will fall, that of the stronger acid increasing; between 72 and 84 per cent. acetic acid the specific gravity is almost stationary, the rise between these two points amounting to not more than 0.0008. Titration with normal alkali solution, as directed in the Pharmacopœia, is the only correct means of ascertaining the strength of acetic acid solutions, each Cc. of normal KOH solution corresponding to 0.05958 Gm. of absolute $HC_2H_3O_2$, as shown by the equation $KOH + HC_2H_3O_2 = KC_2H_3O_2 + H_2O$.

The following table, adopted by the U. S. P., shows the specific gravity at 15° C. and at 25° C. for acetic acid of different percentage strengths, and also the quantity of normal alkali required by 1 Cc. of these acids:

Per cent. absolute acetic acid.	Specific gravity— 25° C. / 25° C.	Specific gravity— 15° C. / 15° C.	Correction of specific gravity for 1° C.[1]	Fractional per cent.[2]	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc. normal KOH.

Note.—If the specific gravity $\left(\frac{25°\text{ C.}}{25°\text{ C.}}\right)$ of the acid be greater than 1.045, mix with some of the acid an equal weight of water before taking the specific gravity, and multiply the percentage taken from the table by two.

To find the weight in grammes of absolute acetic acid in 100 Cc., multiply the specific gravity by the per cent. of absolute acid.

To find the volume per cent. of official Acetic Acid, multiply the "normality" by 15.87. For the volume per cent. of Glacial Acetic Acid, multiply the "normality" by 5.71. For the volume per cent. of official diluted Acetic Acid, multiply the "normality" by 99.

[1] Below this point the specific gravity diminishes as the strength of the acid increases.

The U. S. Pharmacopœia recognizes three grades of acetic acid, which are designated officially as glacial acetic acid, acetic acid, and diluted acetic acid, and contain, respectively, 99, 36, and 6 per cent. of absolute $HC_2H_3O_2$. The three acids, recognized by the same names in the British Pharmacopœia, correspond very closely in strength to the above, containing 99, 33, and 4.27 per cent. of absolute acetic acid, respectively; but in the German Pharmacopœia the term acetic acid is used to designate a solution containing 96 per cent. of absolute acid, while the German diluted acetic acid contains 30 per cent.

I. **Acidum Aceticum**, U. S., Br.; *Acetic acid*, E.; *Acide acétique*, Fr.; *Essigsäure*, G.

Preparation.—The manufacture of acetic acid in general has been explained above. In all probability manufacturers and dealers prepare the official acid by simply diluting a stronger acid with the required quantity of water and standardizing the mixture with volumetric alkali solution. Acetic acid of 60 and 80 per cent. strength can be purchased from reliable manufacturers at relatively lower prices than the official acid. These can be diluted to suit any requirement by the following simple rule: Multiply the desired quantity (in grammes or avoirdupois ounces) by the required percentage and divide the product by the percentage of the stronger acid; the quotient will represent the quantity of stronger acid necessary to yield the desired quantity of weaker acid. Thus, if 1000 Gm. (or 100 ounces) of official acetic acid (36 per cent.) are to be made from 80 per cent. acid, it would be necessary to mix 450 Gm. (or 45 ounces) of the strong acid with 550 Gm. (or 55 ounces) of water; for 1000 (or 100) $\times$ 36 = 36,000 (or 3600), and 36,000 (or 3600) $\div$ 80 = 450 (or 45), then 1000 (or 100) — 450 (or 45) = 550 (or 55).

Properties.—Acetic acid occurs as a colorless, clear liquid of strongly acid reaction, vinegar-like odor, and pure acid taste. It is volatilized completely when heated, and mixes in all proportions with alcohol and water. If ferric chloride test-solution be added to acetic acid previously neutralized with ammonia water, a blood-red color, due to formation of ferric acetate, is produced, which is discharged by strongly acidulating with sulphuric acid.

The official acid has a specific gravity of 1.045 at 25° C. (77° F.), U. S., and 1.044 at 15.59° C. (60° F.), Br., which indicates a percentage of absolute acid amounting to 36 U. S. and 33 Br. *Acidum aceticum* of the P. G. and *Acide acétique du commerce* of the French Codex differ considerably from the above, the former being of 1.064 specific gravity and containing 96 per cent. of absolute acid, while the latter has a specific gravity of 1.060 and contains 49 per cent. of absolute acid.

Tests.—The transparency of the acid is not disturbed on diluting it with distilled water or alcohol; and on evaporating it on a water-bath no residue should be left (saline impurities). Calcium salts if present will produce a white precipitate upon addition of ammonium oxalate solution. Iron is detected best by the blue color or precipitate occasioned with potassium ferrocyanide; zinc, by the white precipitate; and the other metals, like copper, lead, or tin, by the brown or black color or precipitate formed on the addition of hydrogen sulphide after previous dilution with water. Empyreumatic products, if present in considerable proportion, may be detected by the odor after the acid has been diluted largely with water or neutralized with an alkali; smaller quantities are indicated by adding a minute quantity of solution of potassium permanganate, the color of which will disappear readily; pure acetic acid, containing less than 50 per cent. of absolute acid, is not affected by this test (Hager, Merck).

The U. S. P. directs proving the absence of copper by excess of ammonia (blue color); lead and other metals, by hydrogen sulphide (coloration or precipitate); sulphuric and hydrochloric acids, by barium chloride and silver nitrate (turbidity or precipitate); and formic or sulphurous acid, by neutralizing with ammonia and warming with silver nitrate (dark color and precipitate). The limit of empyreumatic substances is ascertained by diluting 2 Cc. of the acid with 10 Cc. of distilled water in a clear glass-stoppered vial, and adding 5 drops of decinormal potassium permanganate solution; the tint of the mixture should not change at once from pink to brown, and in half a minute should not be entirely free from pinkish brown. 5.96 Gm. of the acid should require 36 Cc., U. S. (1 Gm.—3.3 Cc., Br.), of normal potassium or sodium hydroxide solution for complete neutralization, using methyl orange as indicator.

II. **Acidum Aceticum Dilutum**, U. S., Br.; *Acetum purum s. destillatum.—Diluted acetic acid*, E.; *Acide acétique dilué*, Fr.; *Verdünnte Essigsäure, Reiner Essig*, G.

Preparation.—Diluted acetic acid is prepared by mixing 100 Gm. of acetic acid

with 500 Gm. of distilled water, U. S., or 1 part of acid with 5 parts of water (by weight). The Br. directs 1 volume of acetic acid to be mixed with 7 volumes of distilled water.

The diluted acetic acid of the P. G. is a much stronger preparation, containing 30 per cent. of absolute acid, and corresponds more nearly to the official acetic acid of this country and England.

Properties.—Diluted acetic acid has a specific gravity of 1.009 at 25° C. (77° F.), U. S. (1.006 at 15.59° C. (60° F.), Br.), corresponding to 6 per cent. (4.27 per cent., Br.) of absolute acid; therefore 23.8 Gm. of the acid require for neutralization 24 Cc., U. S. (10 Gm.—7.12 Cc., Br.), of volumetric solution of potassium hydroxide. The purity of diluted acetic acid is ascertained by the same tests mentioned for the stronger acid.

III. **Acidum Aceticum Glaciale,** U. S., Br.; *Glacial acetic acid,* E.; *Acide acétique crystallizable,* Fr. Cod.; *Esprit de vinaigre, Vinaigre glacial,* Fr.; *Eisesssig,* G.; *Acido acetico-concentrato,* It.

Preparation.—Glacial acetic acid is obtained by distilling anhydrous sodium acetate with concentrated sulphuric acid and exposing the resulting liquid to a temperature below 10° C. (50° F.); after crystallization has taken place the remaining liquid may be drained off and again exposed to cold, to secure a farther yield of crystals. It may also be prepared by distilling an intimate mixture of anhydrous sodium acetate and fused potassium sulphate, as suggested by Hirsch. Glacial acetic acid of official strength retains its crystalline form until a temperature of at least 15° C. (59° F.) is reached, when it slowly begins to liquefy; much of the so-called glacial acetic acid of commerce is simply a strong solution, containing from 75 to 85 per cent. of absolute acid, and does not solidify at a temperature of 5° C. (41° F.), or even lower.

Properties.—Glacial acetic acid forms colorless flat rhombic crystals, which melt on the application of heat to a colorless liquid, and this retains the fluid condition frequently on being cooled to 10° C. (50° F.), unless brought in contact with a crystal. At the mean temperature of the air it forms a colorless liquid with a strong acetous odor and very pungent, acid taste. It boils at 117°–118° C. (242.6°–244.4° F.), the vapor evolved burning with a blue flame.

The U. S. and Br. Pharmacopœias require glacial acetic acid to contain 99 per cent. of absolute $C_4H_2O_2$; but the melting-point is given at about 15° C. (59° F.), U. S., and above 15.5° C. (60° F.), Br., and the specific gravity as not above 1.049 at 25° C. (77° F.), U. S., and 1.058 at 15.5° C. (60° F.), Br., 1.063, Fr. Cod. An acid of the strength indicated is miscible in all proportions with alcohol, ether, and chloroform, and dissolves an equal weight of fresh oil of lemon, but less of the resinified oil. The oil is also far less soluble in weaker acetic acid, requiring about 10 parts of the latter if of 96 per cent. A more reliable test for the absence of water is carbon disulphide; equal parts of it and glacial acetic acid form, according to Flückiger, a clear solution at and above 20° C. (68° F.), but an opalescent or turbid liquid below that temperature. On neutralizing the acid 1.49 Gm. of it should require not less than 24.75 Cc. (1 Gm. 16.6 Cc., Br.) of normal potassium hydroxide solution (U. S.). The German Pharmacopœia recognizes glacial acetic acid under the simple name *Acidum Aceticum,* which is apt to give rise to confusion with the weaker acids of the same name used in other countries. It requires that the acid shall contain at least 96 per cent. of absolute $HC_2H_3O_2$. If this acid be mixed with 9 parts of water, 5 Cc. of the mixture will require not less than 8 Cc. of normal alkali solution for neutralization. The absence of arsenic is determined by mixing 1 Cc. of the acid with 3 Cc. of stannous chloride solution; the mixture should not acquire a brown or black color within 1 hour.

Glacial acetic acid absorbs moisture from the atmosphere, whereby its melting-point is lowered and its density increased to a certain degree. It must therefore be preserved in tightly stoppered bottles. For the detection of impurities, this acid is to be diluted with distilled water, and then tested as stated under Acidum Aceticum. It should respond to the same tests of purity; but the tint produced by the addition of 2 drops of decinormal potassium permanganate solution to 2 Cc. of the acid diluted with 10 Cc. of water, should not be changed to brown within 2 hours (U. S.).

Action and Uses.—Pure acetic acid is not used in medicine except in its dilute form (for action, uses, and dose, see Acetum).

Glacial acetic acid is used externally as a caustic in the removal of warts, corns, and vegetations about the external genitals. It may be employed as a vesicant when a very rapid action is desired, but should be applied with caution, because of its tendency to spread and involve too great an area.

ACIDUM AGARICUM.—Agaric Acid.

Agaricinum, P. G.—*Agaricin, Agaricic acid*, E.; *Acide agarique*, Fr.; *Agaricinsäure, Agaricussäure*, G.

Formula, $C_{16}H_{30}O_5 + H_2O$ or $C_{14}H_{27}(OH)(COOH)_2H_2O$. Molecular weight, 319.28.

Occurrence and Preparation.—Agaric acid occurs in the resinous principles of the larch agaric, and may be obtained as follows: Powdered agaric is exhausted with alcohol and the resulting solution concentrated by evaporation. Upon cooling, three white resins separate, while a red-colored resin remains in solution. By treating the white resins with warm 60 per cent. alcohol, impure agaric acid is extracted, which may be farther purified by dissolving in hot alcohol and adding an alcoholic solution of potassium hydroxide, whereby it is split up into alpha, beta, and gamma resins, the first two forming respectively soluble and insoluble potassium salts, while the last named does not combine with alkali. After filtering, the residue is treated with water and again filtered, whereby the gamma resin is removed. Upon addition of barium chloride to the filtrate, the barium salt of agaric acid is precipitated, which, after solution in boiling 30 per cent. alcohol, is decomposed with dilute sulphuric acid and filtered. Pure agaric acid crystallizes out from the filtrate while cooling.

Properties.—Agaric acid forms either a white amorphous or crystalliue powder; the microscope shows the latter to be made up of quadrangular plates. It fuses near 140° C. (284° F.) to a yellow liquid, which, when heated to a higher temperature, gives off white fumes and chars with a caramel-like odor; lastly, it burns, leaving no or only a trace of residue. It is soluble in 130 parts of cold and 10 parts of hot alcohol, more soluble in hot acetic acid and hot oil of turpentine, and only slightly soluble in ether, chloroform, benzene, and cold water; in hot water it swells, and when boiled dissolves, forming a clear and strongly foaming solution, which shows an acid reaction with litmus-paper, and on cooling becomes turbid. Agaric acid is a dibasic acid, crystallizing with 1 molecule of water, which it loses at 80° C. (176° F.); at higher temperatures the anhydride, $C_{16}H_{28}O_4$, is formed. Ammonia and potassium hydroxide solution should dissolve it. 0.1 Gm. of agaric acid dissolved in 15 Cc. of absolute alcohol yields with alcoholic potassium hydroxide solution a white precipitate which should be soluble in water. If 0.1 Gm. of agaric acid be boiled with 10 Cc. of diluted sulphuric acid, a turbid liquid results, which upon standing on a hot water-bath deposits oily globules, becoming crystalline on cooling.—P. G.

For uses, see Agaric.

ACIDUM ARSENOSUM.—Arsenous Acid.

See Arseni Trioxidum, page 243.

ACIDUM BENZOICUM, *U. S., Br., P. G.*—Benzoic Acid.

Acidum Benzoicum sublimatum, Flores benzoes.—Flowers of benzoin, E.; *Acide benzoique, Fleurs de benjoin*, Fr.; *Benzoesäure, Benzoeblumen*, G.; *Acido benzico*, It., Sp.

Formula, $HC_7H_5O_2$ or C_6H_5COOH. Molecular weight, 121.13.

Origin.—Benzoic acid is contained in benzoin, Tolu balsam, Peru balsam, storax, Botany Bay resin, in several other resinous exudations, and in certain plants. It was described by Vigenere (1608) as one of the products of the dry distillation of benzoin, and was recognized by Lemery (1675) and Scheele (1775) as an acid. Liebig (1836) found it among the products of the dry distillation of hippuric acid, and Dessaignes (1847) obtained it from the latter by the action of the acids and alkalies. Its artificial preparation is described below.

Preparation.—Benzoic acid may be obtained by subjecting benzoin in coarse powder, after removal of adhering moisture by careful warming or exposure over burnt

lime, to dry distillation in shallow iron pans. The pan is covered with a porous diaphragm, preferably of cloth, and then provided with a suitable condenser consisting either of a cap of thick, well-sized paper or a pasteboard hood or box suitably lined with glazed paper. The application of sand-bath heat should carefully be regulated, as the acid begins to sublime at 100° C. (212° F.), and at 140°–145° C. (284°–293° F.) is volatilized very freely. As the temperature is allowed to rise to 200° C. (392° F.) and over, the acid will be contaminated with other products, partly the result of decomposition, such as guaiacol, pyrocatechin, benzylbenzoate, vanillin, etc. The sublimed acid obtained from the cooled apparatus is used, but is never chemically pure; if made from good benzoin, the yield may reach 8 or 10 per cent., leaving often a still larger proportion in the fused resin, from which it may be obtained by the wet process, to be described presently, or the resinous mass may be broken again into small pieces and subjected to another sublimation.

The *wet process* for obtaining benzoic acid is carried on usually as follows: 4 or 5 parts of powdered benzoin and 1 part of lime are mixed with 10 parts of water, and the mixture allowed to stand in a warm place for some hours, replacing the water lost by evaporation; 50 parts of water are now added, the mixture boiled down to 30 parts, and filtered while hot. The residue is boiled again with water, and the mixed filtrates are supersaturated with hydrochloric acid. In this process, which is essentially that of Scheele (1775), the benzoic acid, together with a little resin, is rendered more freely soluble in water through the formation of calcium benzoate. This salt is decomposed in the filtrate by the hydrochloric acid, with the production of freely soluble calcium chloride and crystallizing benzoic acid, the latter being contaminated with some resin and coloring-matter, from which it may be freed by dissolving it in 20 times its weight of boiling water, adding some animal charcoal, filtering while hot, and crystallizing. In order to impart to the acid obtained by this method the peculiar aroma characteristic of the sublimed benzoic acid, it has been suggested to subject it to sublimation in the presence of benzoin, and possibly this plan is followed by some manufacturers.

Although sodium benzoate is about fifteen times more soluble in water than the calcium salt, and hence the acid might be prepared from it with smaller quantities of liquid, yet the use of sodium carbonate in the place of lime is not to be recommended, as the resulting acid will be found mixed with larger proportions of resin than that obtained by the lime process.

Hippuric acid, obtained from the urine of cattle or horses, consists of benzoyl glycocoll, and, if boiled with strong hydrochloric acid, absorbs water and is split up into benzoic acid and glycocoll (amidoacetic acid); thus, $C_6H_5CONH.CH_2COOH + H_2O = C_6H_5COOH + CH_2(NH_2)COOH$. Benzoic acid thus prepared has a fetid odor, and must be purified by recrystallization and sublimation with benzoin.

At present benzoic acid is manufactured extensively from toluene (toluol), $C_6H_5CH_3$, and probably the bulk of artificial acid is made now by this method. If chlorine gas be conducted into boiling toluene until an increase of weight is no longer perceptible, the latter body is converted into benzo-trichloride (trichlormethyl-benzene or phenyl chloroform), $C_6H_5CCl_3$. This liquid, when treated with water under pressure, yields benzoic and hydrochloric acids; thus, $C_6H_5CCl_3 + 2H_2O = C_6H_5COOH + 3HCl$. It is important that the chlorine gas be passed into the boiling toluene in diffused sunlight, since other products are formed when light is excluded.

The U. S. P. and Br. P. recognize the natural as well as the artificial benzoic acid, whereas the German Pharmacopœia specifies the acid obtained by sublimation from benzoin.

Benzoic acid occurs both in white and in yellowish-white feathery flexible crystalline flakes and needles, having, in case of the sublimed acid, an agreeable, aromatic odor, due to the presence of small quantities of volatile oil. It has a warm acidulous taste, and becomes darker in color when exposed to light. It is soluble in 400 parts (Br.), 370 parts (P. G.) of water, and in 2 parts of alcohol at 15° C. (59° F.); in 281 parts of water or 1.8 parts of alcohol at 25° C. (77° F.) (U. S.); in 15 parts (U. S.), 17 parts (Br.), of boiling water; and in 1 part of boiling alcohol. Also soluble in 3 parts of ether, 7 parts of chloroform, and readily soluble in carbon disulphide, benzene, fixed and volatile oils, but sparingly soluble in benzin. Its solubility in water is increased materially by sodium borate, sodium phosphate, and other salts. Benzoic acid begins to sublime at 100° C. (212° F.), melts at 121.4° C. (250.5° F.), and boils at 249° C. (480.2° F.) without decomposition. It volatilizes freely with the vapors of water.

The acid sublimed from benzoin has a lower melting-point and dissolves more freely in water than that obtained by other methods. On heating benzoic acid gradually with 3 parts of freshly slaked lime in a dry test-tube, benzene is evolved.

A solution of benzoic acid in strong sulphuric acid is colorless, and when gently warmed brownish, and on adding it to water benzoic acid again is precipitated; but the solution in fuming sulphuric acid, on being heated, gradually forms sulphobenzoic acid, $C_6H_4SO_3H.COOH$, which is deliquescent. Boiling nitric acid does not affect benzoic acid, but fuming nitric acid produces substitution compounds. Nascent hydrogen causes deoxidation, with the formation of benzaldehyde (oil of bitter almond) and benzalcohol, and the production of crystalline hydrobenzoic acid, $C_7H_{10}O_2$.

The salts of benzoic acid are more or less soluble in water, and many of them also in alcohol; those with the alkalies dissolve very freely in water. Solutions of the salts yield with neutral or basic ferric salts pale brownish-red, and with lead acetate and silver nitrate white precipitates, which are sparingly soluble in water.

Tests.—Benzoic acid should evaporate completely from platinum-foil. If much charcoal be left behind, the presence of other organic substances would be indicated, of which sugar manifests itself by the odor of caramel, and hippuric acid by the odor of hydrocyanic acid, during the application of heat, while mineral substances will be left as a fixed residue. Since some varieties of benzoin, notably the Sumatra, contain cinnamic acid, this should always be tested for before benzoic acid is prepared. The U. S., Br., and G. pharmacopœias have adopted a test indicating the limit of chlorine compounds that may be present, by igniting in a crucible a dried mixture of 0.5 Gm. of the acid, 0.8 Gm. of calcium carbonate, and a little water; the residue is dissolved in water and nitric acid to 20 Cc. of filtrate, in which the addition of decinormal silver nitrate solution should not produce more than a faint opalescence at the utmost. Cinnamic acid is detected readily by the odor of oil of bitter almond developed if 0.5 Gm. of benzoic acid, 0.5 Gm. of potassium permanganate, and 5 Cc. of water be warmed in a loosely stoppered test-tube to about 45° C. (113° F.) on a water-bath, and then tightly stoppering the tube and cooling with cold water.

Pure benzoic acid does not decolorize a solution of potassium permanganate, but the odorous compounds present in the sublimed acid rapidly deoxidize it, both in acid and alkaline solution. This test has been perfected by C. Schacht and others, and is applied by mixing 0.1 Gm. of the acid, and 5 drops of permanganate solution (1 : 200) with 5 Cc. of distilled water or with 3 Cc. each of potassium hydroxide solution, specific gravity 1.18, and distilled water, and heating the mixture just to boiling, when complete decoloration will be effected at once without the previous production of a green color. Benzoic acid, when prepared artificially or by the wet process, will either not reduce the permanganate or will effect it more slowly than the sublimed acid. For this reason C. Schneider has increased the test-liquid to 16 drops, which, when the mixture has been set aside for 8 hours, will be decolorized only by the sublimed acid, but not by the other kinds, even if resublimed with benzoin. In the presence of cinnamic acid reduction will likewise take place, but at the same time the odor of oil of bitter almond will be observed.

Pharmaceutical Preparation.—Lozenges of Benzoic Acid, Br.

Action and Uses.—Benzoic acid is strongly antiseptic, and in concentrated form irritates mucous membranes. Ordinary doses cause a sense of warmth over the entire body, which feeling increases with the amount ingested, large quantities causing severe burning pain. It may produce nausea and vomiting. It is said to be somewhat sedative to the central nervous system, and at times causes diaphoresis and increased expectoration. The drug increases the acidity of the urine, as it is eliminated by the kidneys as hippuric acid.

Senator recommends benzoic acid in the daily dose of 2 or 3 ounces (60–90 Gm.) in the treatment of rheumatic fever. It is stated, however, that while the drug may relieve the pain as well as salicylic acid, and is free from the untoward effects produced by the latter, yet it fails to reduce the temperature or quiet the pulse.

It may be given with benefit in phosphaturia, in incontinence of urine, and in cystitis due to alkalinity.

Benzoic acid is given in the dose of from 10 to 30 grains (0.60–2 Gm.). Being sparingly soluble in water, it is frequently combined with 4 parts of sodium phosphate or 1½ parts of sodium borate to aid in its solution.

ACIDUM BORICUM, *U. S.*, *Br.*, *P. G.*—Boric Acid.

Acidum boracicum.—*Boracic acid*, E.; *Acide borique crystallisé*, Fr. Cod.; *Borsäure*, G.; *Acido borico*, F. It.

Formula, H_3BO_3 or $B(OH)_3$. Molecular weight, 61.54.

Origin and Preparation.—This acid was obtained by Homberg (1702) by heating borax with copperas, and subsequently from sulphuric acid and borax. It was known as *Sal sedativum Hombergi* until Gay-Lussac and Thénard (1804) proved it to be an oxygen compound of boron. It is a constituent of several minerals, especially in the niter-regions of Chili and Peru, as *borocalcite*. It is present, mostly in minute quantities, in various plants, mineral waters, and sea water, and in somewhat larger proportion in several of the hot springs in Western North America. It has been found in large quantity as a constituent of borax in Borax Lake, California, and it also occurs in the same form as *tincal* in the dried-up saline lagoons or lake-beds of Thibet. The major part of the boric acid consumed in the United States is now derived from California, while the greater part of the world is supplied from Tuscany, Italy, and the Liparian island of Volcano, north of Sicily. The crater of Volcano contains a deposit of boric acid mixed with sulphur, known as *sassoline*, and the same acid is found in the vapors which issue from fissures in the volcanic rocks of Tuscany. These fissures, called *soffioni*, are either natural or made artificially by drilling, sometimes to the depth of 150 to 200 feet. Surrounding one or more of the *soffioni* a series of basins or *lagoons* are constructed on the side of the mountain, either by excavation or masonry, and are then filled with water from a mountain-stream; the hot vapors in passing through the water yield to it boric acid and heat the water at the same time. The solution of boric acid thus obtained is passed from one basin to another lower one, and when sufficiently saturated into a reservoir; thence it is conducted into evaporating-pans, and finally into vats, where the acid is deposited. This crude product is used in the preparation of borax (see Sodii Boras), and from this salt boric acid is again prepared for medicinal use. The American production of refined borax, including boric acid, was 21,422,300 pounds in 1897.

10 parts of borax are dissolved in 24 parts of boiling water; the solution is filtered while hot, mixed with 6 parts of hydrochloric acid, and the liquid set aside for a day in a cool place. The crystals are collected either in a funnel or upon a strainer, and are drained and washed with a little cold water, after which they are redissolved in 5 times their weight of boiling distilled water. After a day or two the crystals are collected as before, washed with cold water to remove the last traces of adhering hydrochloric acid, and dried in a moderately warm place. The yield is between 5½ and 6 parts. The reaction which takes place is explained by the equation: $Na_2B_4O_7.10H_2O + 2HCl = 4H_3BO_3 + 2NaCl + 5H_2O$. Sulphuric acid may be employed in the place of hydrochloric acid, but will adhere more persistently to the boric acid, necessitating two or three recrystallizations.

Properties.—Boric acid crystallizes in white translucent six-sided scales, which have a slight pearly luster, are somewhat unctuous to the touch, inodorous, and of an acidulous and slightly acrid taste. It is soluble at 25° C. (77° F.) in 18 parts of water, 15.3 parts of alcohol, or 4.6 parts of glycerin; also soluble in 3 parts of boiling water and in 4.3 parts of boiling alcohol (U. S.). Addition of hydrochloric acid increases its solubility in water. The P. G. says boric acid is slowly soluble in 25 parts of cold water, 3 parts of boiling water, and 15 parts of alcohol. According to the Br. P., the acid is soluble in 30 parts of cold water, 3 parts of boiling water, 30 parts of alcohol (90 per cent.), and 4 parts of glycerin. The taste of the solutions is somewhat astringent and sweetish, and in the presence of salicylic acid quite bitter. When heated, it melts, disengaging vapors of water, which contain some of the acid; between 80° and 100° C. (176° and 212° F.) it is converted into *metaboric acid*, HBO_2; between 140° and 160° C. (284° and 320° F.) it yields tetraboric or *pyroboric acid*, $H_2B_4O_7$; and at a red heat all the water is expelled, *boric anhydride*, B_2O_3, being left in the form of a transparent, very hard but brittle glass, and weighing about 56 per cent. or less of the boric acid used. Boric acid volatilizes appreciably with water at and above 60° C. (140° F.), and with the vapors of boiling alcohol; its solution in the latter burns with a green flame. It is nearly insoluble in ether, soluble in volatile oils. The aqueous solutions impart a red color to blue litmus-paper and a brownish-red color to turmeric-paper upon drying the latter. The last-named reaction is produced also in the presence of diluted

mineral acids, which distinguishes boric acid from alkalies. On touching the brown part with ammonia-water it changes to blackish blue (a delicate and characteristic test).

Boric acid, mixed with the salts of mineral acids and ignited, decomposes all those containing volatile acids; in aqueous solution it decomposes the carbonates only, forming borates, of which those with an alkaline base are readily soluble in water, while most others are slightly soluble or nearly insoluble. On ignition they melt to a glass-like mass; and when mixed with sulphuric acid and alcohol, on igniting the latter the green flame of free boric acid is observed.

Tests.—In addition to its fusibility, and its complete solubility in water and alcohol, boric acid, dissolved in 50 parts of distilled water acidulated with nitric acid, should yield no precipitate with the nitrates of silver and of barium (absence of hydrochloric and sulphuric acids), and no dark color with hydrogen sulphide either before or after neutralization with ammonia (metals). The solution of 1 Gm. of the acid in a mixture of 1 Cc. of hydrochloric acid and 49 Cc. of distilled water should not at once assume a blue color on the addition of 0.5 Cc. of potassium ferrocyanide solution (limit of *iron*); nor should it, when heated on a clean platinum wire, impart to a non-luminous flame a persistent yellow color (absence of *sodium*). The absence of earths is determined by testing a 2 per cent. aqueous solution of boric acid with ammonium oxalate for calcium, and with sodium phosphate and ammonia water for magnesium, which reagents should yield no precipitates (U. S.). If mixed with an excess of sulphuric acid, the addition of a crystal of ferrous sulphate should not cause the appearance of a dark-brown color (absence of nitrates). 5 Cc. of a saturated aqueous solution of boric acid should not respond to the modified Gutzeit's test for arsenic (U. S.); see ARSENI TRIOXIDUM, page 243.

Free boric acid may be determined quantitatively either gravimetrically or volumetrically.

a. Gravimetrically.—If only boric acid is present in the solution, add a weighed and sufficient quantity of ignited sodium carbonate, evaporate to dryness and ignite the residue. The acid drives out an equivalent amount of CO_2. The remaining CO_2 is then determined, and the difference between this and the total weight of carbon dioxide in the carbonate taken gives the weight of the same displaced by the boric acid, from which the boric acid is calculated, using the equation: $2B(OH)_3 + nNa_2CO_3 = 2Na_3BO_3 + 3H_2O + 3CO_2 + (n-3)Na_2CO_3$ (Fresenius, *Quant. Anal.*, I. and II.).

b. Volumetrically.—The U. S. P. demands not less than 99.8 per cent. purity for boric acid, to be determined as follows: 1 Gm. of boric acid, when dissolved in 50 Cc. of warm distilled water, after addition of 50 Cc. of glycerin, should require not less than 16.28 Cc. of normal sodium hydroxide solution for neutralization, phenolphthalein test-solution being used as indicator.

Estimation in Surgical Dressings.—5 Gm. of borated cotton or gauze are cut up and extracted in a 500 Cc. flask by repeated shaking with a mixture composed of 1 part of glycerin and 19 parts of water. The flask is then filled to the mark with more of the mixture. 100 Cc. are removed with a pipette, mixed with 40 Cc. of glycerin, and titrated with decinomal NaOH (free from CO_2). The boric acid is calculated from the number of Cc. of alkali used (1 Cc. = 0.006154 Gm. of $B(OH)_3$), and this will be the weight in 1 Gm. of material. Addition of more glycerin should not remove the phenolphthalein red color at the end of the operation. If it does, a new titration must be made, using more glycerin (Hager's *Handbuch*, 1899).

Glycerin, like manna, has the property of increasing the acidity of boric acid, so that it may be neutralized fully by alkalies. Ordinarily, on adding alkalies to boric acid solution the neutral point is reached before the boric acid has been converted fully into borate.

Louis Cleveland Jones (*Am. Jr. Sc.*, 1899 (4), vii.) describes a method for determining boric acid, free or in combination, volumetrically, by the use of mannite to increase the acidity of the acid. For details of the operation, consult the original article, of which a reprint is given in *Chem. News*, Aug. 11, 1899.

Pharmaceutical Preparations.—GLYCERITE OF BOROGLYCERIN, U. S.; OINTMENT OF BORIC ACID, Br.

Action and Uses.—Boric acid has been employed as a mild antiseptic and detergent, but it does not possess germicidal properties. It is absorbed so rapidly that it is of

no value as an intestinal antiseptic. The drug is eliminated principally by the kidneys, and its administration increases the acidity of the urine. It has little effect upon the animal organism unless taken in enormous amounts or given for a long time, when it may produce a scarlatiniform rash, eczema of the skin of the joints, with local swellings and œdema. Such doses may cause gastro-intestinal inflammation, with nausea, vomiting, and diarrhœa. Not uncommonly emaciation, great muscular weakness, and insomnia follow its prolonged use.

Internally boric acid is useful in the treatment of cystitis due to alkalinity of the urine, and it has been largely used in epilepsy. As a lotion it has been employed with some success in erysipelas and in the treatment of burns and scalds; in the latter conditions, however, this remedy has been supplanted largely by the solution of hydrogen dioxide.

Because of its mild antiseptic and non-irritative properties boric acid is widely used in inflammatory conditions of the eye, ear, nose, and throat. It is especially useful as an eye wash, and has been highly recommended in chronic otitis media, in which condition the drug may be used either in solution or in powder by insufflation.

The dose of boric acid is from 5 to 10 grains (0.30–0.60 Gm.) 4 times daily. The strength of the solution for local application to the conjunctiva is from 5 grains to the ounce up to saturation.

Boric acid ointment may be prepared by incorporating 4 parts of hot boroglycerin in a mixture of 1 part of spermaceti and white wax and 6 parts of petrolatum. Lister's boric acid ointment contains 1 part each of boric acid and white wax, and 2 parts each of the oil of sweet almond and paraffin.

Combinations of Boric Acid.—Boralid, a mixture of equal parts of boric acid and acetanilid: in eczema.

Boricin, a mixture of borax and boric acid.

Borocitric acid, a combination of the two acids; a white soluble powder, used as solvent for phosphates and urates in calculi, gout, etc.

Boroformol, Boroformalin, made by solution of aluminum hydroxide in a mixture of 2 parts of formic acid and 1 part of boric acid, and evaporating to dryness. Soluble white scales; antiseptic, deodorant.

Borol, borosulphate of sodium or potassium, $SO_2(OBO)(OK)$. A powerful antiseptic in infectious diseases.

Borophenylic acid, phenyl-boric acid, $C_6H_5B(OH)_2$. Obtained by condensation of phenol and boric acid by means of phosphorus oxychloride. Difficultly soluble white powder of mild taste. Antiseptic, preservative, 1:5000.

Borosalicyl, an antiseptic, containing 32 parts of sodium salicylate to 25 parts of boric acid.

Borosalicylic acid, solution of 4 per cent. each of boric and salicylic acids. Antiseptic.

Glacialin, which has been recommended as an antiseptic and for the preservation of articles of food, is a mixture of boric acid 6 parts, borax 3 parts, sugar 3 parts, and glycerin 2 parts.

Glybolid, a paste of 2 parts of glycerin, 1 part of boric acid, and 1 part of acetanilid. For pustules, abscesses, etc.

Wickersheimer's Preserving Fluid.—50 Gm. of boric acid, 20 Gm. of sodium chloride, 7.5 Gm. of salicylic acid, 250 Gm. of glycerin, and water sufficient to make 500 Cc.

ACIDUM CAMPHORICUM, *U. S.*, *P. G.*—Camphoric Acid.

Acide camphorique, Fr.; *Kamphorsäure*, *Kamphersäure*, *Kamphylsäure*, G.

Formula, $H_2C_{10}H_{14}O_4$ or $C_8H_{14}(COOH)_2$. Molecular weight, 198.62.

Preparation.—Camphoric acid is obtained by heating on a boiling water-bath a mixture of 150 Gm. of camphor and 2000 Cc. of nitric acid, specific gravity 1.37, in a long-neck flask, provided with a reflux condenser consisting of a long straight glass tube, until colored vapors are no longer given off. The operation should be conducted in the open air or in a fume chamber, and may be hastened by gently boiling the mixture over a direct flame. When cool, the liquid is filtered through asbestos or glass-wool for the purpose of collecting the crystals of camphoric acid which have separated; the filtrate is reduced by evaporation to about one-fifth of its volume, and an additional crop of crystals thus obtained. The crystals are next dissolved in 5 parts of water with the aid of sodium carbonate, and the slightly alkaline solution of sodium camphorate filtered and allowed to crystallize; after solution in 10 parts of water the sodium camphorate is decomposed by an excess of hydrochloric acid. The liberated camphoric acid will crystallize out, and may further be purified by redissolving in

hot water, treating with animal charcoal, and recrystallizing. The acid mother-liquid from which the crude camphoric acid was first obtained contains *camphoronic acid*, $C_6H_{11}(COOH)_3$, a tribasic acid, melting at 136° C. (276.8° F.).

Properties.—Camphoric acid occurs in acicular scales free from color and odor. It is soluble in about 150 parts of water at 15° C. (59° F.), 125 parts at 25° C. (77° F.) (U. S.), 8 parts of boiling water, readily soluble in alcohol and ether, but less so in chloroform; its solutions redden blue litmus-paper. The acid melts at 187° C. (368.6° F.), and at higher temperatures it loses water and is volatilized completely in the form of white vapors of pungent odor, consisting of camphoric anhydride. It is a dibasic acid, and forms readily soluble and crystallizable salts with the alkalies, calcium, barium, and magnesium. Camphoric acid is dextrorotatory, showing in 10 per cent. alcoholic solution the value $(\alpha)_D = +47.8°$ (U. S.).

Tests.—A cold saturated aqueous solution of camphoric acid should not be affected by test-solutions of barium chloride and silver nitrate, showing absence of sulphuric and hydrochloric acids. If 2 Cc. of a saturated aqueous solution of camphoric acid be mixed with 2 Cc. of sulphuric acid in a test-tube, and 1 Cc. of a solution made by dissolving 1 Gm. of ferrous sulphate in 2 Cc. of diluted sulphuric acid be poured carefully upon it, no dark-colored zone should develop at the line of contact (absence of *nitric acid*) (U. S.). 1 Gm. of camphoric acid previously dried requires for complete neutralization 10 Cc. of normal alkali solution, using phenolphthalein as indicator (P. G.).

Action and Uses.—Camphoric acid is quite largely employed to combat the night-sweats of phthisis, for which condition it should be given upon retiring; or if the sweats occur in the morning, it should be taken about the middle of the night. 1 per cent. solutions of the drug may be employed successfully in the treatment of pharyngitis and laryngitis; and in chronic cystitis, irrigation of the bladder with a solution of the same strength will often prove of service. Camphoric acid has also been recommended internally in pulmonary tuberculosis, cystitis, pyelitis, chronic gonorrhœa, and in diarrhœa resulting from intestinal fermentation.

The dose for internal administration is from 10 to 30 grains (0.60–2 Gm.), usually in powder or capsule. In combating colliquative sweats, it is well to give full doses.

ACIDUM CARBOLICUM, *Br., P. G.*—Carbolic Acid.

Phenol, U. S.; *Phénol, Acide carbolique, Acide phénique*, Fr. Cod.; *Karbolsäure*, G.
For full description, see PHENOL, page 1158.

ACIDUM CARBOLICUM LIQUEFACTUM, *Br., P. G.*—Liquefied Carbolic Acid.

Phenol liquefactum, U. S.; *Phénol liquefiée*, Fr.; *Verflüssigte Karbolsäure*, G.
For full description, see PHENOL LIQUEFACTUM, page 1163.

ACIDUM CARBONICUM.—Carbonic Acid.

Carbonic acid, Carbonic anhydride, Carbon dioxide, E.; *Acide carbonique*, Fr.; *Kohlensäure*, G.

Formula, CO_2. Molecular weight, 43.67.

Occurrence and Preparation.—Carbonic acid gas, as it exists in certain mineral waters, was regarded by Libavius (1597) as a very volatile spirit. In the following century Van Helmont distinguished it and other irrespirable gases from atmospheric air as "spiritus sylvestris" or "gas sylvestre." In the beginning of the eighteenth century F. Hoffmann recognized the acid character of carbonic acid in mineral waters, and called it "spiritus mineralis." Joseph Black (1755) observed that this "fixed air" combined with alkalies and earths and increased their weight. Lavoisier (1775) proved this gas to be composed of carbon and oxygen.

Carbon dioxide gas is a regular constituent of the atmosphere, in which it is present to the extent of 0.03 per cent. by volume or about 0.05 per cent. by weight. In certain localities it issues from fissures in considerable quantity; at Brohl, Germany, about 660 pounds (300 Kgm.) of the gas escape from the earth in 24 hours. It is a product of respiration

of animal life (exhaled air containing 4–5 per cent. of CO_2) and of alcoholic fermentation, exists in combination in many minerals, and is formed on the complete combustion of carbon or organic compounds in the presence of an excess of oxygen; diamond and graphite require a high heat for their combustion. The best sources for preparing carbon dioxide in a pure state are whiting, marble-dust, or similar native carbonates, which are decomposed by dilute sulphuric acid in an apparatus provided with a stirrer to prevent the calcium sulphate formed from enveloping the undecomposed carbonate. On a small scale, and for obtaining a uniform current of carbon dioxide gas, fragments of marble and diluted hydrochloric acid are used, whereby calcium chloride is formed, together with some water, and remains in solution: $CaCO_3 + 2HCl$ yields $CaCl_2 + H_2O + CO_2$. Should the gas possess a disagreeable odor, it may be deprived of it, according to Stenhouse, by passing it over granular charcoal, or, according to Hager (1868), by conducting it successively through solutions of ferric sulphate, sodium carbonate, potassium permanganate, and water, by which treatment it is freed from hydrogen sulphide and hydrocarbons.

A cheap source of carbon dioxide is sodium bicarbonate, which yields about half its weight of the gas, and when decomposed by sulphuric acid gradually added will, in addition, produce 15 parts of crystallized sodium sulphate for every 4 parts of the bicarbonate used: $2NaHCO_3 + H_2SO_4 = Na_2SO_4 + 2H_2O + 2CO_2$.

Properties.—Carbonic acid—or, more properly, carbon dioxide—is a colorless, uninflammable gas, which has a slight pungent odor and pricking, acidulous taste, colors moist litmus-paper transiently red, and does not support combustion. It is heavier than atmospheric air, its specific gravity at 0° C. (32° F.) being 1.529 as compared with atmospheric air, and 1 liter of it weighing 1.9781 Gm. at 0° C. (32° F.) and 760 Mm. pressure. By pressure it is converted into a very mobile colorless liquid, which is lighter than water, and on removal of the pressure boils rapidly and is partly converted into white flakes of solid carbonic anhydride. At 0° C. (32°F.) the pressure required is 36 atmospheres, at 20° C. (68° F.) about 59 atmospheres, at 30° C. (86° F.) 73 atmospheres. The temperature of liquid carbonic acid, boiling freely at atmospheric pressure, falls to —78° C. (—108.4° F.). The gas dissolves at 15° C. (59° F.) in an equal volume of water, and is more soluble in alcohol, absolute alcohol at 15° C. (59° F) dissolving 3 volumes of the gas, which is partly expelled on dilution with water. It unites with most of the basic hydroxides, forming salts which, with the exception of the alkali carbonates, are insoluble in water, but dissolve to a slight extent in carbonic acid water and are decomposed by all mineral and most organic acids. Carbonic acid is dibasic; all the acid carbonates (bicarbonates) are decomposed by heat, carbon dioxide being evolved.

Technical.—Carbon dioxide is used extensively for various purposes; for example, the production of low temperature, sparkling waters, high pressures, etc., in consequence of which it is prepared now on the large scale and stored in strong steel cylinders in liquid form. Many industrial operations give rise to immense quantities of the gas, such as beer, wine, and spirit fermentation, reduction processes in metallurgy, lime-burning, besides issuing from vents in the earth in certain localities (volcanic). It is collected from these vents in large gasometers and liquefied by pressure. In the case of impure gases, the carbon dioxide is separated from other gases by absorption in sodium carbonate solution, which forms bicarbonate, from which the carbon dioxide is driven out again by heating, collected, and liquefied by pressure.

In 1899 there were in Germany about 80 factories engaged in making liquid carbon dioxide. At Bernhardshall alone 600 tons are produced yearly. In 1897 the total production in Germany was 11,000 tons.

The Pabst Brewing Co., at Milwaukee, was the first to introduce a system of carbon dioxide gas collection; in 1897 more than 1,500,000 pounds were liquefied, and double this quantity in 1898. This plant could furnish 10,000,000 pounds of the gas annually from the 1,000,000 barrels of beer brewed.

Pharmaceutical Uses.—In pharmacy carbon dioxide is employed almost exclusively in the preparation of carbonic acid water.

Aqua Acidi Carbonici, U. S. 1870; *Aqua acidula simplicior*, Fr. Cod.; *Aqua carbonica. Carbonic acid water*, E.; *Eau gazeuse simple*, Fr.; *Kohlensäure-Wasser, Brausewasser*, G.—This water is prepared very extensively in the United States and sold under the names of *soda water* and *mineral water*. Several apparatus have been constructed and patented for the convenient preparation of carbon dioxide and for charging water with this gas under

pressure. They consist of a generator, a strong copper vessel, into which the powdered marble, whiting, or sodium bicarbonate is introduced with some water, and which connects with another copper vessel containing the sulphuric acid, which is admitted in small quantities. The gas is passed first through a vessel containing water, to deprive it of impurities, and then to the bottom of the fountain, as the receiving vessel is called, containing the requisite quantity of water. The fountains are made either of cast iron, well protected on the inside by enamel, or of copper lined with block-tin; or stoneware fountains, secured by iron bands, are employed. The water, which usually is charged with from 8 to 10 times its volume of carbon dioxide, is drawn off through block-tin pipes, which pass through a chamber containing ice. Carbonic acid water has an agreeable acidulous and refreshing taste, and effervesces strongly. It produces white precipitates with lime and baryta water, and acts upon iron, lead, and copper, which metals are dissolved gradually; tin and silver are affected less; hence the importance of preventing the water from coming in contact with other metals except the two last mentioned. It should not be discolored by hydrogen sulphide nor ammonia, and should yield no precipitate with sodium sulphate or with potassium ferrocyanide.

Action and Uses.—Inhalations of pure carbonic acid produce asphyxia and death. Small quantities largely diluted with air first stimulate and later depress the nervous, respiratory, and circulatory systems; the reflexes are decreased, the pulse becomes slow and weak, and the respirations very shallow. Locally applied, it acts as a stimulant to both the skin and mucous membranes, producing a sensation of tingling and causing considerable redness. Carbonic acid is absorbed by the skin and mucous membranes and eliminated by the lungs. Very large amounts are said to cause the blood to become overcharged.

Internally in the form of carbonated waters small amounts increase digestion. These waters have been employed as diuretics, but when given in large quantities are apt to derange digestion. Inhalations of the diluted gas have been recommended in pulmonary tuberculosis, but are of doubtful efficacy. Carbonated waters relieve thirst more readily than plain water, and are grateful in feverish conditions (see Carbonated Waters).

ACIDUM CHROMICUM, *Br., P. G.*—Chromic Acid.

Chromii trioxidum, U. S.; *Acide chromique cristallisé*, Fr. Cod.; *Chromsäure*, G.
For full description, see CHROMII TRIOXIDUM, page 416.

ACIDUM CHRYSOPHANICUM.—Chrysophanic Acid.

Chrysophansäure, Rhein, Rheïnsäure, Rhabarbergelb, Parietinsäure, G.; *Dioxymethylanthraquinone.*

Formula, $C_{15}H_{10}O_4$ or $C_6H_2(CH_3)(OH)\begin{<}{l}CO\\CO\end{>}C_6H_3.OH$. Molecular weight, 252.17.

This acid is a constituent of rhubarb, also of *Rumex obtusifolius* and senna leaves, but is not found in the yellow lichen, *Parmelia parietina*, from which Rochleder and Heldt thought they had isolated it. Chrysophanic acid formerly was regarded identical with chrysarobin.

Preparation.—Remove extractives from rhubarb cut in small pieces as completely as possible by exhausting with water, then extract the residue with dilute alkali, filter the liquid, and acidify with acetic acid, whereupon chrysophanic acid is thrown down. Wash the precipitate with water, dry, and recrystallize from hot ligroïn or benzene.

A second method consists in mixing chrysarobin powder with a large volume of dilute alkali in a wide flask, passing air into the liquid, and shaking until all chrysarobin has been dissolved and a uniform red solution obtained. The filtered solution is acidified with dilute hydrochloric acid and the precipitate treated as above. In this process chrysarobin is oxidized to chrysophanic acid; thus, $C_{30}H_{26}O_7 + O_4 = 2C_{15}H_{10}O_4 + 3H_2O$.

Properties.—Chrysophanic acid forms golden-yellow, tasteless, clinorhombic prisms, insoluble in water, soluble in 224 parts of boiling alcohol (81 per cent.), in acetic acid, chloroform, benzene, and benzin. It dissolves in caustic alkalies with a red color, and in concentrated sulphuric acid with a deep-red color (contrast to chrysarobin, which gives a yellow color with sulphuric acid). Fused with potassium hydroxide, it gives a blue, chrysarobin, a yellow mass. It melts at 162° C. (323.6° F.). No residue is left on incinerating the acid.

Action and Uses.—Chrysophanic acid is occasionally employed locally in the treatment of skin diseases, for example, psoriasis and chronic eczema, but is not so commonly used as chrysarobin, a substance closely allied to it. (For action and uses, see Chrysarobinum.)

ACIDUM CITRICUM, *U. S., Br., P. G.*—Citric Acid.

Acidum citri, s. limonum, s. limonorum.—Acide citrique, A. du citron, Fr.; *Citronensäure,* G.; *Acido citrico,* It., Sp.

Formula, $H_3C_6H_5O_7 + H_2O$ or $C_3H_4(OH)(COOH)_3 + H_2O$. Molecular weight, 208.5.

History.—The activity of lemon-juice was known to the ancients, but it was not until 1776 that Retzius distinguished it from tartaric and other vegetable acids. Scheele in 1784 obtained it in the crystalline form. Its synthesis was accomplished by Grimaux and Adam (1880) by the hydrolysis of the dicyanide from s-dichlor-hydroxyisobutyric acid, $(CH_2Cl)_2.C(OH).COOH$, with hydrochloric acid. Inasmuch as the s-dichlor-hydroxyisobutyric acid can be obtained through the cyanhydrin reaction from s-dichlor acetone, the synthesis of citric acid can be referred back to acetone and farther. A more direct synthesis is from acetone dicarbonic acid, $CO(CH_2COOH)_2$, by means of the HCN reaction.

Occurrence.—Citric acid occurs widely distributed in nature, in the free state and as salts, also associated with tartaric and malic acids. It occurs free and with little or no malic acid in the fruits of *Vaccinium vitis idæa, V. oxycoccus, Prunus padus;* and especially pure and abundant in the not quite mature fruits of the orange family (lemon, bergamot, etc.). Associated with other acids, it is found in cherries, raspberries, gooseberries, strawberries, tamarinds, etc.; also in the roots, leaves, and bark of various plants.

Preparation.—Citric acid is manufactured in this country and in Europe on a large scale from lemon- and lime-juice. The juice is employed either in its natural condition or considerably concentrated by evaporation, or else in the form of a crystalline powder as calcium or magnesium citrate. The juice is clarified by ebullition, or, if obtained from unsound fruits, by allowing it to undergo the vinous fermentation. After decantation and straining, an excess of chalk is added, and finally some milk of lime. The calcium citrate, $Ca_3(C_6H_5O_7)_2.4H_2O$, thus formed being less soluble in hot than in cold water, the mixture is heated to boiling, and while hot the clear liquid is drawn off from the precipitated calcium citrate, which is washed with boiling water for the purpose of removing all the extractive matter. The calcium citrate is now decomposed by diluted sulphuric acid in such a proportion as to form calcium sulphate, and to leave a little sulphuric acid in excess: 10 parts of calcium citrate require about 9 parts of sulphuric acid diluted with from 50 to 60 parts of water. The solution of citric acid is drawn off from the precipitated calcium sulphate, and the latter washed with very cold or with boiling water, in which gypsum is less soluble than in water of a medium temperature. The liquid, with the washings, is evaporated by steam heat to a syrupy consistence, and then allowed to crystallize in suitable tanks lined with lead. The presence of a little sulphuric acid appears to favor crystallization, which is prevented or considerably retarded by acid calcium citrate. The crystals are redissolved in a small quantity of water, and the solution is treated with animal charcoal and then evaporated to crystallize. Citric acid may be prepared by this process from the juice of other acidulous fruits; Græger (1873) described the manipulations necessary to obtain it advantageously from whortleberries.

During the past few years citric acid has been prepared from dextrose (grape-sugar) by the action of certain fungi, known as citromyces. The yield amounts to about 55 per cent. of the weight of dextrose used, and the resulting citric acid is in every respect identical with the natural acid. The manufacture of artificial or synthetic citric acid is said to be already in progress on a commercial scale.

Properties.—Citric acid crystallizes in colorless rhombic prisms which have an agreeable acid taste. The solubility is variously stated as follows: U. S. Pharmacopœia, at 25° C. (77° F.), 1 part of acid in 0.54 part of water, 1.08 parts of alcohol, and in 18 parts of ether; also soluble in 0.4 part of boiling water and in 1.43 parts of boiling alcohol. British Pharmacopœia, temperature not specified, but 15.5° C. (59° F.) gen-

erally understood, 1 part of acid soluble in 0.75 part of water, less soluble in alcohol of 0.835 specific gravity, and insoluble in ether; also soluble in 0.5 part of boiling water. German Pharmacopœia, at 15° C. (59° F.), 1 part of acid soluble in 0.54 part of water, 1 part of alcohol, and in 50 parts of ether. It is also soluble in methyl and amyl alcohols and glycerin, and is freely soluble in hot creosote, but insoluble in chloroform and in hydrocarbons, except in the presence of alcohol. When a solution is made by dissolving 40 grains of the crystals in 1 ounce of water, it resembles lemon-juice in strength and in the nature of its acid properties, and, like lemon-juice, it undergoes decomposition, acetic acid being among the products, and becomes mouldy by keeping. The crystals are permanent in dry air, but at a somewhat elevated temperature, beginning at 35°–40° C. (95°–104° F.), slowly part with their water of crystallization, and in a damp atmosphere they become moist and gradually deliquesce. The anhydrous acid fuses between 152° and 153° C. (305.6° and 307.4° F.). When slowly ignited, it is decomposed gradually without emitting the odor of burning sugar (difference from tartaric acid), and is consumed finally without leaving more than 0.05 per cent. of residue (U. S.).

Citric acid is a tribasic acid, having the formula $H_3C_6H_5O_7$, or, as met with in the crystallized condition, $H_3C_6H_5O_7 + H_2O$. The water of crystallization, amounting to 8.6 per cent., is expelled at 135° C. (275° F.), and at 155° C. (311° F.) another molecule of water is given off, *aconitic acid*, $H_3C_6H_3O_6$, remaining behind, which is identical with the acids that have been isolated from aconite, yarrow, and other plants. Like citric acid, it forms three series of salts, either 1, 2, or 3 atoms of hydrogen being replaceable by a basylous radical.

The citrates of the alkalies are all soluble in water; the neutral citrates of the heavy metals are mostly insoluble in water, but dissolve in nitric, and many also in citric acid. Ferric and aluminum citrates are not precipitated by alkalies. That the calcium citrate is soluble in cold and insoluble in hot water has been mentioned. If lime water is not completely neutralized by solution of citric acid, no precipitate will occur until the liquid is heated to boiling. 3.5 Gm. of citric acid dissolved in distilled water are neutralized by 50 Cc. of normal alkali solution.

Tests.—The impurities which may be present in citric acid in consequence of carelessness in its manufacture may be sulphuric acid, calcium, iron, lead, and copper. Minute fragments of metallic lead occasionally are observed adhering to some of the crystals. Sulphuric acid is detected readily in the aqueous solution of citric acid by the white precipitate occurring with barium chloride; iron, by the blue color occasioned by potassium ferrocyanide; and lead and copper, by the black coloration or precipitate resulting from hydrogen sulphide. For the detection of calcium, it is advisable to neutralize the citric acid solution with ammonia, then to acidulate with acetic acid, and add ammonium oxalate, when a white precipitate of calcium oxalate will appear. 5 Cc. of a 10 per cent. solution of the acid neutralized with ammonia should remain clear on the addition of 1 Cc. of ammonium oxalate test-solution (absence of calcium, U. S.). The U. S. P. demands not less than 99.5 per cent. purity, as shown by the following test: If 5 Gm. of citric acid be dissolved in sufficient water to measure 100 Cc., then 34.75 Cc. of this solution should require not less than 24.87 Cc. of normal potassium hydroxide solution (each Cc. corresponding to 4 per cent. of pure citric acid), phenolphthalein being used as an indicator. Mineral impurities may also be tested for in the ash after dissolving it in a little dilute nitric acid.

Tartaric acid is used occasionally as an adulteration, and oxalic acid and various crystallized salts are said to have been employed for the same purpose. Such frauds are accomplished usually by mixing the foreign compounds in a crystalline form with the acid, and it is therefore necessary to employ a larger quantity (say several ounces) of the large and small crystals, to be triturated in a mortar into powder. Many of the salts will be found to be insoluble in alcohol, and may thus be detected, or by the residue left on incinerating a portion of the powder upon platinum-foil. The aqueous solution of the powder is neutralized with ammonia, and then acidulated with acetic acid. Upon adding calcium chloride, oxalic acid, if present, will be precipitated as white calcium oxalate. The clear filtrate, neutralized with ammonia, will deposit in the cold white calcium tartrate if tartaric acid be present, and the filtrate from it will, on boiling, throw down calcium citrate. On dissolving some of the powder in diluted alcohol and adding a concentrated solution of potassium acetate, tartaric acid will yield a white crystalline

precipitate of acid potassium tartrate. Oxalic acid, if present in sufficient quantity, will likewise cause a precipitate with this test. Or a number of crystals of different sizes are placed upon a glass plate in a little potassium hydroxide solution, or preferably a strong solution of potassium acetate: the crystals of citric acid will remain transparent, while the crystals of tartaric acid will become opaque, in consequence of the formation of acid potassium tartrate. The British Pharmacopœia determines the absence of tartaric acid by the following tests: One drop of a solution of ferrous sulphate, then a few drops of hydrogen peroxide solution, and finally an excess of solution of potassium hydroxide, added to an aqueous solution of the acid, no purple or even light violet coloration should result; or 1 Gm. of acid placed in a test-tube with 5 Cc. of solution of ammonium molybdate, 2 or 3 drops of hydrogen peroxide solution being added, should not afford a bluish coloration after the tube has been shaken and placed in boiling water for 10 minutes. (In the latter test, the presence of metallic particles gives rise to a similar coloration.)

Action and Uses.—Citric acid in large quantities produces gastric disorder and diarrhœa. It increases the acidity of the urine and the coagulability of the blood, especially in scurvy, in which disease it is the best remedy we possess for prophylactic and curative treatment. It has been recommended in rheumatic fever, in which condition it may be given in the form of lemon-juice in daily doses of 1 or 2 fluidounces (30–60 Cc.). Lemon-juice has also been employed in catarrhal jaundice. Lemon-juice, in the form of lemonade, is used as a refreshing drink in fevered states. Solutions of citric acid may be employed in the same conditions, but are inferior to the juice obtained from the lemon or lime.

ACIDUM FORMICICUM, *P. G.*—Formic Acid.

Acidum formicarum, Acidum formicum.—Acide formique, Fr.; *Ameisensäure, Formylsäure*, G.

Formula, $CH_2O_2 = HCOOH$. Molecular weight, 45.67.

Historical.—As early as the sixteenth century Brunfels called attention to the acid nature of the vapors from an ant-pile. According to some, J. Wray (1670), according to others, S. Fischer (1670), first showed that the free acid can be obtained by distillation of ants with water vapor. Marggraf (in 1749) distinguished between it and acetic acid.

Occurrence.—Free formic acid occurs in ants, especially in *Formica rufa*, whence its name; also in a number of other insects (*e. g., Bombyx processionea*), and in animal secretions (perspiration, urine). It is found in the leaf-hairs of the nettles, in pine-needles, several volatile oils, and as glyceride in croton oil. It is obtained frequently in small quantity upon distillation of vegetable and animal matter with water vapor. However, it does not always exist as such, but frequently is obtained as a product of decomposition. It has also been found in peat and in several mineral waters (Brueckenau, Prinzhofen, Weilbach).

Formation.—It is obtained by the oxidation of methyl alcohol, by the hydrolysis of hydrocyanic acid, by the saponification of chloroform, by the direct union of CO with KOH at 100° C. (212° F.), etc.

Like all derivatives of methane, formic acid is unique as an acid. It contains both the CHO and COOH groups, and therefore acts both as an aldehyde and an acid. This accounts for its property of precipitating metallic silver from a hot neutral solution of silver nitrate, and calomel from a solution of mercuric chloride, the acid being oxidized to carbonic acid.

Preparation.—Place in a distilling bulb of 150 Cc. capacity 50 Gm. of glycerin and 50 Gm. of crystallized oxalic acid. Immerse a thermometer in the liquid, connect the bulb with a condenser, and heat with a low flame till the thermometer rises slowly to 105° C. (221° F.). Allow to cool to about 50° C. (122° F.), add 50 Gm. more of oxalic acid, and distil again, always over a low flame and slowly, to a temperature of 115° C. (239° F.). The process may be repeated almost indefinitely; the acid coming over in the later distillations is stronger than that in the first. The residue may be used for the preparation of allyl alcohol (Noyes).

Anhydrous acid can be obtained by converting the acid into the lead salt and decomposing this with hydrogen sulphide, or by combining the water of the dilute acid with

anhydrous oxalic acid, allowing the oxalic acid to crystallize, pouring off the formic acid, and distilling. In order to obtain the official acid, the crude acid is rectified by distillation and diluted to the proper strength.

Oxalic acid, when heated by itself, decomposes principally into CO_2, CO, and H_2O, but little formic acid being formed. In glycerin solution, however, formic acid may be obtained in larger amount. The glycerin does not act merely as a physical solvent or regulator of heat, but unites chemically with the oxalic acid: $H_2C_2O_4$ (oxalic acid) + $C_3H_5(OH)_3$ (glycerin) = $C_3H_5(OH)_2COOH$ (glyceryl monoformate) + CO_2 + H_2O. The water formed then saponifies the ester, regenerating glycerin: $C_3H_5(OH)_2COOH$ (glyceryl monoformate) + H_2O = $C_3H_5(OH)_3$ (glycerin) + HCOOH (formic acid). Theoretically, therefore, a small amount of glycerin will suffice to convert an indefinite amount of oxalic acid into formic acid. Practically, the process is limited, owing to secondary changes of the glycerin.

Properties.—A clear colorless volatile liquid with a pungent but not empyreumatic odor and a strongly sour taste. It contains 24 to 25 per cent. of pure acid and has a specific gravity of 1.060 to 1.063 at 15° C. (59° F.). Mixed with solution of basic lead acetate, formic acid yields a white crystalline precipitate of lead formate. Diluted with water (1 : 6) and saturated with yellow mercuric oxide, a clear solution results, which upon heating gradually deposits metallic mercury, indicating the aldehyde character of the acid.

Tests.—When neutralized with potassium hydroxide solution, formic acid should develop neither a pungent nor an empyreumatic odor, showing the absence of acrolein and allyl alcohol. A solution of formic acid (1 : 6) should not be altered by silver nitrate solution (absence of chlorides), nor, after neutralization with ammonia, by calcium chloride solution (absence of oxalic acid), nor by hydrogen sulphide solution (absence of heavy metals).

A solution of 1 Cc. of formic acid in 5 Cc. of water should yield a neutral filtrate after it has been heated on a water-bath with 1.5 Gm. of yellow mercuric oxide, shaking repeatedly, until evolution of gas ceases to take place (absence of other acids). 5 Cc. of official formic acid require for complete neutralization 28–29 Cc. of normal alkali solution, using phenolphthalein as indicator.

Pharmaceutical Preparations.—Spiritus Formicarum, P. G.; *Spiritus formicæ.*—*Spirit of ants*, E.; *Esprit de fourmis*, Fr.; *Ameisengeist, Ameisenspiritus*, G.—A clear colorless liquid, prepared by mixing 2 parts of formic acid, 35 parts of alcohol, and 13 parts of water, all by weight. It has a specific gravity of 0.894–0.898, and if heated with silver nitrate solution the latter assumes a dark color. Owing to the continuous reaction between the formic acid and alcohol, producing ethyl formate, $C_2H_5CHO_2$, this preparation gradually grows weaker in acid. If spirit of ants be shaken with solution of lead subacetate, crystalline lead formate, $Pb(HCO_2)_2$, will separate.

Action and Uses.—Locally applied, formic acid is irritant and rubefacient. If its application is sufficiently prolonged, it vesicates and produces sloughing. When diluted with an equal quantity of water, it is stated to be of advantage in the treatment of neuralgia and rheumatic pains. It may be employed to prevent bedsores, especially in the early stages of paralysis, as it irritates the skin and so increases circulation. It was formerly employed internally, like ammonia, as a rapidly acting diffusible stimulant, and the Spiritus formicarum (P. G.) may be given in the dose of from 20 to 60 minims (1.3–4 Cc.).

ACIDUM GALLICUM, *U. S., Br.*—Gallic Acid.

Trioxybenzoic acid, Dioxysalicylic acid.—Acide gallique, Fr.; *Gallussäure*, G.; *Acido gallico*, It., Sp.

Formula, $HC_7H_5O_5 + H_2O$ or $C_6H_2(OH)_3COOH + H_2O$. Molecular weight, 186.65

Origin.—Gallic acid is found in nutgalls, sumach, uva ursi, and in a number of other astringent plants. It was for a time confounded with tannin, but its distinction from this was recognized by Scheele (1785), who obtained it in a pure state.

Preparation.—Boil 1 part of tannic acid (or 2 parts of coarsely powdered nutgall) with 1 part of sulphuric acid and 5 parts of water, for 15 minutes; strain the mixture while hot, and set the liquid aside so that crystals may form, which are then deprived of

color by re-solution in hot water and filtration through animal charcoal. The filtrate is set aside again to crystallize, and if necessary the treatment with charcoal is repeated.

The above method is indicated in the British Pharmacopœia, and probably is used now altogether, being more expeditious than the following older method: Nutgall, in fine powder, is made into a thin paste with water and exposed to the air in shallow glass or porcelain vessels for a month, occasionally stirring and adding water from time to time to preserve the semifluid consistence. The mixture is then expressed, the liquid rejected, and the residue boiled for a few minutes in distilled water and filtered while hot through animal charcoal. The filtrate is set aside so that crystals may form, which are then dried.

In both cases contact with iron should be avoided, which would impart to the acid a color difficult to remove.

The conversion of the whole amount of tannin into gallic acid is proved readily by testing a small portion of the filtered liquid with solution of isinglass, which should cause no turbidity. The change takes place slowly at a low temperature, and the yield necessarily varies with the amount of tannin present in the galls.

Formation.—The conversion of tannin into gallic acid has been the subject of much controversy, involving numerous researches. It was supposed at first that gallic acid existed ready formed in galls, but the experiments of Pelouze (1833) proved that most of it is formed from the tannin contained therein. The relation of the two compounds to each other appears to have been settled finally by the researches of H. Schiff, Sac and J. Löwe (1871 and 1872), and Etti (1884), according to which, pure tannin is *digallic acid*, an anhydride of gallic acid, the conversion of the former into the latter occurring as follows: $C_{14}H_{10}O_9 + H_2O = 2C_7H_6O_5$; and the sugar observed in the preparation of gallic acid is referable to the glucose which naturally exists in galls, perhaps in combination with digallic acid, and from which tannin is purified with difficulty. Löwe prepared pure tannin from galls, and Schiff succeeded in converting gallic acid into tannin absolutely free from glucose.

Properties.—Gallic acid occurs in fine white or pale fawn-colored silky needles or circular prisms, which have a slightly acid and faint astringent taste, and are inodorous. It is soluble at 15° C. (59° F.) in 100 parts of water and in 5 parts of alcohol; at 25° C. (77° F.) in 83.7 parts of water and in 4.14 parts of alcohol (U. S.); in 3 parts of boiling water and 1 part of boiling alcohol. Also soluble in 40 parts of ether and in 12 parts of glycerin. Very slightly soluble in chloroform, benzene, and benzin. The solution has an acid reaction and gives no precipitate with ferrous sulphate. With ferric salts a bluish-black precipitate is obtained which is easily soluble in acetic acid, and disappears on boiling. Gallic acid dissolves permanently in a solution of potassium citrate to such an extent that, according to F. Long (1881), 15 grains (1 Gm.) of it, with 20 grains (1.3 Gm.) of the citrate, will yield a clear solution in 1 ounce (30 Gm.) of water. At 100° C. (212° F.) it loses 9.5 per cent. of water of crystallization. Heated to between 200° and 215° C. (392° and 419° F.), or, according to Schiff (1879), to about 240° C. (464° F.), it melts, and then yields carbon dioxide gas and a sublimate of pyrogallol, $C_6H_3(OH)_3$, without leaving any residue.

Alkalies added to a solution of gallic acid rapidly color the liquid, which in the presence of very little potassium or sodium hydroxide gradually becomes green, but with an excess is at once yellow, and turns red and brown; little ammonia causes a yellow, and an excess a reddish and red-brown color. Alkali carbonates produce similar colorations, but act less energetically; on the subsequent addition of hydrochloric acid the color is changed to red. If added to a solution of potassium cyanide, gallic acid causes a red coloration (Young's test). Most of its salts, those with the alkalies excepted, are insoluble in water. When perfectly dry they keep unaltered; but in the presence of water, and particularly of alkaline liquids, they speedily are decomposed, becoming brown and black. Solutions of salts of silver, gold, platinum, and the allied metals are reduced gradually by gallic acid and its salts at the ordinary temperature.

Tests.—Resinous substances would be insoluble in boiling water; sugar and dextrin would remain undissolved on treatment with spirit of ether; and mineral admixtures would remain behind upon heating the acid to redness.

Gallic acid may be distinguished from tannic acid as follows: On adding to a cold saturated solution of the acid a little lime water a bluish-white precipitate will form where the test-solution is temporarily in excess, and will disappear on shaking. When the test-

solution has been added in excess, the precipitate no longer dissolves, and the liquid acquires a tint which is blue by reflected and green by transmitted light, or becomes pink on the addition of a large excess of the lime water (U. S.). Gallic acid solutions do not precipitate solutions of the alkaloids, gelatin, tartar emetic, albumin, and starch. Fehling's Solution is not reduced by gallic acid.

Action and Uses.—When locally applied, gallic acid acts as a mild astringent, but does not cause coagulation of the blood, for which reason it is not used locally in the control of hemorrhage. When administered internally, the drug is rapidly absorbed and eliminated by the kidneys as gallic acid. It is stated that it decreases the secretion of sweat and of urine, and that it does not cause constipation.

When taken internally, gallic acid produces constriction of the bloodvessels, and in this manner lends itself to the control of capillary and arteriole hemorrhage.

Gallic acid has been used with asserted benefit in hæmaturia, purpura, hæmoptysis, and menorrhagia. It has been employed successfully in local sweating of the hands and feet, in the night-sweats of phthisis, and when combined with opium is of value in diabetes insipidus and mellitus. It may do good in pyrosis, bronchitis with profuse expectoration, epistaxis, and in intestinal and other forms of hemorrhage. In both acute and chronic Bright's disease the drug causes a material decrease in the albumin in the urine.

Locally applied in the form of an ointment, it has been used in the treatment of external hemorrhoids and in chronic ulcers and sores. It has also met with favor in the treatment of psoriasis and alopecia.

The dose for internal use is from 5 to 20 grains (0.30–1.30) Gm.), repeated several times daily according to the urgency of the case.

ACIDUM GLYCEROPHOSPHORICUM.—Glycerophosphoric Acid.

Acidum glycerinophosphoricum.—Glycerinophosphoric acid, Phosphoglyceric acid, Glycerin acid phosphate, E.; *Glycerinphosphorsäure, Saurer Phosphorsäureglycerinester,* G.

Formula, $C_3H_5(OH)_2H_2PO_4$ or $C_3H_5(OH)_2O.PO(OH)_2$. Molecular weight, 170.78.

Occurrence.—Glycerophosphoric acid is met with in blood, flesh, the brain, and the nerves. It also occurs together with cholin as a result of the splitting up of lecithin.

Preparation.—Absolute glycerophosphoric acid is very unstable, and all efforts to produce a concentrated solution of the same have resulted in decomposition of the acid into glycerin and phosphoric acid. The commercial article sold as glycerophosphoric acid is a 20 per cent. aqueous solution of the ester. It may be obtained as follows: Glacial phosphoric acid (metaphosphoric acid) is dissolved gradually in an equal weight of 95 per cent. glycerin with aid of a moderate heat, and the solution then heated to 110° C. (230° F.) on a paraffin-bath for several hours. Water is split off and the following reaction takes place: $C_3H_5(OH)_3 + HPO_3 = C_3H_5(OH)_2H_2PO_4$. A tenacious mass results, which is dissolved, while still warm, in cold water and an excess of milk of lime or solution of barium hydroxide added. The mixture is filtered, the excess of calcium or barium hydroxide removed by a current of carbon dioxide, and again filtered. The filtrate is concentrated in a vacuum apparatus and precipitated by addition of alcohol or evaporated to dryness. The glycerophosphate thus obtained is freed from adhering glycerin by washing with alcohol, redissolved in water, and decomposed by addition of a previously calculated quantity of diluted sulphuric acid, the precipitated calcium or barium sulphate being removed by filtration and the acid liquid evaporated to the proper density.

Properties.—When freshly prepared, glycerophosphoric acid is a clear colorless liquid having the specific gravity 1.125; on keeping, it gradually assumes a yellow color and decomposes slowly in the cold, more rapidly when heated, into glycerin and ordinary phosphoric acid. It has a decided acid taste and reaction, and is readily miscible with water and alcohol. Being a dibasic acid, it is capable of forming both normal and acid salts; the former are soluble in water, insoluble in alcohol, and generally have an alkaline reaction. If lead acetate be added to an aqueous solution of the glycerophosphates, the corresponding lead salt is precipitated, which is readily soluble in nitric acid, but with difficulty in acetic acid. The usual reagents for phosphoric acid, such as ammonium molybdate, uranium acetate, and magnesia mixture, do not affect a solution of glycerophosphates in the cold. If glycerophosphates be boiled with mineral acids, the liberated

acid breaks up into glycerin and ordinary phosphoric acid. When heated to redness they are converted into pyrophosphates.

The glycerophosphates of calcium, potassium, sodium, lithium, iron, and quinine have been introduced into medicine. They are discussed under the respective bases.

Action and Uses.—Glycerophosphoric acid is not employed in medicine as such; but its salts, especially that of sodium, have been used quite largely in the treatment of certain constitutional conditions. (For action and uses, see CALCII GLYCEROPHOSPHAS.)

ACIDUM HYDRIODICUM DILUTUM, *U. S.*—Diluted Hydriodic Acid.

Acid hydroiodique dilué, Fr.; *Verdünnte Jodwasserstoffsäure*, G.

Formula, HI. Molecular weight, 126.9.

A solution of hydriodic acid, containing not less than 10 per cent. of the absolute acid and about 90 per cent. of water. It should be kept in amber-colored glass-stoppered bottles, protected from light.—U. S.

Preparation.—Potassium iodide, 135 Gm.; potassium hypophosphite, 10 Gm.; tartaric acid, 136.5 Gm.; distilled water, diluted alcohol, of each a sufficient quantity to make 1000 Gm. Dissolve the potassium salts in 250 Cc. of distilled water with the aid of heat, and the tartaric acid in 400 Cc. of diluted alcohol. Having poured the solution of tartaric acid into a bottle of about 1000 Cc. capacity, add the solution of the potassium salts and shake the mixture briskly. Set the bottle into a bath of ice-water for several hours and, having placed a pledget of cotton tightly in the throat of a funnel, transfer the contents of the bottle to the funnel. When all the liquid has passed through, wash the bottle and crystalline precipitate with diluted alcohol in successive small portions until 1000 Gm. of clear filtrate have been obtained. Evaporate the liquid at a moderate temperature, on a water-bath, until all of the alcohol has been dissipated, and add sufficient distilled water to make the product weigh 1000 Gm.—U. S.

In the above process the potassium iodide and hypophosphite are decomposed by the tartaric acid, liberating hydriodic and hypophosphorous acids, acid potassium tartrate being formed at the same time, which is precipitated, thus: $KI + KPH_2O_2 + 2H_2C_4H_4O_6 = HI + HPH_2O_2 + 2KHC_4H_4O_6$. The presence of alcohol aids in the removal of the acid potassium tartrate, as does also the application of cold. Upon evaporation of the filtrate for removal of the alcohol, it assumes a yellowish color when concentrated, but no iodine is liberated, and the liquid again becomes colorless when diluted with distilled water.

Properties.—Diluted hydriodic acid is a clear colorless liquid without odor and having an acid taste. It has a specific gravity of about 1.106 at 25° C. (77° F.), and is miscible in all proportions with water and alcohol. To blue litmus-paper it shows a strong acid reaction. On distilling diluted hydriodic acid, water with some weak acid first passes over; at the temperature of 127° C. (260.6° F.) an acid of 57.5 per cent. distils over unchanged. Silver nitrate test-solution causes a yellow, curdy precipitate, insoluble in nitric acid, almost insoluble in ammonia-water, but soluble in solutions of sodium thiosulphate and potassium cyanide. If a few drops of ferric chloride test-solution or chlorine-water be added to the acid, diluted with twice its volume of water, iodine will be liberated and impart to the solution a reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color.—U. S.

Tests.—Diluted hydriodic acid should not become colored on keeping. Barium chloride test-solution should not produce a turbidity or precipitate (absence of sulphuric acid). The acid should not be rendered turbid by addition of potassium sulphate test-solution (absence of barium). Diluted hydriodic acid, when evaporated to dryness on a water-bath of boiling water and then heated to 115° C. (239° F.), should not leave more than 1 per cent. of residue. 10 Cc. of the diluted acid warmed to about 50° C. (122° F.) should not be colored or rendered turbid by the addition of an equal volume of fresh hydrogen sulphide test-solution after standing stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). If 5 Cc. of diluted hydriodic acid be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and then evaporated to dryness on a bath of boiling water, the residue should not respond to the modified Gutzeit's test for arsenic (see under ARSENI TRIOXIDUM). Into a flask provided with a well-fitting stopper introduce 2.54 Gm. of diluted hydriodic acid, diluted with

50 Cc. of distilled water, followed by 25 Cc. of tenth-normal silver nitrate solution, 5 Cc. of ferric ammonium sulphate test-solution, and 3 or 4 Cc. of nitric acid (free from nitrous compounds), then securely stopper the flask and shake it well. Not more than 5 Cc. of tenth-normal potassium sulphocyanate solution should then be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate solution consumed by the diluted hydriodic acid corresponding to 0.5 per cent. of absolute hydriodic acid).—U. S.

Hydriodic acid was first recognized by Clement and Desormes in 1813 and investigated the same year by Gay-Lussac. The absolute acid may be prepared by the action of iodine on phosphorus in the presence of water, used in the proportions of 15, 1, and 4 respectively. The flask containing the mixture is connected with a condenser and a receiving flask partly filled with water. Upon heating, the following reactions occur: $P + I_3 = PI_3$; $PI_3 + 3H_2O = 3HI + H_3PO_3$; the gaseous acid being absorbed by the water in the flask. Solutions of hydriodic acid decompose readily, especially when exposed to light, which may be prevented by the presence of free hypophosphorous acid. The official diluted acid (containing about 0.63 per cent. of absolute hypophosphorous acid) has been found to keep perfectly for over 6 months in diffused light.

Absolute hydriodic acid is a colorless, irrespirable, and uninflammable gas of 4.44 specific gravity, and having an odor resembling hydrochloric acid. The most concentrated solution obtainable by distillation contains 57.75 per cent. of HI, has a specific gravity of 1.708, and boils at 127° C. (260.6° F.).

Action and Uses.—This preparation contains about ten times the amount of hydriodic acid as does the Syrupus Acidi Hydriodici. It produces less disorder of the stomach than the iodides, and like them is employed for the alterative effect of the iodine present. If discolored by the presence of free iodine it should not be administered, as it may produce severe gastric irritation. It is considered of especial value in scrofulosis in children. The dose is from 5 to 40 minims (0.30–2.6 Cc.).

ACIDUM HYDROBROMICUM DILUTUM, *U. S., Br.*—Diluted Hydrobromic Acid.

Acidum Hydrobromicum, P. G.; *Acide hydrobromique dilué*, Fr.; *Verdünnte Bromwasserstoffsäure, V. Hydrobromsäure*, G.

Formula, HBr. Molecular weight, 80.36.

A liquid composed of 10 per cent. of absolute hydrobromic acid and about 90 per cent. of water. It should be preserved in amber-colored glass-stoppered bottles and protected from light.—U. S.

Origin.—Hydrobromic acid was discovered by Balard (1826). It is formed by the direct union of its elements at a red heat, by the decomposition of hydrogen sulphide and other hydrogen compounds by bromine, by the action of bromine in the presence of water upon the lower oxides of sulphur, phosphorus, arsenic, and other elements, and by the action of water upon the sulphur, phosphorus, and other compounds of bromine.

Preparation.—Markoe (1875) recommended the following procedure: 1 pound of phosphorus is spread over the bottom of a 1-gallon jar, covered with water, and the jar half-filled with ice, after which a large funnel is inserted into the throat of the jar, a funnel-tube adjusted so as to reach a short distance above the phosphorus, and the jar surrounded with ice. 3 or 4 pounds of bromine may now be added very slowly through the funnel-tube, care being taken to prevent accumulation in the jar of uncombined bromine, which would give rise to an explosion when reacting with the phosphorus. The two elements unite to form phosphorus pentabromide, PBr_5; and this, reacting with water, forms phosphoric and hydrobromic acids; $PBr_5 + 4H_2O$ yields $H_3PO_4 + 5HBr$. After the reaction is completed, the excess of phosphorus is removed, and the aqueous liquid distilled until hydrobromic acid ceases to come over. The syrupy residue left in the retort, when properly diluted, is utilized as phosphoric acid.

Fothergill's formula is an adaptation of that of D. C. Wade (1875). An acid of the strength required by the U. S. Pharmacopœia, but containing small quantities of potassium bitartrate and bromide, may be prepared extemporaneously by dissolving 8 parts of potassium bromide and 10 parts of tartaric acid, each in 25 parts of distilled water, mixing the solutions, cooling the mixture, and stirring it well; after the potassium bitartrate has precipitated, the whole is thrown upon a small filter, and the vessel and precipitate are washed with 10 parts of ice-cold water. The potassium bitartrate may be

removed more completely by adding double the volume of strong alcohol to the mixture, and letting it stand some time, filtering, and recovering the alcohol by distillation.

Hydrobromic acid, like hydriodic acid, cannot be made by distilling bromides with strong sulphuric acid, owing to decomposition of the acid into free bromine. This difficulty has been overcome in a method proposed by Dr. Squibb (1878), as follows: 7 parts by weight of sulphuric acid, specific gravity 1.838 at 15.6° C. (60° F.), are added to 1 part of water, and the mixture allowed to cool, when it is slowly, and with constant stirring, added to a hot solution of 6 parts of potassium bromide in 6 parts of water. A decomposition into hydrobromic acid and potassium sulphate will take place; $2KBr + H_2SO_4$ yields $2HBr + K_2SO_4$. On setting the mixture aside for 24 hours, the salt crystallizes, the liquid is poured off into a retort, and the crystalline mass broken up, transferred to a funnel, and washed with 2 parts of cold water to recover adhering hydrobromic acid. The washings likewise are poured into the retort, which is placed upon a sand-bath or set upon wire gauze, and the whole then is distilled nearly to dryness. The distillate, which weighs about 10 parts, is assayed with normal sodium hydroxide solution, and then diluted with distilled water so as to contain 34 per cent. of HBr. When of this strength, the acid represents one-half the bromine strength of an equal weight of potassium bromide, and should be dispensed only as *acidum hydrobromicum concentratum.*

The following other methods may be employed to prepare hydrobromic acid solutions: Exact precipitation of barium bromide in solution with sulphuric acid and distillation of the filtrate: $(BaBr_2 + 2H_2O) + H_2SO_4 = BaSO_4 + 2HBr + 2H_2O$. Distillation of potassium bromide with phosphoric acid, specific gravity 1.304 (W. Grüning, 1883): $KBr + H_3PO_4 = HBr + KH_2PO_4$. Decomposition of hydrogen sulphide by bromine, as in case of hydriodic acid, and subsequent distillation: $H_2S + Br_2 = 2HBr + S$. By action of bromine on organic bodies, such as benzene, for example: $C_6H_6 + 2Br_2 = C_6H_4Br_2 + 2HBr$. Large quantities of the gaseous HBr are obtained in this manner in the chemical industries as a by-product. The acid is converted into barium bromide, from which an aqueous solution is obtained in the manner given above.

Properties.—Diluted hydrobromic acid has the specific gravity 1.076 at 25° C. (77° F.) (U. S.) and contains 10 per cent. of HBr (U. S., Br.). The hydrobromic acid of the German Pharmacopœia is $2\frac{1}{2}$ times as strong as the preceding and is not officially designated as diluted acid. Pure hydrobromic acid is a colorless gas of a pungent and irritating odor, and produces dense white fumes in a moist atmosphere. The specific gravity of the gas is 2.797 (air = 1), and 1 liter at 0° C. (32° F.) and 760 Mm. weighs 3.6167 Gm. Its aqueous solutions are colorless, odorless, limpid liquids of a strongly acid taste, which remain colorless on exposure to air when dilute, but strong solutions turn yellow. Dr. Squibb determined the acid of the strength suggested by him to have the specific gravity 1.274 at 15.6° C. (60° F.), and to contain 34 per cent. of HBr. When heated, water and a weak acid distil over, and when the temperature reaches 126° C. (258.8° F.) an acid remains which has the specific gravity 1.490 and contains 47.8 per cent. of HBr. This strong acid may be distilled unchanged.

Hydrobromic acid liberates bromine on the cautious addition of chlorine water or of nitric acid, the bromine being soluble, with a yellow or orange-red color, in chloroform, ether, and carbon disulphide; and such a solution, agitated with starch paste, imparts to the latter a yellow color; excess of chlorine water will destroy the color.

The density of aqueous hydrobromic acid at 15° C. (59° F.), according to Biel (1881), is as follows:

Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.
1	1.0082	11	1.085	21	1.172	31	1.270	41	1.388
2	1.0155	12	1.093	22	1.181	32	1.281	42	1.401
3	1.0230	13	1.102	23	1.190	33	1.292	43	1.415
4	1.0305	14	1.110	24	1.200	34	1.303	44	1.429
5	1.0380	15	1.119	25	1.209	35	1.314	45	1.444
6	1.0460	16	1.127	26	1.219	36	1.326	46	1.459
7	1.0530	17	1.136	27	1.229	37	1.338	47	1.474
8	1.0610	18	1.145	28	1.239	38	1.350	48	1.490
9	1.0690	19	1.154	29	1.249	39	1.362	49	1.496
10	1.0770	20	1.163	30	1.260	40	1.375	50	1.513

Tests.—The acid should not become colored on keeping. If copper sulphate test-solution be added to the acid, a deep-red color is produced upon the addition of sulphuric acid. It yields a yellowish-white precipitate with silver nitrate solution, which is nearly insoluble in *dilute* ammonia-water; silver chloride, however, is readily soluble in the latter. If 10 Cc. of the acid be evaporated and heated to 110° C. (230° F.), no appreciable residue should remain (limit of non-volatile impurities). Barium chloride solution should not produce a precipitate or turbidity (absence of sulphuric acid). 10 Cc. of the acid should not be rendered turbid by 1 Cc. of potassium sulphate test-solution (absence of barium). 10 Cc. of the acid warmed to 50° C. (122° F.) should not be colored or rendered turbid by the addition of an equal volume of fresh hydrogen sulphide test-solution after standing stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). 2 Cc. of chloroform shaken with 10 Cc. of the acid should remain colorless (absence of free bromine), and by subsequent addition of chlorine-water previously diluted with an equal volume of water, drop by drop, with shaking, the chloroform should be colored orange, with no trace of violet (absence of iodine). 5 Cc. of the acid should not respond to the modified Gutzeit's test for arsenic (see under ARSENI TRIOXIDUM). If 0.5 Cc. of the acid, 10 Cc. of water, 8 Cc. of silver nitrate solution, and 6 Cc. of ammonium carbonate test-solution be mixed and digested for 10 minutes on a boiling water-bath, then cooled and filtered, the filtrate, acidified with nitric acid, should not become more than slightly opalescent (limit of hydrochloric acid and chlorides). If 10 Gm. of the acid be diluted with water to 100 Cc., and if to 8.04 Cc. of this solution, after exact neutralization with dilute ammonia-water (litmus as indicator), there be added 3 drops of potassium chromate test-solution, not less than 10 Cc. of decinormal silver nitrate should be required to produce a permanent red color in the liquid (each Cc. representing 1 per cent. of absolute acid). 0.804 Gm. of the acid are used in the titration, and 1 Cc. of the silver solution precipitates 0.00804 Gm. of HBr, which is 1 per cent. of the weight taken for titration. The reaction is $HBr + AgNO_3 = AgBr + HNO_3$. The solution is made neutral in order that the chromate indicator may be used to show when just enough silver solution has been added. In the Br. P. 4 Gm. of the acid should require 49.8 Cc. of the volumetric silver solution. 5 Cc. of the official German acid should require 18.7 Cc. of normal alkali for neutralization.

Action and Uses.—In concentrated form, hydrobromic acid is a caustic poison, producing symptoms resembling those caused by poisoning by hydrochloric acid. Internally, in its dilute form, the drug may be employed with some benefit in those conditions which usually are relieved by the bromides (see Potassii Bromidum). Because of its irritating properties, it cannot, as a rule, be given in quantities sufficiently large to produce any marked result. It is stated that it possesses the peculiar property of preventing and relieving tinnitus aurium, and for this purpose has been exhibited with quinine and the salicylates. As these drugs themselves frequently cause gastric distress, its combination with them at times may prove of decided disadvantage.

Diluted hydrobromic acid is usually given in the dose of from 1 to 2 fluidrachms (4–8 Cc.) well diluted with sweetened water.

ACIDUM HYDROCHLORICUM, *U. S., Br., P. G.*—Hydrochloric Acid.

Acidum muriaticum s. hydrochloratum s. chlorhydricum.—*Muriatic acid*, E.; *Acide chlorhydrique s. muriatique*, Fr.; *Salzsäure, Chlorwasserstoffsäure*, G.; *Acido cloridico*, F. It., Sp.

Formula, HCl. Molecular weight, 36.18.

The acid of the U. S. Pharmacopœia, of 1.158 specific gravity at 25° C. (77° F.) and containing 31.9 per cent. of HCl, is practically identical with that of the British, which contains 31.79 per cent. of HCl.

Origin.—Hydrochloric acid occurs in the uncombined state among the gases emitted by active volcanoes, and in combination its radical, chlorine, is found in numerous minerals, prominent among which is sodium chloride, or common salt, which is also one of the most important constituents of sea water and the source of nearly all the hydrochloric acid of commerce. The acid was obtained in the fifteenth century by Basilius Valentinus, and was described as *spirit of salt*, a name which is used occasionally even at the present time. The correct composition of hydrochloric acid was proved by Humphry Davy (1810).

Preparation.—The acid is made by the action of concentrated sulphuric acid on sodium chloride: $2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$. It escapes as a gas from the retort, and is caught in pure water in a cooled receiver. Enormous quantities of the

acid are produced in the Le Blanc soda factories, where common salt and sulphuric acid are heated in large horizontal cylinders in order to obtain sodium sulphate or "salt cake," which is the first step in the manufacture of sodium carbonate. Formerly the acid was allowed to escape into the air, but a law was passed prohibiting this, so that now the acid is caught in water and furnishes practically all the crude acid of commerce The acid is a source of revenue to the soda industries, and offers the anomalous instance of an evil thing being turned to great profit by the very law which was directed against it. The acid from the soda works usually has a lighter or darker yellow color, due to a small quantity of ferric chloride. It finds application in cases where great purity is not essential. Pure acid is prepared on a large scale by distilling pure salt and sulphuric acid from a glass retort and catching the acid in pure water.

To prepare the acid in the laboratory, it is better to choose quantities so that acid sodium sulphate is formed—thus, $NaCl + H_2SO_4 = NaHSO_4 + HCl$—because a lower temperature is required. 3 parts of dry salt require a trifle over 5 parts of concentrated sulphuric acid. The acid should be diluted with about ½ its weight of water. The crude acid may also be purified by distillation.

Dry gaseous hydrochloric acid may be prepared by dropping concentrated sulphuric acid from a dropping funnel into a flask containing fuming hydrochloric acid, fitted with a tube leading to a wash-bottle filled with concentrated sulphuric acid. The gas may also be led into distilled water to form a solution of pure acid.

Arsenic-free Hydrochloric Acid.—Almost every specimen of hydrochloric acid on the market, unless very carefully purified, contains small quantities of arsenic. This is particularly true in the case of the acid made by using European sulphuric acid, which is made from iron pyrites, and this usually contains arsenic. The American sulphuric acid is made chiefly from sulphur, and is much purer and freer from arsenic.

For toxicological purposes, hydrochloric acid absolutely free from arsenic is required. It may be prepared thus: In a glass-stoppered retort place 1000 Cc. of "pure" fuming hydrochloric acid and 30 Gm. of ferrous chloride (dry); heat until fumes cease to come off and a watery distillate begins to come over. Collect this distillate until about 150 Cc. remain in the retort. The acid is about 20 per cent. strong, and contains only a trace of ferric chloride, which does not interfere in tests for arsenic. The arsenic impurity is removed at the beginning as volatile arsenous chloride. Arsenic-free acid should not be kept a long time in glass vessels, since glass usually contains arsenic, which will recontaminate the acid (Hager's *Handbuch*, 1899). Traces of arsenic may also be removed from strong hydrochloric acid by precipitating it with stannous chloride and redistilling the clear solution (Bettendorff, *Zeit. für Chem.*, (2) 5, p. 492).

Fuming Hydrochloric Acid.—The acid known in commerce by this name has a specific gravity of 1.195 and contains 38.2 per cent. of HCl; fumes strongly in air and is colorless. It is used in analytical and synthetical processes and for preparing arsenic-free and gaseous hydrochloric acid.

Crude Hydrochloric Acid.—This is the yellowish impure fuming acid of commerce, obtained as a by-product in large chemical industries, chiefly in the Le Blanc soda process; specific gravity 1.16–1.17, strength 30–33 per cent. The impurities are iron, alumina, sulphuric and sulphurous acids, chlorine, arsenic.

Properties.—1. Hydrochloric Acid Gas.—It is colorless, has a pungent, acid, suffocating odor, and when inhaled is highly irritating, though less so than chlorine. Its specific gravity is 1.2844 (Thomson). The weight of 1 liter at 0° C. (32° F.) and 760 Mm. pressure is 1.6352 Gm. It strongly reddens blue litmus-paper, does not support combustion, and in contact with the atmosphere produces grayish-white fumes by condensing the moisture of the air. It may be condensed into a colorless liquid by a pressure of 1 atmosphere and a refrigerating mixture of solid carbon dioxide and ether. This liquid does not congeal at —110° C. (—166° F.), and at 10° C. (50° F.) exerts a pressure equal to 40 atmospheres. Its composition is HCl, or equal volumes of hydrogen and chlorine united without condensation.

2. Official Hydrochloric Acid.—It is a colorless liquid, having the specific gravity 1.158 at 25° C. (77° F.), U. S., 1.160, Br., 1.124, P. G., and emitting white vapors in contact with the air. It gives with silver nitrate a white curdy precipitate, which is soluble in ammonia and insoluble in nitric acid. The strength of the acid is determined by diluting 10 Gm. with water to 100 Cc. and titrating 36.2 Cc. (36.18 Cc.) of this solution (representing 3.62 Gm. of the acid) with normal alkali solution, using phenolphthalein as indicator. 31.9 Cc. of the normal alkali should be required, each

Cc. corresponding to 1 per cent. of absolute acid. 1 Gm. diluted with water should require 8.7 Cc. normal alkali (Br.). 0.1 Gm. should require, for complete precipitation, 8.7 Cc. of decinormal solution of silver nitrate (Br.). Pure hydrochloric acid of the German Pharmacopœia is required to have the density 1.124 and to contain 25 per cent. of HCl; and 5 Cc. of the acid will therefore require 38.5 Cc. of normal alkali solution.

Water absorbs at 0° C. (32° F.), the barometer being 760 Mm., 503 volumes, at 20° C. (68° F.) 460 volumes, of hydrochloric acid gas. The concentrated acid, on being heated, loses gas, becoming weaker on boiling until, at the barometric pressure given before, it has reached the specific gravity 1.098 at 25° C. (77° F.), contains 20.13 per cent. of HCl, and distils at 110° C. (230° F.) unchanged, leaving no residue if the acid was perfectly pure. On boiling a weaker acid it becomes stronger, the final density depending on the atmospheric pressure.

Hydrochloric acid of the specific gravity 1.01 at 25° C. (77° F.) contains, according to E. Davy, 2.02 per cent. of gas, and for every additional 2.02 per cent. increases in density at the ratio of 0.01, so that an acid of 1.10 specific gravity contains 20.20 per cent., and if of specific gravity 1.19 contains 38.38 per cent. of gas. These figures differ little from those ascertained by A. Ure.

The following table, which is incorporated in the U. S. Pharmacopœia, refers only to chemically pure acids. The percentage of real acid in the commercial acids, particularly when they are concentrated, is always less than that given in the table:

Per cent. hydrochloric acid.	Specific gravity — 25° C. / 25° C.	Specific gravity — 15° C. / 15° C.	Correction of specific gravity for 1° C.[1]	Fractional per cent.[2]	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc. normal KOH.

Note.—To find the per cent. of chlorine, multiply the per cent. of HCl by 0.9724.

To find the weight in grammes of HCl in 100 Cc., multiply the specific gravity by the per cent. of HCl.

To find the volume per cent. of official Hydrochloric Acid, multiply the "normality" by 9.823. For the volume per cent. of official diluted Hydrochloric Acid, multiply the "normality" by 34.60.

[1] Add if the temperature is above, subtract if the temperature is below, 25° C.

[2] Corresponding with a difference in specific gravity of 0.0001.

Impurities and Tests.—By evaporating 10 Cc. of the acid and drying at 110° C. (230° F.), no appreciable residue should remain (limit of non-volatile matter). If to 5 Cc. of the acid, diluted with an equal volume of water, 1 Cc. of chloroform be added, and if chlorine-water previously diluted with an equal volume of water be then added, a drop at a time, with constant agitation, the chloroform should remain free from any yellow, orange, or violet color (absence of bromine or iodine). On agitating a mixture of 1 Cc. of the acid, 5 Cc. of water, 1 Cc. of potassium iodide test-solution, and 1 Cc. of chloroform, the chloroform should be free from any violet coloration (absence of free chlorine or bromine). 5 Cc. of the diluted acid (1 in 10) should not respond to the modified Gutzeit's test for arsenic (see under ARSENI TRIOXIDUM). If 1 Cc. of the acid be diluted with 5 Cc. of water, and a few drops of barium chloride test-solution be added, no precipitate or turbidity should appear within one hour (absence of sulphuric acid or sulphates), nor should a few drops of tenth-normal iodine solution produce a turbidity in this mixture (absence of sulphurous acid). 10 Cc. of the diluted acid (1 in 20), warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of fresh hydrogen sulphide test-solution after standing stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals).

Acidum Hydrochloricum Dilutum, U. S., Br., P. G.—*Acidum muriaticum dilutum.—Diluted hydrochloric acid, Diluted muriatic acid,* E.; *Acide chlorhydrique dilué,* Fr.; *Verdünnte Salzsäure,* G.

Preparation.—Diluted hydrochloric acid is prepared by mixing 100 Gm. of hydrochloric acid with 219 Gm. of distilled water (U. S.). Or 10 parts of the acid may be mixed with 21.9 parts of water, all by weight. The British Pharmacopœia directs that to 350.1 Gm. (or 3063 grains) of hydrochloric acid sufficient distilled water be added, so that the mixture after shaking shall measure 1000 Cc. (or 1 Imperial pint) at 15.5° C. (60° F.). The German diluted hydrochloric acid is made by mixing equal parts by weight of 25 per cent. hydrochloric acid and water.

Properties.—The diluted acid has the same properties as the strong acid, except that it does not fume and is without odor. It contains 10 per cent. of absolute HCl (U. S.), 10.58 per cent. (Br.), 12.5 per cent. (P. G.), and has the specific gravity 1.049 at 25° C. (77° F.) (U. S.), 1.052 (Br.), 1.061 (P. G.). The amount of normal sodium hydroxide solution required for neutralization is 10 Cc. for 3.62 Gm. of the diluted acid (U. S.), and 2.9 Cc. for 1 Gm. of the latter (Br.). The diluted acid should conform to all the reactions and tests of the strong acid.

Action and Uses.—When applied to the skin in concentrated form, hydrochloric acid produces a blister, and if allowed to remain sufficiently long destroys the tissue. It first whitens mucous membranes, but finally produces necrosis with sloughing.

When taken internally in diluted form, the drug is said to increase the peristaltic action of the stomach and to prevent lactic acid fermentation. It acts as a gastric antiseptic and exists in the normal gastric juice in the strength of 0.2 per cent., aiding in the conversion of pepsinogen into pepsin and of proteids into peptones. Hydrochloric acid may do good in certain forms of indigestion, especially in those conditions in which it is absent from the gastric juice, as in the low fevers. It will be found of great service in many cases of enteric fever. In chronic gastric catarrh with atony of the tubules and in gastric cancer it may be administered with success. It has been recommended in syphilis, phosphaturia, and in intestinal indigestion with diarrhœa. As a caustic, concentrated hydrochloric acid may be employed in the removal of small epithelial growths.

Poisonous doses of hydrochloric acid produce a whitening of the mucous membrane of the mouth, violent pain in the œsophagus, stomach, and intestines, corrosion or perforation of the wall of the stomach, with consequent peritonitis. The patient becomes restless, complains of thirst, and attempts to vomit. There may be collapse, the temperature becoming subnormal and the pulse running and thready. Large quantities of mild alkalies, such as magnesia, soap, or wall-plaster, should promptly be given. Mucilaginous drinks, eggs, milk or bland oils, and opium may be used for relief of the pain. The application of external heat to maintain the bodily temperature and the free use of stimulants are indicated should collapse occur.

Hydrochloric acid may be given in the dose of from 5 to 10 minims (0.3–0.6 Cc.)

largely diluted with water and taken through a glass tube. Immediately after its ingestion the mouth should be rinsed with a solution of sodium bicarbonate. It is usually given in the form of the dilute acid, in the dose of 5 to 30 minims (0.30–2 Cc.).

ACIDUM HYDROCYANICUM DILUTUM, *U. S.*, *Br.* — Diluted Hydrocyanic Acid.

Acidum hydrocyanatum s. borussicum.—Prussic acid, E.; *Acide cyanhydrique s. hydrocyanique,* Fr.; *Cyanwasserstoffsäure, Blausäure,* G.; *Acido cianhidrico,* Sp.

Formula, HCN, old style HCy. Molecular weight, 26.84.

The official diluted acid of the U. S. and Br. pharmacopœias contains 2 per cent. of absolute hydrocyanic acid; the French preparation contains only 1 per cent., while the Spanish contains 10 per cent. Hydrocyanic acid is not recognized at all in the German Pharmacopœia.

Origin.—Hydrocyanic acid was discovered by Scheele (1782); Berthollet (1803) ascertained it to be a compound of hydrogen, carbon, and nitrogen; and Gay-Lussac (1815) succeeded in analyzing it and in isolating the radical *cyanogen,* CN, or, more correctly, $(CN)_2$. The acid has been found in the root of *Jatropha Manihot,* and in the bark, leaves, flowers, and seeds of many shrubs and trees belonging to the suborders *Amygdaleæ* and *Pomeæ* of the order *Rosaceæ.* It occurs in the free state only in some of the more juicy parts of these plants, but a larger quantity is formed on macerating the parts indicated in cold water, when the amygdalin contained therein is split by the action of emulsin or a similar ferment into sugar, oil of bitter almond, and hydrocyanic acid; $C_{20}H_{27}NO_{11}$ (amygdalin) $+ 2H_2O$ yields $2C_6H_{12}O_6$ (glucose) $+ C_7H_6O$ (oil of bitter almond) $+$ HCN (hydrocyanic acid). It is found likewise among the products of the reaction of nitric and nitrous acids upon many organic compounds, and of gaseous ammonia upon incandescent charcoal. For medicinal purposes it is prepared mostly by the decomposition of potassium ferrocyanide by means of sulphuric acid. It may also be prepared extemporaneously by the following process:

Preparation.—Silver cyanide, 6 Gm.; diluted hydrochloric acid, 15.54 Cc.; distilled water, 44.10 Cc. Mix the diluted hydrochloric acid with the water, add the silver cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid.—U. S. 50 grains of silver cyanide may be added to a mixture of 138 grains of diluted hydrochloric acid and 355 grains of distilled water, and the resulting solution, after filtration, will correspond to the official acid. The hydrochloric acid decomposes the silver cyanide, forming hydrocyanic acid and insoluble silver chloride, thus: $AgCN + HCl = HCN + AgCl$. 1 grain (1 Gm.) of silver cyanide will yield 0.2019 grain (0.2019 Gm.) of absolute hydrocyanic acid. The Br. P. does not give a process for making the official acid, but states that it may be made by the interaction of diluted sulphuric acid and potassium ferrocyanide.

On mixing diluted sulphuric acid with a solution of potassium ferrocyanide in the cold, only one-half of the latter salt is decomposed, with the formation of potassium sulphate and hydroferrocyanic acid; thus, $K_4Fe(CN)_6$ (potassium ferrocyanide) $+ 2H_2SO_4$ yields $2K_2SO_4 + H_4Fe(CN)_6$ (hydroferrocyanic acid). This last compound may be obtained by adding ether to the mixture, when the acid will be separated as a whitish powder or pearly scales. On the application of heat to the mixture, this acid reacts with the remaining potassium ferrocyanide and sulphuric acid, yielding hydrocyanic acid, which distils over, potassium sulphate, which remains in solution, and ferrocyanide of iron and potassium (Everitt's salt), which precipitates as a white powder, rapidly turning green, and finally blue, in the presence of oxygen. The reaction may be explained as follows: $H_4Fe(CN)_6 + K_4Fe(CN)_6 + H_2SO_4 = 6HCN$ (hydrocyanic acid) $+ K_2SO_4 + K_2Fe(FeC_6N_6)$ (Everitt's salt).

Properties.—Anhydrous hydrocyanic acid is a colorless mobile liquid which congeals at —15° C. (5° F.) to feathery crystals, has the density 0.697 at 18° C. (64.4° F.), boils at 26.5° C. (79.7° F.), and when ignited burns with a slightly luminous flame to carbonic anhydride and nitrogen. It has a strong odor, resembling that of oil of bitter almond, and is extremely poisonous. It is the hydride of the radical cyanogen, and its composition is expressed by the formula HCN. It reddens litmus-paper slightly and transiently, and with alkalies yields crystallizable salts having a strongly alkaline reaction. It is an extremely weak acid, being liberated from most of its salts, for example,

KCN, by so weak an acid as carbonic. For this reason potassium cyanide always has the odor of the free acid. The free acid produces no precipitate with a mixture of a ferrous and ferric salt. On adding now caustic alkali, a dirty precipitate is formed, which goes into solution with excess of hydrochloric acid and forms immediately or after a few moments a precipitate of Prussian blue. Most of its salts, on being treated with diluted mineral or many organic acids, yield hydrocyanic acid, and are decomposed by strong nitric acid, with the evolution of nitrogen and other gases; silver cyanide dissolves in boiling nitric acid, the solution containing silver nitrate. A solution of an alkali cyanide mixed with a solution of picric acid and heated to about 60° C. (140° F.) acquires a deep-red color, from the production of a salt of *isopurpuric* or *picrocyanic acid*, $C_8H_5N_5O_6$ (Hlasiwetz, 1859).

Hydrocyanic acid is soluble in water, alcohol, and ether in all proportions. The official acid contains 2 per cent. of anhydrous acid; the aqueous solution of this strength has the specific gravity 0.997 (Br.). It is a colorless liquid, having a characteristic odor resembling that of oil of bitter almonds, and yields, when neutralized, the reactions characteristic of cyanides. Minute quantities of hydrocyanic acid may be detected by Schönbein's (see Guaiacum) or by Liebig's test (1847); the latter is applied by adding a little ammonium sulphide, a drop of dilute alkali, evaporating at a moderate heat to dryness, and adding to the residue, dissolved in water and slightly acidulated with hydrochloric acid, a drop of diluted ferric chloride, when the blood-red color of ferric sulphocyanate will appear.

Under various circumstances hydrocyanic acid is decomposed on keeping, evolving ammonium formate, cyanic acid, and carbon dioxide, and depositing a brown substance containing paracyanogen, C_3N_3 or C_6N_6. The causes of these changes have not been fully explained: it is, however, well known that the presence of alkalies and exposure to the light favor decomposition; and since, by heating hydrocyanic acid in the presence of free mineral acids, ammonium formate is apt to be produced, it will be seen that even recently prepared dilute hydrocyanic acid may be prone to change, and that, if altered, the decomposition cannot be arrested by distillation except after the previous addition of sufficient sulphuric acid. The addition of a minute quantity of hydrochloric acid, and of alcohol in place of a portion of the water, to the recently prepared acid, appears to retard that change, but does not altogether prevent it. The stronger the hydrocyanic acid is, the more liable it is to decomposition. The acid known as Scheele's acid, which contains 5 per cent. of HCN, is therefore not adapted for medicinal use.

Another difficulty in preserving the strength of hydrocyanic acid must be attributed to its volatility and the loss suffered by the medicinal acid on the frequent opening of the vial containing it. J. Williams states that an addition of 20 per cent. of glycerin will preserve acid up to the strength of about 5 per cent.; and J. U. Lloyd (1878) observed that alcoholic hydrocyanic acid could be kept in partially filled bottles unaltered and without material loss of acid for three years. Careful observations made by large manufacturers have thus far failed to suggest a desirable remedy for the well-known instability of hydrocyanic acid. The use of diluted alcohol as prescribed by the U. S. Pharmacopœia of 1880 gave no better results than the present method. Weaker solutions of hydrocyanic acid are known to keep better, but even these are not stable. The U. S. and Br. directions to keep the acid in a cool dark place should always be observed.

Tests.—Diluted hydrocyanic acid is completely volatilized by heat, and 10 Cc., when evaporated to dryness, should not leave a weighable residue. If 5 Gm. of diluted hydrocyanic acid be diluted with distilled water to measure 50 Cc., then 26.9 Cc. of this solution, after addition of 5 Cc. of ammonia-water and 3 drops of potassium iodide test-solution, should require for the production of a slight permanent precipitate the addition of not less than 10 Cc. of tenth-normal silver nitrate solution (U. S.). The Br. P. demands that each Gm. of the dilute acid made alkaline by the addition of sodium hydroxide solution shall require 3.7 Cc. of tenth-normal silver nitrate solution before a permanent precipitate appears.

The two last-named tests are practically identical. This process is known as Liebig's method, depending upon the formation of a double salt (alkali silver cyanide), which is not decomposed by an excess of alkali. The permanent turbidity occurs when all the hydrocyanic acid present is in combination as the double cyanide, and the further addition of silver nitrate solution then causes decomposition, insoluble silver cyanide sep-

arating. In the U. S. P. test the potassium iodide is added as an indicator, and will show the yellow color of silver iodide formed by interaction of silver cyanide and potassium iodide.

Impurities.—On adding a few drops of a solution of corrosive sublimate, and heating to boiling, a reduction of the mercuric salt to calomel or to mercury will indicate the presence of formic acid. Sulphuric acid is recognized by the white precipitate produced on the addition of barium chloride. Hydrochloric and phosphoric acids are detected by adding solution of borax, evaporating to dryness, and dissolving the residue in diluted nitric acid; a white precipitate with silver nitrate will indicate the former, and a yellow precipitate with ammonium molybdate the latter, impurity.

Action and Uses.—Hydrocyanic acid is probably the most rapidly acting drug we possess. In overdose it is a depressing protoplasmic poison, which is very rapidly absorbed and eliminated. Some of the drug is destroyed in the body, and a part of it may be found in the urine. Small doses stimulate respiration and the nervous system, but slow the circulation by stimulation of the vagi and depression of the heart muscle. Lethal amounts paralyze the respiratory center and the heart muscle, death, as a rule, being due to failure of respiration with almost simultaneous cessation of the action of the heart. Death may, however, result from syncope. Local applications of dilute solutions act as sedatives to the peripheral sensory nerves.

Hydrocyanic acid may be used with benefit in gastralgia, enteralgia, and in vomiting. It has been employed as a palliative in the cough of pulmonary tuberculosis. The drug has been recommended in whooping-cough, asthma, angina pectoris, and in the pain of gastric ulcer and gastric cancer. Its topical use often relieves the itching of many forms of skin disease.

When given in full medicinal doses the drug produces dizziness, roaring in the ears, staggering, headache, and salivation. The patient may experience a sense of tightness of the chest, laryngeal irritation, and irregular cardiac action. Muscular relaxation and mental hebetude may sometimes occur. Very large doses produce immediate death. As soon as the drug is ingested the patient utters a cry, falls to the floor, and immediately expires. In other cases where the dose is not so large the symptoms may be divided into three stages: The first is characterized by difficulty in breathing, a very slow heart action, and disturbance of the central nervous system. This occupies a very brief period, and immediately is followed by wild outcries, vomiting, convulsions of a clonic character (during which the tongue is bitten, causing the lips to become covered with a bloody froth), dilatation of the pupils, unconsciousness, involuntary urination, defecation, and ejaculation of semen. In the third stage death is preceded by asphyxia, paralysis, and collapse. After death the eyes are bulging and staring and the pupils widely dilated; the teeth are clinched and covered with bloody froth, and the face is cyanosed. Unless death has occurred instantly, the blood will be found dark and venous looking. As a rule the patient dies before treatment can be instituted. Applications of cold to the chest and spine, the internal administration of chlorine water and aromatic spirit of ammonia, with inhalations of ammonia gas, have been employed with some success. Atropine has been recommended, but probably is not sufficiently rapid in its action to be of benefit. The application of faradic electricity is also said to be of service.

Dilute hydrocyanic acid is given in the dose of from 2 to 3 minims (0.10–0.20 Cc.), repeated at frequent intervals. It is usually given with other remedies, and should be dispensed in a bottle which excludes the light. A lotion made by adding from 30 minims to a fluidrachm (2–4 Cc.) to 1 fluidounce (30 Cc.) of water, may be applied to the unbroken skin to control the itching and other distressing local symptoms of jaundice and urticaria.

ACIDUM HYPOPHOSPHOROSUM, *U. S.*—Hypophosphorous Acid.

Acide hypophosphoreux, Fr.; *Unterphosphorigesäure*, G.

Formula, HPH_2O_2 or $PO.H_2(OH)$. Molecular weight, 65.53.

A liquid composed of 30 per cent. by weight of absolute hypophosphorous acid and 70 per cent. of water. It should be kept in glass-stoppered bottles.—U. S.

Hypophosphorous acid was discovered by Dulong in 1816, and more fully investigated by H. Rose in 1826.

Preparation.—The U. S. P. does not give a process for manufacturing hypophosphorous acid. It may be prepared by decomposing potassium hypophosphite in solution by means of tartaric acid, and adding alcohol to the mixture to facilitate separation of the newly formed acid potassium tartrate, 208 parts of the hypophosphite requiring 300 parts of the acid. Another good plan is to decompose calcium hypophosphite in boiling solution by means of oxalic acid.

To prepare the official 30 per cent. acid, 138 Gm. of calcium hypophosphite are dissolved in 900 Cc. of boiling water, and to the solution is added a solution of 103 Gm. of pure oxalic acid in 400 Cc. of boiling water. The mixture is boiled for half an hour and, after cooling, filtered through cotton, and the precipitated calcium oxalate washed with cold water until it is free from all adhering acid. The filtrate is finally evaporated to 358 Gm. The reaction occurring is shown by the following equation: $Ca(PH_2O_2)_2 + H_2C_2O_4 = 2HPH_2O_2 + CaC_2O_4$.

Properties.—Hypophosphorous acid is a colorless liquid, without odor, and having an acid taste. It has a specific gravity of about 1.130 at 25° C. (77° F.), and is miscible with water in all proportions. Even when largely diluted with water, it has an acid reaction upon blue litmus-paper. When heated in a porcelain dish, water evaporates and the acid becomes more concentrated. On further heating, between 130° and 140° C. (266° and 284° F.), it decomposes, forming hydrogen phosphide, which ignites, and phosphorous acid: the latter, between 160° and 170° C. (320° and 338° F.), decomposes into hydrogen phosphide and phosphoric acid; the pasty residue finally reddens, ignites, and the last portions of unoxidized phosphorus burn out at a higher temperature. The addition of silver nitrate test-solution to hypophosphorous acid, diluted with an equal volume of water, produces a black precipitate of metallic silver; the addition of mercuric chloride test-solution, a white precipitate of mercurous chloride. When the acid is gently heated with copper sulphate test-solution, a yellow precipitate of copper hydride forms, which rapidly assumes a reddish-brown color.—U. S.

Hypophosphorous acid is a strong reducing agent, and as such is used to protect otherwise unstable solutions like those of ferrous iodide, hydriodic acid, etc.

Tests.—Neither platinic chloride test-solution nor sodium cobaltic nitrite test-solution should produce more than a slight yellow turbidity in hypophosphorous acid when diluted with water (limit of potassium). If some of the acid be neutralized with ammonia-water, a clear liquid should result, and a portion of this liquid should not become turbid upon the addition of potassium sulphate test-solution (absence of barium); nor should more than a slight turbidity be produced in another portion by barium chloride test-solution (limit of sulphuric, oxalic, and tartaric acids). 10 Cc. of the acid, warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of fresh hydrogen sulphide test-solution after standing stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). If 2 Cc. of hypophosphorous acid be measured into a beaker containing 3 Cc. of nitric acid, which has been previously diluted with about 10 Cc. of water, and the whole evaporated to dryness on a bath of boiling water, the residue should not respond to the modified Gutzeit's test for arsenic (see under Arseni Trioxidum). If 10 Gm. of hypophosphorous acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require not less than 30 Cc. of normal potassium hydroxide solution for neutralization, methyl orange being used as indicator, each Cc. corresponding to 1 per cent. of absolute hypophosphorous acid.—U. S.

Action and Uses.—This acid is used for making the Acidum Hypophosphorosum Dilutum.

Acidum Hypophosphorosum Dilutum, U. S.—*Diluted Hypophosphorous Acid,* E.; *Acide hypophosphoreux dilué,* Fr.; *Verdünnte Unterphosphorigesäure,* G.—Mix hypophosphorous acid, 200 Gm., with distilled water, 400 Gm.—U. S. Diluted hypophosphorous acid contains 10 per cent. of the absolute acid, and has a specific gravity of about 1.042 at 25° C. (77° F.). It corresponds in chemical properties with hypophosphorous acid, and should conform to the same reactions and tests. If 10 Gm. of diluted hypophosphorous acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require not less than 10 Cc. of normal potassium hydroxide solution for neutralization, phenolphthalein being used as indicator, each Cc. corresponding to 1 per cent. of absolute hypophosphorous acid.

Action and Uses.—Dilute hypophosphorous acid is rarely employed except in the form of its salts, the hypophosphites (see CALCII HYPOPHOSPHIS). It was at one time used as a tonic to the nervous system. The dose is from 10 to 30 minims (0.60–2 Cc.), given well diluted with water.

ACIDUM LACTICUM, *U. S., Br., P. G.*—Lactic Acid.

Isolactic, Ethyledene-lactic, or Oxypropionic acid, E.; *Acide lactique*, Fr.; *Milchsäure*, G.; *Acido lactico*, Sp.

Formula, $HC_3H_5O_3$ or $CH_3.CHOH.COOH$. Molecular weight, 89.37.

Official lactic acid contains 75 per cent. of the absolute acid.

Origin.—Lactic acid was discovered by Scheele (1780) in sour milk, in which it results from the spontaneous fermentation of the sugar of milk under the influence of the casein. This transformation of the former into the latter is called the *lactic fermentation*. A similar change is produced in dextrin, glucose, cane-sugar, etc., by the action of casein and other protein compounds: lactic acid is therefore met with in many vegetable products which have turned sour. T. and H. Smith's *thebolactic acid* of opium is identical with the lactic acid of milk; but the sarcolactic acid of meat-juice, discovered by Berzelius (1807), and recognized by Liebig as differing in several respects from the lactic acid of milk, consists of two acids, one of which, known as *paralactic acid*, has the composition given above, but is dextrogyre, and the solutions of its salts have a levogyre action. The second lactic acid of flesh is like that of milk, optically inactive, but is *ethylenelactic acid*, having the composition $CH_2OH.CH_2.COOH$, and its zinc salt is soluble in absolute alcohol. Strecker (1858) observed that by heating sarcolactic acid for some time at 130° or 140° C. (266° or 284° F.) the anhydride is produced, which, dissolved in boiling water, yields ordinary lactic acid. During lactic fermentation, alcohol, several acids, a peculiar gum, and mannite are formed in variable proportions, more particularly if the temperature be allowed to vary much from about 45° C. (113° F.).

Preparation.—Lactic acid may be obtained in several ways. If a mixture of sugar, water, fresh cheese, and chalk be set aside for several weeks in a sunny place, calcium lactate will crystallize out, which may then be decomposed by a calculated quantity of sulphuric acid, and the resulting solution of lactic acid concentrated by evaporation. Milk-sugar and inverted sugar may be used for fermentation, and zinc oxide may be substituted for the chalk. In the latter case zinc lactate will be obtained, from which the zinc is removed by hydrogen sulphide.

A more rapid method is that of Kiliani (1882), in which 500 Gm. of cane-sugar, dissolved in 200 Gm. of water, are converted into inverted sugar by boiling with 10 Cc. of sulphuric acid; 450 Cc. of a solution made of equal parts of caustic soda and water, are added gradually, and the mixture is heated to 60° or 70° C. (140°–158° F.) until it ceases to react for sugar with Fehling's Solution. The liquid is allowed to cool and neutralized with sulphuric acid, the sodium sulphate allowed to crystallize, and the remainder precipitated by addition of alcohol; one-half of the clear alcoholic liquid containing the lactic acid is heated, neutralized with zinc carbonate, mixed with the other half, and cooled, when zinc lactate will crystallize, from which the acid may be obtained in the usual way.

Recently (1899) a process has been patented in Germany for recovering the lactic acid produced in the manufacture of the so-called "sour-krout." This consists in neutralizing the liquors of the sour-krout factories with lime, filtering the solution, evaporating, and crystallizing. The crystals of calcium lactate are freed from sodium chloride by washing with water, recrystallized if necessary and decomposed by means of sulphuric acid.

Two commercial varieties of lactic acid are met with, designated respectively as concentrated and dilute lactic acid; as neither specific gravity nor percentage strength is indicated, these terms are meaningless, and sure to lead to confusion.

Absolute lactic acid cannot be prepared under ordinary conditions of evaporation, water being split off and insoluble lactic anhydride, $C_6H_8O_4$, resulting. If repeatedly rectified under reduced pressure, 12 millimeters, the pure acid is obtained in the form of a crystalline mass melting at 18° C. (64.4° F.).

Properties.—Official lactic acid is a syrupy colorless liquid, having no odor, a very sour taste, and the specific gravity 1.213 at 15° C. (59° F.), 1.206 at 25° C.

(77° F.) (U. S.); it absorbs moisture when exposed to damp air; the pure acid is colorless, inodorous, and has the specific gravity, according to Mendelejeff, 1.2485 at 15° C. (59° F.). It is miscible in all proportions with water, alcohol, and ether, but is insoluble in chloroform, carbon disulphide, and benzin. On warming the acid with potassium permanganate the odor of aldehyde is given off. Lactic acid is not vaporized by a heat below 160° C. (320° F.). At a higher temperature it emits inflammable vapors and is finally dissipated; 5 Gm., after combination, should not leave more than 0.05 Gm. of fixed residue (U. S.). It coagulates milk and albumin, and displaces carbonic and acetic acids from their compounds, yielding salts which are soluble in water, and mostly also in alcohol. Lactic acid, on being oxidized by nitric acid, yields oxalic acid, and by treatment with chromic acid formic and acetic acids are produced. 90 grains of the official acid are neutralized by 75 grains of potassium bicarbonate, or 4.5 Gm. of the acid by 37.5 Cc. of volumetric solution of sodium hydroxide, indicating 75 per cent. of $HC_3H_5O_3$, phenolphthalein being used as indicator.

Tests.—Treated with a hot solution of potassium hydroxide, lactic acid is not materially colored; if it readily becomes brown, extractive matters are present. Dissolved in strong alcohol, gum and some mineral salts are left behind. Glycerin, glucose, mannite, tartaric acid, and most salts remain undissolved by ether. Acetic and butyric acids are recognized by their odor, which becomes more apparent on warming. For detecting other organic and mineral acids, their special tests may be applied. In the diluted acid calcium salts are indicated by ammonium oxalate; lead, by hydrogen sulphide; zinc, after neutralization with ammonia, by ammonium sulphide; sulphuric acid, by barium chloride; sarcolactic acid, by copper sulphate; hydrochloric acid, by silver nitrate; and oxalic acid, by calcium chloride, after previously diluting the acid with 20 times its quantity of water and neutralizing with ammonia. On saturating the acid with zinc carbonate, drying at 100° C. (212° F.), and treating with absolute alcohol, zinc sarcolactate will be dissolved: also glycerin and mannite, if present, imparting a sweet taste to the alcohol.

Adding 1 Cc. of lactic acid, drop by drop, to 2 Cc. of ether, no turbidity, either transient or permanent, should be observed (P. G.); this is intended to prove the absence of glycerin, sugar, mannite, etc. The absence of sugars is determined also by the failure of the acid to produce red cuprous oxide on being added to hot Fehling's Solution. Solution of copper sulphate should have no effect upon a 10 per cent. solution of lactic acid (absence of sarcolactic acid). The limits of allowable impurities are determined as follows: "10 Cc. of a 1 per cent. aqueous solution of the acid should not be rendered opalescent by the addition of 1 Cc. of decinormal silver nitrate solution (limit of chloride). On mixing equal volumes of lactic and colorless sulphuric acid in a clean test-tube and keeping the temperature at or below 15° C. (59° F.), no dark-colored zone should develop at the line of contact upon standing for 15 minutes (absence of more than traces of organic impurities). If 5 Gm. of lactic acid be diluted with water to measure 50 Cc., then 44.7 Cc. of this solution should require for complete neutralization not less than 37.5 Cc. of normal potassium hydroxide solution, phenolphthalein being used as indicator, each Cc. corresponding to 2 per cent. of absolute lactic acid."—U. S.

Action and Uses.—It is stated that lactic acid is a normal constituent of the gastric juice, and in combination with pepsin it has been proposed in the treatment of atonic dyspepsia. The drug has been employed as a curative application in laryngeal tuberculosis and in infantile diarrhœas. Uric acid diathesis, phosphaturia, and oxaluria depending upon improper assimilation are frequently benefited by its use. It has also been recommended in chronic cystitis due to ammoniacal decomposition of urine. Lactic acid has been employed with varying success in the treatment of diabetes, but the remedy is now rarely prescribed. As a hypnotic it is valueless, and is no longer used. The drug dissolves false membrane, and a solution of 1 part of the acid in 6 parts of water may be employed with advantage in the local treatment of diphtheria and croup. Local applications of the pure acid are successful in arresting the growth of venereal warts, and are recommended in the treatment of tuberculous ulcers, lupus, and epithelioma.

Lactic acid may be given in the dose of 15 to 30 minims (1–2 Cc.) 3 times daily. It is usually prescribed before or during the meal, and should be largely diluted and sweetened to suit the taste. After its administration the mouth should be rinsed with a solution of sodium bicarbonate.

ACIDUM NITRICUM, *U. S., Br., P. G.*—Nitric Acid.

Acidum nitri s. azoticum, Spiritus nitri acidus.—Acide azotique s. nitrique, Fr.; *Salpetersäure,* G.; *Acido nitrico,* It., Sp.

Formula, $HNO_3 = NO_2.OH$. Molecular weight, 62.57.

The official nitric acid of the different pharmacopœias varies in strength; thus while the U. S. requires 68 per cent. of absolute acid, the Br. demands 70 per cent. and the P. G. only 25 per cent. Specific gravity about 1.403 at 25° C. (77° F.) and boiling-point 120.5° C. (248.9° F.).—U. S.

Origin.—Nitric acid occurs occasionally in the free state, but more usually as the ammonium salt, in very small quantity in the air, rain water and spring water. Its presence in the air is due to electric discharges, by which nitrogen and oxygen combine. Nitrates of sodium, potassium, ammonium, magnesium, and calcium are distributed very widely as a normal constituent of the humus of soil. Their presence is due to the oxidation to nitric acid of ammonia and other nitrogen products which result from the putrefaction of vegetable and animal matter. This oxidation is facilitated by bacteria, which act as a nitrifying ferment. The nitrates thus formed accumulate in beds in regions where water is scarce, for example, the large sodium nitrate beds in rainless districts of Peru (province of Tarapaca and the desert of Atacama), and Chilian Bolivia. Smaller beds are formed in Spain, the trans-Caspian district, and India.

A process for preparing this acid was made public first by Geber in the eighth century, and its composition was determined by Cavendish (1785) and Davy (1816). For medicinal and technical purposes nitric acid is made by decomposing sodium or potassium nitrate by sulphuric acid.

Preparation.—1. Acidum Nitricum.—It is prepared on the large scale in apparatus constructed similar to that used in the manufacture of hydrochloric acid. Formerly all nitric acid, whether on the large or small scale, was prepared from the more expensive but easily purified potassium nitrate, but now, since processes have been devised for obtaining the cheaper sodium nitrate or Chili saltpeter pure, the latter is used almost exclusively in the manufacture of the acid. The heat required is less than in the case of potassium nitrate, and the following reaction takes place: $H_2SO_4 + 2NaNO_3 = 2HNO_3 + Na_2SO_4$. When potassium nitrate is used, such proportions of it and sulphuric acid are taken as correspond to this reaction: $KNO_3 + H_2SO_4 = KHSO_4 + HNO_3$. The heat required to carry out the complete exchange between the nitrate and acid—thus, $2KNO_3 + H_2SO_4 = K_2SO_4 + 2HNO_3$—is so high as to decompose some of the nitric acid into water, oxygen, and red oxides of nitrogen. The red fumes dissolve in the nitric acid which condenses in the receiver, thus giving it a reddish-brown color. Hence the process is carried out according to the first reaction unless it is desired to make colored acid, which is known as *red fuming nitric acid.*

Nitric acid which is colored from the presence of oxides of nitrogen may be decolorized by applying a moderate heat or by passing a current of dry carbon dioxide through it.

Impure acid containing chlorine or iodine, derived from impure niter or Chili saltpeter, or sulphuric acid, may be purified by distillation over lead nitrate, and discarding the first distillate until silver nitrate gives no precipitate.

Approximately 100 per cent. acid can be obtained by mixing very concentrated acid with absolute sulphuric acid and carefully distilling at a greatly reduced pressure.

2. Acidum Nitricum Fumans, P. G.; *Acidum nitroso-nitricum, Spiritus nitri fumans.—Fuming nitric acid, Nitroso-nitric acid,* E.; *Acide azotique fumante,* Fr.; *Rauchende Salpetersäure,* G.—A clear reddish-brown acid giving off suffocating yellowish-red fumes; strength, 86 per cent. or more of absolute nitric acid; specific gravity, 1.486–1.50 at 15° C. (59° F.).

3. Acidum Nitricum Crudum, P. G.; *Crude nitric acid,* E.; *Rohe Salpetersäure,* G.—A clear colorless or faintly yellow liquid, when heated volatile without residue, and containing 61 per cent. of absolute HNO_3. Its specific gravity is 1.38–1.40. at 15° C. (59° F.).

Properties.—1. Nitric Anhydride, Nitrogen Pentoxide.—This was discovered by St. Clair Deville (1849) in decomposing pure crystallized silver nitrate by absolutely dry chlorine gas. It forms colorless shining prisms, which readily decompose into nitrogen tetroxide and oxygen, fuse at about 30° C. (86° F.) into a liquid boiling near 50° C. (122° F.), and deliquesce rapidly when in contact with moist air. Its composition is N_2O_5, molecular weight, 107.82; combining with 1 molecule of water, H_2O, it forms 2 molecules of nitric acid, $2HNO_3$.

2. Crude Nitric Acid.—As met with in commerce, it is either colorless or of a pale yellowish color, and contains the impurities mentioned above, together with a little iron. It is often called *aqua fortis;* the weaker kind is of about 1.21 specific gravity, being known as single aqua fortis, and the stronger, of specific gravity 1.37, as double aqua fortis. Crude nitric acid is extensively used in many chemical processes.

3. Pure Nitric Acid.—It is a colorless fuming liquid, wholly volatilized by heat. It colors animal tissue yellow (xanthoproteic reaction) and causes deep and slowly healing sores. It decolorizes a solution of indigo when heated with it, and has an intense acid reaction even in very dilute solution. The strength is determined by diluting the acid with water and neutralizing with normal sodium hydroxide solution, of which 3.13 Gm. of the acid require 34 Cc. (U. S.), or 1 Gm. requires 11.1 Cc. (Br.), indicating respectively 68 and 70 per cent. of HNO_3, or 58.29 and 60 per cent. of N_2O_5, each Cc. of alkali representing 0.0626 Gm. of HNO_3. Nitric acid, P. G., is much weaker, having the specific gravity 1.153 and containing 25 per cent. of HNO_3, as stated above.

Nitric acid is a powerful oxidizing agent, converting most metals into oxides or nitrates, and decomposing most organic compounds. Orange-red vapors are given off during the action. It decomposes in direct or diffused sunlight into brown oxides of nitrogen, which color the acid reddish. All nitrates are soluble in water; a few so-called subnitrates are insoluble in water—*e. g.*, bismuth subnitrate. The concentrated acid, corresponding in composition to the formula HNO_3, has at 0° C. (32° F.) the specific gravity 1.559. When exposed to the light or heated to near its boiling-point, 86° C. (186.8° F.), it is decomposed partly into water and nitrogen tetroxide, so that its boiling-point is not constant. Nor is the boiling-point of weaker acids constant. Those below and those above the specific gravity 1.42 boil at a constantly rising temperature, until the acid in the retort has been raised or lowered in strength to correspond to the formula $2HNO_3.3H_2O$, when its boiling-point will be stationary at 121° C. (249.8° F.), and it will have at 15.5° C. (60° F.) the specific gravity 1.42 (Graham). This strength of nitric acid has been adopted as the official standard in the British Pharmacopœia. According to Roscoe, nitric acid containing between 65 and 70 per cent. of hydrogen nitrate yields, after continued boiling, a liquid the boiling-point of which is 120.5° C. (248.9° F.) at a barometer pressure of 735 Mm., and the specific gravity of which is 1.414 at 15.5° C. (60° F.). This is the acid recognized in the United States Pharmacopœia, and contains 68 per cent. of hydrogen nitrate, while Graham's acid should contain 69.96 per cent. The existence of a definite hydrate having a constant boiling-point appears, therefore, somewhat doubtful.

The following table, incorporated in the Pharmacopœia, shows the specific gravity of nitric acid as compared with water at 15° and 25° C. (59° and 77° F.), and also the quantity of normal KOH solution required to neutralize 1 Cc. of acid of different strengths:

Per cent. nitric acid.	Specific gravity— 25° C. / 25° C.	Specific gravity— 15° C. / 15° C.	Correction of specific gravity for 1° C.[1]	Fractional per cent.[2]	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc normal KOH.

The density of pure nitric acid varies with its strength. In taking its specific gravity the absence of notable quantities of nitrogen tetroxide should be ascertained, since they increase the density.

4. Fuming Nitric Acid has a brown-red color, and when in contact with the air emits vapors of the same color, which have a suffocating odor. It requires to be kept in a cool place, and caution should be exercised in removing the stopper, lest a portion of the liquid should be ejected violently with the escaping vapors. The German Pharmacopœia requires for this preparation a specific gravity of from 1.486 to 1.50 The so-called *nitrous acid* of commerce is a similar but weaker article, consisting of nitric acid which is colored red by variable quantities of nitrogen tetroxide.

Impurities.—Such as are likely to be present have been mentioned above. Mineral impurities are left as a fixed residue on evaporation, and may then be recognized by appropriate tests.

Tests.—5 Cc. of diluted nitric acid (1 in 10) should not respond to the modified Gutzeit's test for arsenic (see under Arseni Trioxidum). Other portions of this dilution should not yield a precipitate with barium chloride test-solution (absence of sulphuric acid), or with silver nitrate test-solution (absence of hydrochloric acid). 10 Cc. of the diluted acid (1 in 20) warmed to 50° C. (122° F.) should not be colored or rendered turbid by an equal volume of fresh hydrogen sulphide test-solution after standing corked at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). If the diluted acid (1 in 3) be shaken with a few drops of chloroform, the latter should remain colorless (absence of iodine or bromine) even after the introduction of a small piece of zinc (absence of iodic or bromic acid). The latter acids would be reduced by zinc to hydriodic or hydrobromic acid, which with nitric acid would decompose, giving free iodine or bromine.

Acidum Nitricum Dilutum, U. S., Br.—*Diluted nitric acid*, E.; *Acide azotique dilué*, Fr.; *Verdünnte Salpetersäure*, G.

Preparation.—Diluted nitric acid is prepared by mixing 10 Gm. of nitric acid with 58 Gm. of distilled water (U. S.). Or 1 part of nitric acid may be mixed with 5.8 parts of water, all by weight. The British Pharmacopœia directs that to 274.3 Gm. (or 2400 grains) of nitric acid shall be added sufficient distilled water to bring the volume of the mixture up to 1000 Cc. (or 1 Imperial pint) at 15.5° C. (60° F.).

Properties.—Diluted nitric acid is a colorless odorless liquid of decided acid taste and reaction. It contains 10 per cent. of absolute nitric acid (U. S.) or 17.44 per cent. (Br.), and has the specific gravity 1.054 at 25° C. (77° F.) (U. S.) or 1.101 (Br.). 6.26 Gm. of the liquid require 10 Cc. (U. S.) or 16.90 Cc. (Br.) of normal sodium hydroxide solution for neutralization, using phenolphthalein as indicator. In its other properties and tests it conforms to those given for nitric acid.

Action and Uses.—Concentrated nitric acid acts as a powerful escharotic upon the tissues of the body and causes them to assume a lemon-yellow color. Local applications of the diluted acid are irritating and astringent.

In small doses the drug stimulates the secretory glands of the stomach and intestines.

Poisonous doses of the concentrated acid cause violent gastro-enteritis, with burning pain in the mouth and œsophagus; hæmaturia occasionally occurs and bloody stools are common. The pain and inflammation are very violent; the patient passes into collapse

and frequently dies. Should recovery from the acute symptoms occur, death may result later from stricture of the œsophagus or destruction of the peptic tubules. Mild alkaline solutions or whitewash from the surface of walls are the best antidotes. The administration of bland oils and opium, to relieve irritation, and the maintenance of bodily heat are measures which should be instituted at the earliest opportunity.

Nitric acid may be employed with success in the treatment of gastric and intestinal indigestion, in enteric diarrhœa, and in infantile diarrhœa when the stools are of a green color. It has been employed with benefit in oxaluria and phosphaturia. The drug has also been recommended in diabetes, syphilis, syphilitic jaundice, chronic impetigo, and intermittent fever, but at present is rarely employed in these conditions.

Lotions of nitric acid in the proportion of ½ to 1 drachm (2–4 Gm.) to a pint (480 Cc.) of water have been employed to arrest hemorrhage from bleeding hemorrhoids, and the pure acid when touched to one or two points of a hemorrhoid sometimes produces a cure. It may be employed locally as a caustic for the bites of rabid animals, poisonous serpents, and insects, and in its dilute form is an excellent application for syphilitic and other sores of the mouth.

Nitric acid is often used as a test for albumin in the urine. If the acid be placed first in a tube and the suspected urine be allowed to flow down gently and overlay it, a zone of coagulated albumin will appear at the line of contact if albumin is present.

The dose of nitric acid is from 5 to 10 minims (0.3–0.6 Cc.) 3 times daily, largely diluted, and taken through a glass tube.

ACIDUM NITROHYDROCHLORICUM, *U. S.*—Nitrohydrochloric Acid.

Acidum chloro-nitrosum, Acidum nitromuriaticum, Aqua regia, Aqua regis.—Nitromuriatic acid, E.; *Acide chloro-azotique s. chloro-nitreux, Eau régale*, Fr.; *Salpetersalzsäure, Königswasser*, G.

Preparation.—Take of nitric acid, 180 Cc.; hydrochloric acid, 820 Cc. Mix the acids in a capacious glass vessel, and when effervescence has ceased pour the product into glass-stoppered bottles, which should not be more than half-filled, and keep them in a cool dark place.—*U. S.* (If 4½ fluidrachms of nitric acid and 20½ fluidrachms of hydrochloric acid be mixed, the official proportions will remain undisturbed.) The French Codex directs 80 parts of nitric acid, specific gravity 1.39, 20 parts of water, and 300 parts of hydrochloric acid, specific gravity 1.17.

This preparation should never be made extemporaneously, as time must be allowed for complete reaction, which is ascertained by cessation of effervescence; moreover, the vessel containing the acids should be kept in a cool place in the open air, as the fumes arising from the mixture are extremely annoying. As soon as reaction has ceased, the liquid should be poured into bottles as directed, and kept in a cool dark place, so that the chlorine and nitrosyl chloride may remain as such. At a low temperature this mixture may be kept without evolution of gas, but at ordinary or a somewhat elevated temperature a variable mixture of gas is given off; hence the necessity of not dispensing this preparation until after effervescence has ceased, and of keeping it in vials not quite filled.

On mixing nitric with hydrochloric acid a decomposition takes place, resulting in the liberation of chlorine and the formation of water and a chlorinated oxide of nitrogen, NOCl. This preparation has received the name of *aqua regia* from its property of dissolving gold, which is due to the presence of free chlorine; for the same reason are dissolved platinum, calomel, and all other metals and compounds which yield soluble chlorides. Its activity therefore depends upon the amount of free chlorine contained in it. The change taking place on mixing the acids is expressed thus, $HNO_3 + 3HCl = Cl_2 + NOCl + 2H_2O$. The *nitrosyl chloride*, NOCl, is a yellowish gas, which becomes a red liquid at −5° C. (23° F.).

Properties.—Nitrohydrochloric acid is a liquid having a deep golden-yellow color and the odor of chlorine. It readily dissolves gold-leaf, liberates iodine and bromine from their salts, and is volatilized wholly by heat. It should be kept in a cool and dark place, and dispensed in dark- or yellow-colored bottles; and the patient should be cautioned against exposing the vial to light and heat, so as to avoid accidents. It should not be kept on hand for a long time.

Action and Uses.—This acid, like those that compose it, is an intense irritant and caustic when in concentrated form. Taken in full dose, it may irritate the stomach, and

it attacks the enamel of the teeth in its passage through the mouth unless taken through a tube. When placed in the warm water of a bath, it is absorbed by the skin and causes the urine to be acid. Taken internally, its effect on the bowels is laxative and it is stimulant to the flow of bile.

The dilute acid soon loses its peculiar properties, and the freshly prepared strong acid, which is of an orange color, should be used.

Overdoses of the strong acid destroy the mucous membranes of the mouth, pharynx, and œsophagus, causing severe, burning pain, and very violent gastro-enteritis. The inflammation frequently extends to the other abdominal viscera. Perforation of the stomach or intestines, causing peritonitis, may occur. Vomiting and bloody stools are not uncommon. Early collapse followed by death frequently ensues. Patients recovering from the acute symptoms usually die at a later period from stricture of the œsophagus or intestines, or from destruction of the peptic tubules. The poisoning is treated best by the administration of mild alkalies, such as lime water, magnesia, chalk, or whitewash from walls. Opium and bland oils may be employed to relieve pain and irritation. External heat to maintain bodily temperature and stimulants when indicated, should be resorted to.

Nitrohydrochloric acid has been employed in hepatic torpor, chronic hepatitis, hepatic cirrhosis, and in chronic dysentery. It may also be used in gastric and intestinal indigestion, and has been recommended in phosphaturia, oxaluria, and the various conditions depending upon the uric acid diathesis. A certain amount of success has been derived from its administration in full doses in the treatment of hypochondriasis and melancholia. Baths containing 5 per cent. of the acid may be employed as adjuncts in the treatment of the above conditions.

Concentrated nitrohydrochloric acid may be applied locally to venereal sores and phagedenic ulcers, but great care should be taken to prevent it from destroying healthy tissue as well.

The dose of the stronger acid is 3 to 6 minims (0.20–0.40 Cc.), well diluted, and of the diluted form 15 to 30 minims (1–2 Cc.), largely diluted and taken through a glass tube. Because of its destructive action upon the teeth, the mouth should be washed thoroughly with a solution of sodium bicarbonate immediately after its ingestion.

ACIDUM NITROHYDROCHLORICUM DILUTUM, *U. S.*, *Br.*—Diluted Nitrohydrochloric Acid.

Acidum nitromuriaticum dilutum.—Diluted nitromuriatic acid, E.; *Acide chlorazotique dilué*, Fr.; *Verdünnte Salpetersalzsäure*, G.

Preparation.—Take of nitric acid, 40 Cc.; hydrochloric acid, 180 Cc.; distilled water, 780 Cc. Mix the acids in a capacious open glass vessel, and when effervescence has ceased add the distilled water. Keep the product in dark amber-colored glass-stoppered bottles in a cool place.—U. S. (By mixing 2 fluidrachms of nitric acid with 9 fluidrachms of hydrochloric acid, and finally adding 39 fluidrachms of distilled water, the official strength will be preserved.)

It is imperative that the reaction between the strong acids be completed before the water is added. When the mixture is diluted with water, NOCl is decomposed thus, $NOCl + H_2O = HCl + HNO_2$, giving hydrochloric and nitrous acids. It is evident therefore that the diluted nitrohydrochloric acid does not contain the same products as the original undiluted mixture. This subject has been investigated by Tilden, and also by Redwood, of England (*Pharm. Jour. and Trans.*, x. 508), who found that diluted nitrohydrochloric acid contains hydrochloric, nitric, and a little nitrous acids.

The British Pharmacopœia merely directs that 3 fluidounces of nitric acid and 4 fluidounces of hydrochloric acid be added to 25 fluidounces of distilled water, the mixture to be kept in a glass-stoppered bottle for 14 days before it is used. The dilute acid must have a specific gravity of 1.07, and 4 Gm. require for neutralization about 10 Cc. of normal solution of sodium hydroxide.

Properties.—Diluted nitrohydrochloric acid is a colorless liquid having a faint odor of chlorine when freshly made and a very acid taste. Like the strong acid, it is completely volatilized by heat and liberates iodine and bromine from their salts. It contains nearly one-fourth as much acid as the stronger preparation, but, as already explained, has an entirely different composition.

For uses and dose of the diluted acid, see the preceding article.

ACIDUM OLEICUM, *U. S., Br.*—Oleic Acid.

Acidum oleinicum, Acidum elainicum.—Elaic acid, E.; *Acide oléique,* Fr.; *Oelsäure, Oleinsäure, Elainsäure,* G.

Formula, $HC_{18}H_{33}O_2$ or $C_{17}H_{33}COOH$ or $CH_3(CH_2)_7CH.CH(CH_2)_7COOH$. Molecular weight, 280.14.

History and Occurrence.—The earliest references to oleic acid were made by Chevreul in 1823. It was prepared first in a pure state by Gottlieb in 1846. It occurs as a glyceryl ester, triolein, in greater or less amount in almost all fats. Especially rich are the non-drying fatty oils, such as almond oil, olive oil, etc.

Preparation.—Large quantities of crude oleic acid are obtained as a by-product in the manufacture of stearic acid for stearin candles. It contains variable amounts of stearic and palmitic acids, frequently also fatty acids with a lower number of carbon atoms. The two first mentioned impurities can be in large part removed by exposing the impure acid to a low temperature.

For the preparation of a pure oleic acid, the fatty acids of almond oil are converted into their lead salts by digesting with lead oxide in the presence of water. When dried, the oleate of lead can be separated from the other salts by solution in ether. From the ethereal solution the lead is precipitated as chloride with hydrochloric acid, and the filtered ethereal solution of oleic acid evaporated. This product can be purified further, if desired, by dissolving it in ammonia, precipitating the barium salt by the addition of barium chloride, repeated recrystallization from alcohol, and final liberation of the oleic acid with tartaric acid with exclusion of air.

Properties.—The official acid has a specific gravity of 0.900 at 15° C. (59° F.), about 0.895 at 25° C. (77° F.) (U. S.), and its solution in alcohol has a feebly acid reaction upon litmus-paper; it is prepared from a good quality of commercial acid (usually known as "Red Oil") by cooling the latter to 5° C. (41° F.), and separating the liquid portion from palmitic and other acids. When cooled to 4° C. (39.2° F.), oleic acid becomes semisolid, and on further cooling congeals to a whitish solid mass.—U. S.

Pure oleic acid is a colorless, inodorous, and tasteless oily liquid, of neutral reaction, having at 19° C. (66.2° F.) the density 0.898 (Chevreul), congealing to a white crystalline mass at 4° C. (39.2° F.), and crystallizing from alcohol in dazzling white needles melting at 14° C. (57.2° F.) (Gottlieb). The solid acid is but little affected by exposure to air, but in the liquid state it rapidly absorbs oxygen on exposure, becoming yellow and brown, and acquiring a rancid odor, lower congealing-point, and an acid reaction. The official oleic acid has a yellowish or brownish-yellow color, and a peculiar, lard-like odor and taste. When heated to a temperature of about 95° C. (203° F.), decomposition commences, and acrid vapors are produced; at a higher temperature it is completely dissipated (U. S.). It may be distilled *in vacuo* without decomposition, but if distilled in contact with air yields carbon dioxide, hydrocarbons, and an oily distillate containing *sebatic acid*, $C_{10}H_{18}O_4$. With melted potassium hydroxide it is decomposed into palmitic and acetic acids. It is a solvent for fats and fatty acids, is insoluble in water, and dissolves in all proportions of alcohol, ether, chloroform, benzin, and other hydrocarbons, volatile and fixed oils. It unites with bases, and when heated slowly decomposes the alkali and earthy carbonates, forming soaps. Many of the oleates are soluble in alcohol, several also in ether; the normal lead oleate is white, melts at 80° C. (176° F.), and dissolves in ether and benzin. Oleic acid left in contact with nitrous acid is converted into the isomeric *elaidic acid*, which crystallizes in pearly plates and melts at 44° C. (111.2° F.). When oxidized by nitric acid, succinic and several other acids are obtained.

Tests.—A solution of oleic acid in an equal volume of alcohol at ordinary temperature should be perfectly transparent and not separate a layer of fixed oil, and at 7.2° C. (45° F.) should not yield a crystalline deposit of stearic or palmitic acid. To show the absence of notable quantities of stearic and palmitic acids, the U. S. Pharmacopœia requires oleic acid to stand the following test: 1 Gm. of the acid is heated with 20 Cc. of alcohol, and after the addition of two drops of phenolphthalein solution sodium hydroxide solution (1 to 4) is dropped into the liquid until it has acquired a permanent red tint; acetic acid is then added to the liquid until the red color is just discharged, and the liquid filtered. 10 Cc. of the filtrate, mixed with 10 Cc. of ether, should not be rendered more than slightly turbid by 1 Cc. of lead acetate test-solution.

Commercial oleic acid is said to be adulterated frequently with linoleic acid, which admixture can be detected even to the extent of 1 per cent. by treating with potassium permanganate, whereby oleic acid is converted into azaleinic acid, soluble in ether, whereas linoleic acid yields sativic acid insoluble in ether (*Proc. Amer. Pharm. Assoc.*, 1890).

Action and Uses.—Oleic acid is employed in medicine only in combination. It is used in the preparation of oleates, which are considered by some more elegant preparations than ointments, as they do not deteriorate and are less irritating to the skin.

Derivative.—SULPHOLEIC ACID. $C_{17}H_{32}(SO_3H)COOH$.—When almond, castor, or olive oil is treated for 8 or 10 hours with 30 or 40 times its weight of concentrated sulphuric acid at a temperature not exceeding 50° C. (122° F.), the reaction being controlled by cooling with ice if necessary, decomposition results, sulpholeic acid and glyceryl-sulphuric acid being formed; the latter together with the diluted sulphuric acid is decanted and the residue washed with water. The crude acid is neutralized with alkali carbonates or hydroxides, to be subsequently decomposed with sulphuric acid and the purified sulpholeic acid extracted with benzin or ether, which yields the acid in anhydrous condition upon evaporation. If castor oil be used, the resulting acid is designated more specifically as sulphoricinoleic acid. Sulpholeic acid forms neutral salts with the alkalies, which are soap-like compounds readily soluble in water, and possess the property of taking up large quantities of substances otherwise immiscible with water. The alkali sulpholeates have at different times been placed on the market under such names as *oleite, solvine, polysolve*, etc.

ACIDUM OXALICUM.—Oxalic Acid.

Acide oxalique, Fr.; *Oxalsäure, Kleesäure, Sauerkleesäure*, G.

Formula, $H_2C_2O_4.2H_2O$ or $COOH.COOH + 2H_2O$. Molecular weight, 125.10.

Oxalic acid is officially recognized in the French and Italian Pharmacopœias.

History and Occurrence.—The acid potassium salt of oxalic acid was prepared as early as the middle of the seventeenth century by Angelus Sala from *Rumex acetosa*. It was examined later by Marggraf (1740), and by Savary (1773). The free acid was prepared first by Scheele (1776) by the oxidation of sugar; later (1784) he demonstrated the identity of this acid with that previously found as potassium salt in nature. Although free oxalic acid is of rare occurrence in the vegetable kingdom (*Boletus sulfureus, B. ignarius, Cicer arietinum*, etc.), its salts are distributed very widely. The potassium salt is found in various species of *Oxalis*, hence the name (the German for *Oxalis acetosella* is *Sauerklee*, hence *Sauerkleesäure* and *Kleesäure*); and of *Rumex* also in *Geranium acetosum, Spinacea oleracea, Phytolacca decandra, Rheum palmatum, Atropa Belladonna*, etc. The sodium salt occurs in most species of *Salsola* and *Salicornia*, the ammonium salt in guano. Especially common is the occurrence of calcium oxalate, either in solution or deposited as crystals in cells. In the animal kingdom also oxalic acid is found, especially as calcium salt, *e. g., as sediment in urine*, etc. It occurs in the form of ferrous oxalate in the mineral kingdom, as oxalite or humboldtite, etc.

Preparation.—(1) From sugar: 1 part of granulated sugar is heated with 8 parts of crude nitric acid, first gently, then to boiling. After the evolution of gases has ceased, the solution is evaporated to one-sixth of the original volume and allowed to cool. The crystals, when formed, are collected on a filter, washed with cold water and purified by recrystallization. Oxalic acid thus prepared can readily be obtained chemically pure.

(2) From cellulose: Sodium oxalate, obtained by heating sawdust with soda and potassa (60:40) lye (specific gravity 1.35) to 240°–250° C. (464°–482° F.) until dry, lixiviating and crystallizing the sodium salt, is precipitated as calcium oxalate, and the oxalic acid freed by means of sulphuric acid. The acid is purified by crystallization. By this process sawdust yields about half its weight of oxalic acid. Anhydrous oxalic acid can be obtained in crystals by dissolving oxalic acid, which has been deprived of its water of crystallization by heating to 100° C. (212° F.), in $2\frac{1}{2}$ parts of hot glacial acetic acid and allowing to cool. It melts at 186°–187° C. (366.8°–367.6° F.).

(3) From sodium formate: If this salt be heated to over 400° C. (752° F.), air being excluded as much as possible, it is converted into sodium oxalate, from which the acid can then be liberated as in the preceding method. The yield of acid amounts to 50 per cent. and more of the weight of sodium formate used. Sodium formate is produced readily by heating sodium hydroxide with carbon monoxide to 100° C. (212° F.); thus, $NaOH + CO = NaHCO_2$.

Purification.—For the purpose of volumetric analysis the U. S. Pharmacopœia directs oxalic acid which leaves a residue on ignition, or on solution in water, to be puri-

fied as follows: To 1 part of the acid add 10 parts of cold water, and shake until the latter is saturated.

Properties.—Oxalic acid crystallizes from its aqueous solution in flat, oblique, rhombic prisms, which are colorless, transparent, inodorous, of a strongly acid taste and reaction, effloresce when warmed, and are soluble in about 10 parts of water at ordinary temperature, and in nearly all proportions of boiling water. Nitric acid increases their solubility in cold water. They dissolve in $2\frac{1}{2}$ parts of cold and 1.8 parts of boiling strong alcohol, and are but little soluble in ether. Oxalic acid fuses at 98° C. (208.4° F.), and at about 160° C. (320° F.) sublimes partly unaltered, and is partly decomposed into carbonic anhydride and carbon monoxide without residue. The same decomposition takes place when oxalic acid is heated with strong sulphuric acid, but when dissolved in the latter at a moderate heat large oblique octahedra of anhydrous oxalic acid are deposited gradually. The commercial acid usually leaves upon platinum-foil a little charcoal, which finally is consumed, a small residue of alkali carbonate often remaining. Heated with glycerin to a little above the temperature of boiling water, it is decomposed into carbonic and formic acids. In chemical affinity it is one of the strongest acids, yielding normal and acid salts, which, with the exception of the normal alkali oxalates, are mostly insoluble or slightly soluble in water, but which dissolve in diluted nitric acid. Oxalic acid yields with lime-water, and the soluble oxalates with all soluble calcium salts, a white precipitate which is insoluble in oxalic and acetic acids. The acid potassium oxalates are popularly called *salt of sorrel*, also *salt of lemon*, and are employed for removing iron stains from paper, linen, leather, etc.; but at present oxalic acid is usually substituted for this purpose.

Tests.—Mineral impurities are left behind on incinerating oxalic acid upon platinum-foil; organic impurities will blacken concentrated sulphuric acid on boiling. Sulphuric acid, if present, will produce with barium nitrate a white precipitate which is insoluble in diluted nitric acid.

Action and Uses.—Oxalic acid is practically never employed in medicine. It has been recommended for asthma, chronic bronchitis, amenorrhœa, and cystitis, but is rarely given in these conditions on account of its poisonous properties. The drug is a good antiseptic, and is used by many surgeons to disinfect the hands. Oxalic acid has been frequently dispensed in error for magnesium sulphate, but may be easily distinguished from the latter by its sour taste.

In overdose, especially when given in concentrated solution, it occasions violent gastro-enteritis. There is a sensation of constriction and burning pain in the throat and stomach. Vomiting usually occurs, the ejected matter being dark colored and at times containing blood. The severe pain usually causes collapse, which passes into drowsiness, stupor, and death. When given in dilute solution it produces death by depressing the heart and central nervous system. It produces little pain or irritation, but softens the tissue with which it comes in contact. Death may occur within half an hour or the patient may live a number of days. The urine, after a poisonous dose has been taken, frequently abounds in oxalates, and glycosuria may be present. Very large doses may cause early emesis, and under these circumstances recovery is not uncommon. It is stated that 1 drachm (4 Gm.) is the minimum fatal dose. The antidote to oxalic acid is chalk or magnesia mixed with water. Potassa and soda are not antidotes because they are soluble oxalates and equally as poisonous as the acid. Unless prompt treatment is instituted the patient usually dies. The use of a stomach-tube is advantageous. If seen early, emetics may be employed. Should collapse occur, the maintenance of a prone position, the application of external heat, and the administration of circulatory and respiratory stimulants are essential.

The dose of oxalic acid is stated to be from $\frac{1}{4}$ to $\frac{3}{4}$ of a grain (0.015–0.045 Gm.). It should be well diluted with water, and may be repeated every three or four hours.

ACIDUM PHOSPHORICUM, *U. S.*, *P. G.*—Phosphoric Acid.

Acidum phosphoricum concentratum.—*Concentrated Phosphoric Acid*, Br.—*Acide phosphorique*, Fr.; *Phosphorsäure*, G.; *Acido phosphorico*, It., Sp.

Formula, $H_3PO_4 = PO.(OH)_3$. Molecular weight, 97.29.

Official phosphoric acid of the different pharmacopœias is not of uniform strength, that of the U. S. P. has the specific gravity 1.707, and contains 85 per cent. of absolute

H_3PO_4; that of the Br. P. the specific gravity 1.5, and contains 66.3 per cent. of H_3PO_4, and that of the G. P. contains only 25 per cent. of the absolute acid and has the specific gravity 1.154.

History and Origin.—This is the principal acid of the element phosphorus, and was discovered by Marggraf in 1757. Phosphorus occurs in nature almost exclusively in the form of phosphates, principally of calcium (phosphorite, opatite, etc.), aluminum, and iron. The greatest beds of phosphate rock (essentially calcium phosphate) are in Florida. Phosphates are an essential constituent of fertile soils, and are indispensable for the development of seeds. They occur abundantly in urine, blood, and bones. Bone-ash is almost wholly calcium phosphate. During the last twenty years the slags from iron and steel furnaces have become a source of phosphates and phosphoric acid.

Preparation.—For pharmaceutical purposes the acid should always be made from phosphorus. Several methods may be employed:

Phosphorus heated with nitric acid of sufficient strength is oxidized rapidly to phosphoric acid; thus, $5HNO_3 + 3P + 2H_2O = 3H_3PO_4 + 5NO$. Care should be taken to control the reaction and to insure full oxidation of the phosphorus, and removal of all nitric acid and decomposition-products in the final product. 1 part of phosphorus requires about 3½ parts of concentrated nitric acid. The phosphorus and a portion of the acid diluted with an equal weight of water are introduced into the tubulated retort, which is heated on a water-bath. The nitric acid that distils over is caught in a cooled receiver and returned to the retort. As the first reaction grows weaker, more nitric acid is added in small quantities. Finally the contents of the retort are evaporated in a porcelain dish up to a temperature of 190° C. (374° F.) to drive out nitric acid, a portion is diluted and tested with potassium permanganate for phosphorous acid. The color should not disappear within a minute, otherwise more nitric acid must be added and the liquid heated again.

Markoe (*Proc. Am. Pharm. Assoc.*, 1875) proposed a process which is used on a large scale. 540 parts of distilled water are placed in a large jar which is surrounded by ice, 90 parts of phosphorus and 1 part of iodine are added and stirred to bring both in thorough contact. 6 parts of bromine are now run in from a stoppered separatory funnel, *drop by drop*, and in such manner that each drop comes in contact with phosphorus, so that no accumulation of bromine may occur. After the reaction is over, 540 parts of nitric acid (specific gravity 1.42) are added and the vessel covered with a plate. The action goes on slowly for 24 hours or so, and needs no care. After the phosphorus has disappeared the liquid is treated as in the above process. While the iodine assists the chemical change somehow, the essential reactions occur between phosphorus, bromine, and nitric acid; thus, (1) $P + 5Br = PBr_5$. (2) $PBr_5 + 4H_2O = H_3PO_4 + 5HBr$. (3) $3HBr + HNO_3 = 3Br + 2H_2O + NO$. The reactions are cyclic, and bromine acts merely as a medium for carrying oxygen from the nitric acid to the phosphorus.

Phosphoric acid prepared from phosphorus nearly always contains arsenic; this should be removed by diluting and warming the acid, saturating it with hydrogen sulphide, and letting it stand corked in a warm place for 24 hours. Arsenic sulphide is filtered off and the acid concentrated by heat again.

For use in the arts and in the manufacture of phosphates, where a chemically pure acid is not required, the acid is made from bone-ash by treatment with sulphuric acid, by which insoluble calcium sulphate is formed and phosphoric acid; thus, $Ca_3(PO_4)_2 + 3H_2SO_4 = 3CaSO_4 + 2H_3PO_4$. After filtering off and washing the sulphate the filtrate is evaporated to a small volume, any additional sediment of calcium sulphate filtered off, and the liquid then heated to 320° C. (608° F.) until any sulphuric acid present is volatilized.

Another method is to treat the filtrate from calcium sulphate with sodium carbonate, to form sodium phosphate, which is then precipitated as barium phosphate. The latter is treated with a calculated quantity of sulphuric acid, when phosphoric acid is set free; thus, $Ba_3(PO_4)_2 + 3H_2SO_4 = 3BaSO_4 + 2H_3PO_4$. The barium sulphate is quite insoluble.

Bone-ash phosphoric acid is always contaminated with calcium salts and often with sulphates, and hence is unsuitable for medicinal purposes.

The following table, incorporated in the U. S. P., shows the specific gravity of phosphoric acid at 15° and 25° C. (59° and 77° F.), and also the quantity of normal KOH solution required to neutralize 1 Cc. of the acid of different strengths:

Per cent. phosphoric acid.	Specific gravity— $\frac{25°\ C.}{25°\ C.}$	Specific gravity— $\frac{15°\ C.}{15°\ C.}$	Correction of specific gravity for 1° C.[1]	Fractional per cent.[2]	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc. normal KOH.

Phosphoric acid may also be made by burning phosphorus in air in a suitable apparatus, dissolving the resulting pentoxide in water or in very dilute nitric acid and heating for a long time: $2P + 5O = P_2O_5$; $P_2O_5 + 3H_2O = 2H_3PO_4$.

Properties.—Phosphoric acid, U. S. P., is a colorless inodorous strongly acid liquid, miscible with water and alcohol in all proportions. If evaporated at a temperature not exceeding 160° C. (320° F.), a syrupy liquid is obtained, which gradually on standing, more rapidly on the addition of a crystal of phosphoric acid, yields colorless, flattish, hexagonal prisms, melting at about 40° C. (104° F.), deliquescing in a damp atmosphere and completely soluble in alcohol and in water. The syrupy acid does not act on animal and vegetable matter like sulphuric or other mineral acids. At 200° C. (392° F.) it begins to change to pyrophosphoric acid. At a still higher temperature it is converted into metaphosphoric acid, which volatilizes in dense fumes, or, on cooling, forms a transparent mass of glacial phosphoric acid.

The salts of orthophosphoric acid, with the exception of those of the alkalies, are mostly insoluble in water; the insoluble ones dissolve in nitric acid, likewise in acetic acid, with the exception of the phosphates of lead, iron (ferric), uranium, and aluminum. The solution of an orthophosphate rendered alkaline by ammonia yields a white precipitate with a mixture of magnesium and ammonium salts. This precipitate is insoluble in ammonia, sparingly soluble in water, freely soluble in acids, and at a red heat is converted into magnesium pyrophosphate; this reaction is used often for the gravimetric estimation of phosphoric acid. For its volumetric estimation the U. S. Pharmacopœia prescribes titration with normal alkali solution, using phenolphthalein as an indicator, as follows: 10 Gm. of the acid are diluted to 100 Cc. 9.73 Cc. of the diluted acid (containing 0.973 Gm. of H_3PO_4), when mixed with 10 Cc. of a cold saturated solution of potassium chloride, should require for neutralization not less than 17 Cc. of normal potassium hydroxide solution. Phosphoric acid, being tribasic, is capable of forming three classes of salts with the alkalies—namely, primary, secondary, and tertiary—the first having a distinctly acid reaction; the second, neutral or only slightly alkaline; and the last, a strongly alkaline reaction. Complete neutralization, therefore, can not be aimed at, as the normal phosphate itself would affect the indicator; and since different indicators show different behavior with the primary and secondary phosphates, it is important to know at which point the end-reaction occurs. With phenolphthalein the point of neutrality is observed as soon as two-thirds of the acid present have combined to form dipotassium-hydrogen phosphate, K_2HPO_4, while with methyl-orange and Congo-red the change occurs when one-third of the acid has combined, forming monopotassium-hydrogen phosphate, KH_2PO_4. This peculiar behavior necessitates different calculations as the respective color indicators

are used; with phenolphthalein each Cc. of normal KOH solution represents 0.04865 Gm. of H_3PO_4, whereas with methyl-orange the value of each Cc. is increased to 0.0973. The number of cubic centimeters of normal KOH solution, added in either case to produce the first permanent alkaline reaction, when multiplied by the respective factors, will indicate the total amount of orthophosphoric acid present in the weighed sample, and from this the percentage is readily calculated. In the above assay, each Cc. of alkali represents 5 per cent. of H_3PO_4.

The strength of medicinal phosphoric acid, which has been proved to be free from other acids and from salts, may be conveniently ascertained by combining with lead, using an excess of the pure oxide, evaporating to dryness, and igniting, when the increase of weight indicates the amount of phosphoric anhydride (Br.).

Acidum Phosphoricum Dilutum, U. S., Br.—*Diluted phosphoric acid,* E.; *Acide phosphorique médicinal,* Fr.; *Verdünnte Phosphorsäure,* G.—Mix phosphoric acid, 10 Gm., with distilled water, 75 Gm.—U. S. Or 1 part of acid may be mixed with 7.5 parts of water, all by weight. Mix concentrated phosphoric acid, 3 fluidounces, with distilled water, sufficient to make 20 fluidounces.—Br.

Diluted phosphoric acid corresponds in all respects to the preceding, except that it contains only 10 per cent. of H_3PO_4 (U. S.), 13.8 per cent. (Br.), and has the density of 1.057 (U. S.) or 1.08 (Br.). When 4.87 Gm. of this acid are diluted with 5 Cc. of a cold saturated solution of potassium chloride and titrated with normal alkali solution, 10 Cc. of the latter should be required before the alkaline end-reaction occurs, using phenolphthalein as an indicator, each Cc. corresponding to 1 per cent. of H_3PO_4 (U. S.). The British Pharmacopœia requires 1 Gm. of this acid to yield with 0.5 Gm. of oxide of lead a residue weighing 0.6 Gm. after heating to dull redness; 6 fluidrachms (Br.) of this acid correspond to 35.5 grains of P_2O_5 or 49 grains of H_3PO_4.

Fungous growths may appear in dilute phosphoric acid after a long time; a trace of hydrochloric acid will prevent this.

Impurities.—Pure glacial phosphoric acid dissolves completely in distilled water, and this solution is not precipitated on standing for 2 days, after having been saturated with hydrogen sulphide (arsenic, lead). When boiled for some time and then supersaturated with ammonia, no precipitate is produced, with the exception of a slight turbidity (calcium, magnesium), and the further addition of ammonium sulphide causes no change (iron and similar metals). With potassium hydroxide in excess ammonia is not evolved. If completely precipitated by lead acetate, the filtrate, after the excess of lead has been removed by hydrogen sulphide, leaves, on evaporation, only a very minute residue (potassium sodium). Official phosphoric acid must stand the following U. S. P. requirements: No dark-brown color should appear around a crystal of ferrous sulphate when dropped into a cooled mixture of 1 Cc. each of the acid and sulphuric acid (absence of nitric acid). 1 Cc. of the acid diluted with 5 Cc. of water and gently warmed should not be blackened by a few drops of silver nitrate test-solution, or rendered turbid by mercuric chloride test-solution (absence of phosphorous acid). After dilution with water (1 in 10), 5 Cc. should not respond to the modified Gutzeit's test for arsenic (see under Arseni Trioxidum). If phosphorous acid be present, the same preliminary treatment should be applied as is described under Acidum Hypophosphorosum. No turbidity should appear upon mixing 1 Cc. of the acid, 3 Cc. of alcohol, and 1 Cc. of ether (absence of phosphates). 10 Cc. of the acid diluted with water (1 in 20), when acidulated with 1 Cc. of diluted hydrochloric acid, should not be colored or rendered turbid by the addition of an equal volume of fresh hydrogen sulphide test-solution, after being corked at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). The acid diluted with 5 volumes of water, tested in separate portions, should not yield a precipitate with barium chloride test-solution (absence of sulphuric acid), or with silver nitrate test-solution (absence of hydrochloric acid), or when dropped into albumin test-solution (absence of metaphosphoric acid), or by the addition of an equal volume of official tincture of ferric chloride, even after several hours (absence of pyrophosphoric and metaphosphoric acids). The official diluted acid should conform to the reactions and tests given above for phosphoric acid.

Action and Uses.—Dilute phosphoric acid is very generally employed in medicine. It is a tonic and stimulant to the gastric mucous membranes, acts as a synergist to pepsin,

and aids in the formation of peptones. It does not act as phosphorus; and the animal tissues cannot produce phosphorus compounds either from the acid or the inorganic phosphates. It may be given with advantage in nervous exhaustion and in certain forms of dyspepsia. Phosphoric acid is recommended in melancholia, hysteria, diabetes, the low fevers, and in jaundice, but it is probable that hydrochloric or nitric acid may be given to better advantage. It has been used to control the night-sweats of phthisis, but other more valuable remedies have largely replaced it. The dose of the pure acid is stated to be from 2 to 8 minims (0.10–0.50 Cc.), largely diluted with water; of the dilute acid, from 20 minims to 1 drachm (1.30–4 Cc.), in water, are usually given at a dose.

Related Acids.—1. ACIDUM METAPHOSPHORICUM.—*Metaphosphoric acid, Glacial phosphoric acid*, E.; *Acide phosphorique glaciale*, Fr.; *Metaphosphorsäure, Glasige Phosphorsäure*, G. HPO_3.—Thomas Graham, 1833, showed that the relation between meta-, pyro-, and orthophosphoric acids was one involving different degrees of hydration of P_2O_5, as shown in the equations: $P_2O_5 + H_2O = 2HPO_3$, metaphosphoric acid; $P_2O_5 + 2H_2O = H_4P_2O_7$, pyrophosphoric acid; $P_2O_5 + 3H_2O = 2H_3PO_4$, orthophosphoric acid. By dissolving P_2O_5 in cold water, the meta acid is formed, which, on boiling a long time, or heating with a small quantity of nitric acid, changes to the ortho acid by addition of water. Conversely, by heating the ortho acid above 300° C. (572° F.) it passes to the meta acid by loss of water. The meta acid is also formed by heating ammonium orthophosphate, $(NH_4)_2HPO_4 = 2NH_3 + H_2O + HPO_3$. Pure metaphosphoric acid is a white sticky mass. The commercial "glacial" phosphoric acid is a hard white transparent substance which contains an admixture of sodium metaphosphate to give it hardness and transparency. The glacial acid occurs in sticks or glassy lumps, the latter, as a rule, being purer than the sticks. Besides the sodium salt, it also contains varying quantities of the pyro acid. The acid is easily soluble in water, gradually changing into phosphoric acid. It is hygroscopic. The method of preparation is as follows: About equal parts of bones burned to whiteness, and sulphuric acid diluted with 15 parts of water, are digested until the insoluble part has been converted into white smooth calcium sulphate; the liquid, containing sulphuric and phosphoric acids and holding calcium and magnesium phosphates in solution, is removed by filtration and washing with water, neutralized with ammonia or ammonium carbonate, separated from the precipitated phosphates, and evaporated to dryness. The ammonium phosphate is then heated in a platinum crucible to redness until the ammonia has been completely driven off. Porcelain capsules are corroded in this last operation. The fused acid is poured upon polished iron plates, and, when cool, put into bottles. Thus prepared, phosphoric acid contains a little sodium (from the bone ash), to free it from which Neustadtl proposed to neutralize the acid with ammonia, precipitate with barium chloride, and decompose the resulting barium phosphate after it has been thoroughly washed, with sulphuric acid; the acid filtrate is then evaporated and heated to redness.

2. ACIDUM METAPHOSPHORICUM DILUTUM, N. F.—*Diluted glacial or metaphosphoric acid.*—Glacial phosphoric acid, 100 Gm.; distilled water, sufficient to make 1000 Cc.; dissolve without the aid of heat. When prepared from pure glacial acid this preparation contains about 10 per cent. of metaphosphoric acid. It should be kept in a cool and dark place, and not too large quantities should be prepared. Whenever iron pyrophosphate (U. S. P.) forms one of the ingredients of a mixture containing diluted phosphoric acid, the official acid is unsuitable, as it produces with the salt a gelatinous precipitate. If a clear mixture is required, the above preparation is to be used in place of the official. The same is true of phosphate of iron (U. S. P.), though here, under certain conditions, no precipitate may occur with phosphoric acid (N. F.).

3. ACIDUM PYROPHOSPHORICUM.—*Pyrophosphoric acid*, E.; *Acide pyrophosphorique*, Fr.; *Pyrophosphorsäure*, G. $H_4P_2O_7$.—Obtained by heating syrupy phosphoric acid in a platinum dish to 230°–250° C. (446°–482° F.) until a portion, neutralized with ammonia water, gives a pure white precipitate with silver nitrate. It is a white, hygroscopic, glassy mass, or indistinct opaque crystals. An aqueous solution is permanent for about a year; heating it converts the pyro acid into ortho acid. The insoluble salts of meta- and pyrophosphoric acids are mostly soluble in dilute acids. Ferrous and ferric, mercurous, copper, zinc, lead, and silver pyrophosphates dissolve also in a solution of sodium pyrophosphate.

The following tests will serve to distinguish the three varieties of phosphoric acid from each other:

Acid.	Egg-albumen (free acid).	Silver nitrate (acid neutralized with ammonia).	Magnesia mixture (acid neutralized with ammonia).
HPO_3.	Coagulation.	White precipitate.	No precipitate.
$H_4P_2O_7$.	No coagulation.	White precipitate.	No precipitate.
H_3PO_4.	No coagulation.	Yellow precipitate.	White precipitate.

ACIDUM PICRICUM.—Picric Acid.

Acidum carbazoticum.—*Carbazotic* or *Nitrophenisic acid, Trinitrophenol*, E.; *Acide picrique, carbazotique, nitroxanthique*; *Jaune-amer*, Fr.; *Pikrinsäure, Trinitrocarbolsäure, Welter'sches Bitter*, G.; *Acido picrico*, Sp.

Formula, $C_6H_2(NO_2)_3OH$. Molecular weight, 227.41.

Origin and Preparation.—A solution of this compound, as obtained from indigo, was recognized as a dyeing material by Woulfe (1771). Hausmann (1788) prepared picric acid from the same material as a bitter mass; Welter (1799) obtained it in crystals from silk, and subsequently its composition was investigated by Liebig, Dumas, and others. It can be obtained by the action of nitric acid upon salicin and its derivatives, phloridzin, indigo, aloes, benzoin, silk, and other substances, and may be prepared on a large scale by mixing equal parts of phenol and sulphuric acid of 1.84 specific gravity, and, after the formation of phenolsulphonic acid has been completed, adding nitric acid of 1.34 specific gravity in a thin stream and with constant stirring of the mixture as long as nitrous fumes are given off. The mixture having cooled and congealed to a crystalline mass, is freed from adhering acid in a centrifuge and dissolved in solution of sodium hydroxide. After filtration the solution of sodium picrate is decomposed by means of hydrochloric acid and the precipitated picric acid is purified by recrystallization from hot water. The reactions involved in the preparation of the acid may be expressed thus: $C_6H_5OH + H_2SO_4 = C_6H_4(SO_3H)OH$ (phenolsulphonic acid) $+ H_2O$ and $C_6H_4(SO_3H)OH + 3HNO_3 = C_6H_2(NO_2)_3OH$ (picric acid) $+ H_2SO_4 + 2H_2O$.

Picric acid is officially recognized in the French Pharmacopœia.

Properties.—Picric acid crystallizes in bright-yellow, inodorous needles or scales, which melt at 122.5° C. (252.5° F.), and when cautiously heated sublime without decomposition, forming yellow suffocating vapors which condense again to crystals; but on being rapidly and strongly heated in a test-tube picric acid is decomposed with detonation, while upon platinum-foil it burns with a sooty flame, without residue. It has an acid and extremely bitter taste, dissolves at 5° C. (41° F.) in 160 parts, at 15° C. (59° F.) in 86 parts of water, and in 25 parts of boiling water, forming a bright-yellow solution, and is readily soluble in alcohol, ether, chloroform, benzene, and petroleum benzin. Its solutions stain the skin and other organic matter permanently yellow; hence its use in dyeing. The aqueous solution precipitates gelatin. It unites with bases, forming salts which are mostly yellow, crystallizable, have a bitter taste, and are explosive by percussion or when heated. Ammonium picrate, $C_6H_2(NO_2)_3ONH_4$, occurs in yellow needle-shaped crystals, readily soluble in cold water.

Tests.—The above-described properties are sufficient for recognizing the acid. Its purity is shown by the complete solubility in the solvents mentioned before. On heating an aqueous solution of picric acid with chlorinated lime, very pungent and irritating vapors of the so-called *chloropicrin* are given off—a compound more properly known as *nitrochloroform* and *nitrotrichlormethane*, $C(NO_2)Cl_3$.

Pharmaceutical Uses.—A solution of 1 part of picric acid in 100 parts of water forms a convenient test for alkaloids, nearly all of which are precipitated from their diluted acidulated solutions, except aconitine, caffeine, cocaine, coniine, hyoscyamine, morphine, and theobromine.

Picric acid is much employed for dyeing wool and silk yellow, also for staining wood.

Action and Uses.—Picric acid is given with apparently little advantage in medicine, and for this reason is rarely used. It is claimed that the drug is an antiseptic and analgesic, and solutions of varying strength, locally applied, have been recommended in fungous endometritis after the employment of the curette and as a lotion in the treatment of erysipelas, lymphangitis, and fissured nipples. Picric acid is a very useful application for burns. It should be used by soaking lint in a solution containing $1\frac{1}{2}$ drachms of the acid, 2 ounces of alcohol, and 2 pints of water. Ammonium picrate was formerly employed in trichiniasis and in intermittent fevers, but experience has shown it to be of little or no value in either condition. Large amounts of the acid or its salt are irritant, causing gastro-intestinal inflammation, nausea, vomiting, and purging, followed by collapse, convulsions, and death. It imparts a yellow color to all the tissues of the body and to the urine. The red blood-cells are partly dissolved, the white ones are increased in number and are said to contain numerous motile nuclei.

The dose of picric acid is from $\frac{1}{2}$ to 2 grains (0.025–0.10 Gm.); that of the ammonium salt $\frac{1}{2}$ a grain (0.025 Gm.) three times daily.

ACIDUM SALICYLICUM, *U. S., Br., P. G.*—Salicylic Acid.

Acidum Spiricum.—*Ortho-oxybenzoic acid*, E.; *Acide salicylique*, Fr.; *Salicylsäure, Spirsäure, Spiroylsäure, Salicoylsäure*, G.; *Acido salicilico*, It., Sp.

Formula, $HC_7H_5O_3$ or $C_6H_4.OH.COOH$. Molecular weight, 137.01.

Origin and Formation.—Salicylic acid occurs in the free state in the flowers of *Spirwa Ulmaria*, and as methyl salicylic acid ester in the leaves of *Gaultheria procumbens* and *Andromeda Leschenaultii*, and is formed from salicin, indigo, and some other organic matters by adding them to potassium hydroxide heated to fusion. It was discovered by Piria (1838) as a derivative of salicin; its presence in oil of wintergreen was proved by Procter (1848), and in several species of *viola* by Mandelin (1881).

Preparation.—It is extensively prepared from phenol, according to a method first suggested by Kolbe in 1874. As the first step, dry sodium carbolate is prepared, which is introduced into a retort; dry carbon dioxide is passed through it while heat is applied, gradually increased from 100° to 220° C. (212°–428° F.), and not over 250° C. (464° F.). By this operation carbon dioxide is made to enter into the molecule of phenol, producing disodium salicylate, while one-half of the phenol distils over: $2C_6H_5ONa + CO_2 = C_6H_4ONaCOONa + C_6H_5OH$. The residue in the retort is now dissolved in boiling water, filtered if necessary, and decomposed by hydrochloric acid, when, on cooling, impure salicylic acid, having a brown or reddish-brown color, is precipitated in the form of a crystalline powder; this reaction occurs as follows: $Na_2C_7H_4O_3 + 2HCl = 2NaCl + C_6H_4OHCOOH$ (salicylic acid), sodium chloride remaining in solution. The impure acid thus obtained is further purified by converting it into calcium salicylate by neutralizing with calcium carbonate, and decomposing the newly formed salt again with hydrochloric acid. Impure salicylic acid may also be purified by sublimation in a current of superheated steam or by dialysis of a hydro-alcoholic solution.

C. Schmitt (1885) showed that dry sodium carbolate treated under pressure in the cold with CO_2 yields sodium phenylcarbonate, $C_6H_5ONaCO_2$, which when heated to 120°–140° C. (248°–284° F.) is changed to monosodium salicylate, $C_6H_4OHCO_2Na$, by molecular rearrangement, without loss of phenol. From this salt salicylic acid may then be obtained by the usual methods of decomposition and purification. This process has been patented and is probably now used in place of the original synthetic method for economical reasons. Contact with iron or with materials containing iron is to be avoided, since a reddish color is thereby imparted.

Salicylic acid is obtained on a limited scale, commercially, direct from oil of wintergreen, by boiling the latter with potassium hydroxide solution, whereby potassium salicylate is formed, methyl alcohol being liberated; thus, $C_6H_4OHCOOCH_3 + KOH = C_6H_4OHCOOK + CH_3OH$. The alcohol may be recovered by distillation, and the potassium salicylate decomposed in solution by hydrochloric acid, the liberated salicylic acid being washed with cold water and recrystallized from hot solution. Such acid is sold as natural salicylic acid, and commands a much higher price than the synthetic acid.

Properties.—Thus obtained, salicylic acid is in small acicular crystals, white, inodorous, of a sweetish, acidulous, somewhat acrid taste, and of the specific gravity 1.45. The commercial article occasionally has a yellowish or brownish tinge and a slight odor. It fuses at 156°–157° C. (312.8°–314.6° F.), and if carefully heated sublimes unaltered, without boiling, and without leaving more than 0.6 per cent. of fixed residue, at about 200° C. (392° F.). When rapidly heated to between 220° and 230° C. (428° and 446° F.), it is decomposed into carbon dioxide and phenol: $C_6H_4OHCOOH$ yields $CO_2 + C_6H_5OH$. It is soluble in 450 parts (500 parts, Br. and P. G.) of water at 15° C. (59° F.), 308 parts at 25° C. (77° F.), U. S., and in 14 parts, U. S. (15 parts, Br. and P. G.), of boiling water. The hot solution when slowly cooled yields long, slender needles. The solubility in water is considerably increased by the addition of phosphates, citrates, and acetates of the alkalies, and of borax, the solution made with the latter gradually acquiring a bitter taste. It dissolves freely at ordinary temperatures in wood spirit, in 2 parts of absolute and 2.4 parts of 90 per cent. alcohol, in 3.5 parts of amyl alcohol, in 2 parts of ether, in 80 parts of chloroform, in 80 parts of benzene, in 60 parts of fixed oils, and in 20 parts of glycerin. Its solution in 5 parts of boiling oil of turpentine congeals on cooling. C. Becker (1875) observed that 1 part of salicylic acid and 2 parts of olive oil, heated together, formed a homogeneous mixture. On adding to a small portion of salicylic acid, in a test-tube, about 1 Cc. of concentrated sulphuric

acid, and then cautiously about 1 Cc. of methyl alcohol in drops, on heating the mixture to boiling the odor of oil of gaultheria will be evolved. With borax a crystallizable union is obtained, $NaC_7H_5O_3 + C_7H_5(BO)O_3$, of acid reaction (Prescott). With half its weight of borax and two and a half times its weight of glycerin, a 25 per cent. solution of salicylic acid may be obtained. The alcoholic solution, evaporated spontaneously, yields the acid in large oblique, quadrangular prisms. The aqueous or alcoholic solutions acquire a deep-violet color with ferric chloride, provided alkalies, alkaline salts, and most acids are absent. The aqueous solution yields with bromine water a crystalline precipitate sparingly soluble in water, and when boiled with Millon's reagent of mercuric nitrate gives a red color. A blood-red color, changing to brown and black, is produced by adding an excess of sulphuric acid to a mixture of salicylic acid and sugar, and applying a gentle heat. Sulphate of copper produces an emerald-green color in very dilute solutions of normal salicylates or salicylic acid. Potassium chlorate and hydrochloric acid convert it, like phenol, quinone, and allied compounds, into *chloranil* or tetrachloroquinone, $C_6Cl_4O_2$, which forms yellow crystals soluble in ammonia with a deep-red color. Salicylic acid effervesces with carbonates, behaving as a monobasic acid ; but under certain circumstances a second hydrogen atom may be replaced by metals, as in the case of disodium salicylate mentioned above. Combined with alkalies, the solution of salicylic acid turns brown in contact with the air. On dry distillation the salicylates are decomposed, yielding carbon dioxide and phenol.

Tests.—Salicylic acid should be absolutely free from the odor of phenol, the presence of which lowers its melting-point. If 0.5 Gm. of the acid be dissolved in 10 Cc. of a 10 per cent. sodium carbonate solution, the liquid shaken with an equal volume of ether, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of phenol. A 5 per cent. alcoholic solution of the acid, acidified with nitric acid, should not be affected upon addition of silver nitrate test-solution, showing the absence of hydrochloric acid. Heated upon platinum-foil, salicylic acid should evaporate without residue (mineral impurities). It should dissolve in cold concentrated sulphuric acid without imparting any or only a faint-yellow color (organic impurities). Kolbe (1876) has given the following practical test: It should be completely soluble in absolute alcohol, and the solution, if allowed to evaporate spontaneously in a glass or porcelain dish in a place protected from dust, should yield a white residue of aggregated crystals, the points of which are colorless and transparent. In the presence of iron the ends will be reddish or purplish, and with organic coloring-matter will appear yellowish or brown.

Two other oxybenzoic acids are known, which melt at 200° and 210° C. (392° and 410° F.) and do not give a violet-red color with ferric chloride. The para-acid is more freely soluble than the others, and is obtained in Kolbe's process for salicylic acid by using potassium instead of sodium carbolate and increasing the heat to above 150° C. (302° F.).

Action and Uses.—When locally applied to mucous membranes in concentrated form, salicylic acid acts as a decided irritant. When taken internally it is capable of causing ulceration of the buccal mucous membrane and nausea and vomiting, and if continuously applied to the skin, it may cause slight corrosion of this tissue also. Solutions of the acid or its salts usually have a less harmful effect, and do not cause to so marked a degree the irritation which follows the employment of the powdered drug.

Solutions of salicylic acid are germicidal, and may be employed interchangeably with those of carbolic acid ; the consensus of opinion, however, is that the latter drug is more efficacious. The drug is also antifermentative, and impedes not only the digestive ferments and those of putrefaction, but also carbonic and acetic acid formation.

In moderate amounts salicylic acid decreases reflex action, causes roaring in the ears, vertigo, and occasionally headache. In overdose these symptoms are exaggerated ; profuse sweating, partial or complete blindness, ptosis or complete paralysis, and deafness or impairment of hearing may also occur. Medicinal quantities exert no powerful influence upon the circulation, but may be considered depressant rather than stimulant. It is thought by some that a primary increase in blood-pressure occurs, but that this is soon followed by dilatation of the peripheral capillaries. See below.

Salicylic acid materially lowers the temperature in fevered states, but has only a slight influence upon the normal bodily heat. This may be due in part to the profuse sweats which follow its use, but in the author's opinion the fall is chiefly caused also by its effect upon the centers governing the heat mechanism of the body.

It is generally conceded that the drug is rapidly absorbed as a salicylate, and that its elimination begins in from fifteen to thirty minutes. The urine becomes olive green when poisonous doses are taken, due to the presence of indican and pyrocatechin. Salicylic acid increases the percentage of urea in the urine, and it is eliminated by the kidneys as salicyluric acid.

Ordinary doses of the drug increase the depth and rapidity of respiration. This is probably due to stimulation of the respiratory center and the peripheral pulmonary vagi. Poisonous doses produce death by respiratory paralysis.

The drug is considered by some as an hepatic stimulant, but it is practically never employed for this purpose.

Salicylic acid was first employed in medicine as an antiperiodic and antipyretic, but as it is much inferior to quinine and the coal-tar derivatives it is rarely used when these drugs are indicated. It is of more benefit in the treatment of rheumatic fever than any other drug, as it reduces the temperature, relieves the pain, and frequently shortens the course of the disease. It prevents the cardiac and joint complications only by shortening the duration of the disease, and not by any specific action upon these parts. The drug may be employed with benefit in quinsy occurring in persons with a rheumatic diathesis and for the nervous irritability which sometimes occurs in gouty or lithæmic patients. Lumbago and sciatica sometimes succumb to its administration, and migraine, especially in gouty persons, is frequently cured by its use. It has been recommended in gastric dilatation when sarcinæ are present, in paroxysmal gastralgia, and for the removal of round worms.

A dusting-powder containing an equal amount of starch is beneficial in bromidrosis A 20 per cent. ointment sometimes relieves pruritus ani and vulvæ. In the treatment of corns a saturated solution applied upon lint is very serviceable, or 30 grains (2 Gm.) of the acid and 5 grains (0.3 Gm.) of extract of cannabis indica may be dissolved in ½ fluidounce (16 Cc.) of collodion and painted over the corn with a camel's hair brush.

The dose of the drug is from 5 to 20 grains (0.30–1.3 Gm.) every 4 hours until its physiological effects are observed.

Allied Compounds and Derivatives.—ACETYLSALICYLIC ACID. *Aspirin.* $C_6H_4COOHCO_2CH_3$.—A compound obtained by heating salicylic acid with acetyl chloride or acetic anhydride to 150° C. (302° F.) in a flask provided with a reflux condenser. It occurs in colorless crystals, of acidulous taste and melting at 135° C. (275° F.), not very soluble in cold water, but readily in alcohol, ether, and chloroform. Aspirin may be distinguished from salicylic acid by adding ferric chloride to an aqueous or alcoholic solution; no violet color should appear. It should not be confounded with salicyloacetic acid, occurring in glassy scales and used as an antiseptic. Aspirin may be employed as a substitute for salicylic acid in the treatment of rheumatic fever. It is stated that the drug is less likely to produce tinnitus than the latter remedy. It has also been recommended as an intestinal antiseptic. The dose is from 10 to 15 grains (0.60–1 Gm.) 3 times daily.

HOMOSALICYLIC ACID. *Cresotic acid, Oxytoluic acid.* $C_6H_3CH_3OHCOOH$.—Three varieties of this acid occur—ortho-, meta-, and paracresotic acid, homologous with the three oxybenzoic acids. They may be prepared from the isomeric cresols by a process similar to that for synthetic salicylic acid. The acids occur in long, prismatic crystals, dissolve readily in alcohol, ether, and chloroform, but less so in hot water, and only with difficulty in cold water. The paracresotic acid is the only one that has met with much favor among physicians; its melting-point is at 151° C. (304.8° F.); it has been used as a sodium salt in the form of a finely crystalline powder, soluble in 24 parts of warm water, and possessing a bitter but not repulsive taste. Cresotic acid is never employed in medicine alone, but its sodium salt is said to possess antipyretic properties, and may be prescribed in doses of 30 to 60 grains (2–4 Gm.).

PHENYLSALICYLIC ACID. *Oxydiphenylcarbonic acid.* $C_6H_5.C_6H_3.OH.COOH$.—A white powder, freely soluble in alcohol, ether, and glycerin, but sparingly in water, and obtained by dry distillation of a mixture of calcium benzoate and salicylate, the resulting oxydiphenylketone being fused with potassium hydroxide. Phenylsalicylic acid has been recommended as an antiseptic dusting-powder.

SALICYLOUS ACID. *Salicylaldehyde, Oxybenzaldehyde, Oil of spiræa.* $C_6H_4OH.CHO$.—Occurs naturally as a constituent of various species of *Spiræa*, notably *Spiræa ulmaria*, meadow sweet. It is prepared synthetically by boiling a solution of sodium carbolate with chloroform for some time, acidulating with sulphuric acid and distilling. From the distillate the salicylaldehyde is removed by acid sodium sulphite, washed with alcohol, treated with diluted sulphuric acid, and redistilled. It is a colorless liquid, of agreeable odor, pungent taste, and slight acid reaction, having the specific gravity 1.1725 and boiling at 196° C. (384.8° F.). Sparingly soluble in water, but readily in alcohol or ether. It is capable of forming salt-like compounds with the metals. Salicylaldehyde is said to possess diuretic and antiseptic properties. It is given in doses of 2 to 10 minims (0.10–0.60 Cc.) several times daily.

SALICYLURIC ACID. *Salicoylglycocoll.* $CH_2NH(C_7H_5O_2)COOH$.—When salicylic acid is taken into the system a part is excreted in the form of the above combination. If the urine be slightly acidulated with phosphoric acid and shaken with ether, the ethereal solution evaporated, and the residue heated to 150° C. (302° F.) in a current of air, salicyluric acid will be obtained. It forms colorless needle-shaped crystals, difficultly soluble in water.

SULPHOSALICYLIC ACID. *Salicyl-sulphonic acid.* $C_6H_3SO_3H.OH.COOH$.—Occurs as colorless acicular crystals, freely soluble in water and in alcohol. It is obtained by the action of sulphuric anhydride on salicylic acid, or by treating salicylic acid with strong sulphuric acid. Its chief use is as a delicate test for proteids of all kinds, albumin, peptones, globulins, and fibrin. 1 part of egg-albumin in 12,500 parts of water can be detected by this reagent. A dense, bulky white precipitate, which is not redissolved on boiling, is formed in all cases except albumoses and peptones, and in these the precipitate, which dissolves on boiling, reappears on cooling. Sulphosalicylic acid has been employed in the treatment of rheumatic fever, and it may be tried in the various other conditions in which *salicylic acid* is useful. The dose is said to be from 5 to 10 grains (0.30–0.60 Gm.).

SALITANNOL. $C_{14}H_{10}O_7$.—A condensation-product of salicylic and gallic acids, formed by the action of phosphorus oxychloride. It occurs as a white amorphous powder insoluble in water, ether, and chloroform, but soluble in solutions of caustic alkalies; also slightly soluble in alcohol. Salitannol, because of its non-poisonous properties, has been employed as a safe surgical antiseptic.

ACIDUM STEARICUM, *U. S.*—Stearic Acid.

Aeidum stearinicum.—Acide stéarique, Fr.; *Stearinsäure, Talgsäure,* G.

Formula, $HC_{18}H_{35}O_2$ or $CH_3(CH_2)_{16}COOH$. Molecular weight, 282.14.

Origin.—Stearic acid occurs widely diffused throughout the animal kingdom, combined with glycerin in the form of stearin (glyceryl tristearate), and constitutes the bulk of the more solid fats, such as suet and tallow. It is also found in many vegetable fats, notably in palm oil.

Preparation.—When tallow and similar fats are saponified by boiling with soda-lye, the stearin is decomposed, sodium stearate being formed with liberation of glycerin; thus, $C_3H_5(C_{18}H_{35}O_2)_3 + 3NaOH = C_3H_5(OH)_3 + 3NaC_{18}H_{35}O_2$. The soap formed is decomposed by heating with water and sulphuric or hydrochloric acid; by this means the fatty acids are set free, and will float on the aqueous liquid, whence they are removed. Upon cooling, the solid acid mixture is subjected to strong pressure, whereby the fluid acids, oleic, etc., are removed. The residue may be still further purified by dissolving in hot alcohol, when upon cooling the solid acids separate, the liquid acids remaining in solution. Stearic acid is also obtained on a large scale by decomposing tallow or suet with sulphuric acid or superheated steam under pressure, as in the manufacture of glycerin; the fats are readily split up, the glycerin going into solution in the condensed water and the fatty acids floating on top. They may then be removed and purified as explained above.

Properties.—Pure stearic acid occurs in white glistening needles or leaflets, is odorless and tasteless, and does not appear greasy to the touch. It dissolves in all proportions in boiling alcohol and ether, from which it separates on cooling. It melts at 69.2° C. (156.5° F.) to a colorless oil, which on cooling solidifies to a white crystalline mass. The commercial acid, which is contaminated with palmitic, oxystearic, and other solid fatty acids, should have a melting-point not lower than 56° C. (132.8° F.), and on cooling should congeal at 54° C. (129.2° F.). It is soluble in 45 parts of alcohol at 15° C. (59° F.), or 16.6 parts at 25° C. (77° F.), U. S. The presence of undecomposed fat is ascertained by boiling 1 Gm. of the acid with 0.5 Gm. of monohydrated sodium carbonate in 30 Cc. of water; the resulting solution while hot should not be more than faintly opalescent.

Pharmaceutical Uses.—Stearic acid is used in the manufacture of glycerin suppositories, in which it is combined with sodium carbonate, forming sodium stearate, which gives body to the mass.

ACIDUM SULPHANILICUM.—Sulphanilic Acid.

Para-amido-benzene-sulphonic acid, E.; *Acide Sulfanilique,* Fr.; *Sulfanilsäure,* G.

Formula, $C_6H_4.NH_2.SO_3H + H_2O$. Molecular weight, 189.74.

Preparation.—To 75 Gm. of concentrated sulphuric acid (specific gravity 1.836) in a 250 Cc. flask add in small portions and with agitation 25 Gm. of colorless aniline; then heat the mixture on an oil-bath to 180°–190° C. (356°–374° F.) about 3 hours, or until no more aniline is noticed, by its odor or cloudiness, when a little of the liquid

is poured into caustic soda solution. When this point is reached, pour the brown syrupy liquid into 500 Cc. of cold water, in which sulphanilic acid is precipitated as a gray crystalline powder. Filter and dry on porous plates. Purify by repeated recrystallization from hot water, and if necessary with the aid of animal charcoal.

The acid is a substitution-product of benzene in which the sulphuric acid residue replaces an atom of hydrogen in the benzene molecule, in the para position to the amido group, NH_2, as shown by the equation $C_6H_5NH_2 + H_2SO_4 = C_6H_4\begin{cases}NH_2\\SO_3H\end{cases} + H_2O$.

Properties.—Sulphanilic acid forms rhombic crystals which effloresce in dry air and become opaque. It is soluble in 115 parts of water at 15° C. (59° F.), more easily in hot water; insoluble in alcohol and ether. The aqueous solution of the acid has an acid reaction; ammonia and caustic alkalies form easily soluble salts. Nitrous acid in cold solution forms with sulphanilic acid diazo-benzene-sulphonic acid: $C_6H_4\begin{cases}NH_2\\SO_3H\end{cases} + NOOH = H_2O + C_6H_4\begin{cases}N=N-OH\\SO_3H\end{cases}$. The latter forms dyes (azo-dyes) with numerous phenolic bodies, for example, alpha-amidonaphthol (applied in water analysis as a delicate test for nitrites). This diazo reaction is of practical importance in the uses of sulphanilic acid.

Tests.—The crystals should be colorless and burn on platinum-foil without leaving a residue. An aqueous solution should not be changed by hydrogen sulphide or barium chloride.

Ehrlich's Diazo-reagent.—I. Sulphanilic acid, 5 Gm.; hydrochloric acid (25 per cent.), 50 Gm.; distilled water, 1000 Cc. II. Sodium nitrite, 0.5 Gm.; distilled water, 100 Cc. For use, mix 50 Cc. of I. with 5 Cc. of II. Diazo-benzene-sulphonic acid is formed in solution in the mixture. This reagent has diagnostic value in certain febrile diseases when applied in testing the urine. The test is known as

Ehrlich's Diazo-reaction.—10 Cc. of urine are shaken with 10 Cc. of the diazo-reagent and 2.5 Cc. of ammonia water (10 per cent.). A yellowish-red to red color may be produced, which is best seen in the foam of the urine. The colors are designated as egg-yellow, orange, orange-red, carmine, scarlet.

ACIDUM SULPHURICUM, *U. S.*, *Br.*—Sulphuric Acid.

Acidum Sulfuricum, P. A., P. G.—*Oil of vitriol*, E.; *Acide sulfurique, Huile de vitriol*, Fr.; *Schwefelsäure, Vitriolöl*, G.; *Acido solforico*, It.; *Acido sulfurico*, Sp.

Formula, H_2SO_4. Molecular weight, 97.35.

Sulphuric acid as recognized in the different pharmacopœias varies somewhat in strength, as follows: Not less than 92.5 per cent. of absolute H_2SO_4 and a specific gravity not below 1.826 at 25° C. (77° F.), U. S.; 98 per cent. of absolute acid and the specific gravity 1.843, Br.; 94–98 per cent. absolute acid and a specific gravity of 1.836–1.84, P. G.

History and Occurrence.—The acid was known at an early date to the alchemists, but its preparation by heating to a high temperature anhydrous "vitriol" (ferrous sulphate) was first described by Basil Valentine about 1440, who named it *oil of vitriol*. Lavoisier (1777) showed that it contained sulphur and oxygen; and Richter (1795) determined the percentage composition nearly correctly. Sulphuric acid occurs widely distributed in combination with metals, chiefly as calcium, magnesium, and barium salts. It sometimes, though rarely, occurs in the free state in volcanic waters. It also occurs free in salivary glands of some mollusks.

Preparation.—It cannot be prepared from its salts, but must be made from sulphur dioxide, SO_2. It is best prepared on the large scale, and is manufactured in enormous quantities, the greatest portions being made in England and the United States. Sulphur dioxide, nitric acid, air, and steam are passed into large leaden chambers. The sulphur dioxide is oxidized to sulphuric acid, with formation of a lower oxide of nitrogen. This oxide acts as a medium for carrying oxygen of the air to sulphur dioxide. The probable changes taking place in the chambers are these: (1) $SO_2 + 2HNO_3 = H_2SO_4 + 2NO_2$. (2) $4NO_2 + H_2O = N_2O_3 + 2HNO_3$. (3) $SO_2 + N_2O_3 + H_2O = H_2SO_4 + 2NO$. (4) $2NO + O = NO_2$ Since the oxide of nitrogen is always set free and is available again for further work, theoretically a small quantity would be sufficient to convert an

infinitely large quantity of SO_2 into H_2SO_4. But there is always some loss, which must be made good from time to time. If the supply of steam falls short, crystals appear, the formation of which may be represented thus, $2SO_2 + N_2O_3 + O_2 + H_2O = 2SO_2 \begin{cases} OH \\ NO_2 \end{cases}$. These are known as "lead chamber crystals." In presence of sufficient steam they dissolve, forming sulphuric acid and oxide of nitrogen; thus, $2SO_2 \begin{cases} OH \\ NO_2 \end{cases} + H_2O = 2H_2SO_4 + N_2O_3$. When the acid in the chamber has reached a specific gravity of 1.55–1.60 (64 per cent.) it is drawn off and evaporated in leaden pans to the specific gravity of 1.75 (78 per cent.). It then attacks the lead, and is transferred to iron, glass, or platinum vessels, and further evaporated until it contains 93–94 per cent. of H_2SO_4. To prevent any loss of oxide of nitrogen from the exit of the chamber, the escaping gases are made to pass up a tall tower (Gay-Lussac) filled with coke or pumice stone over which concentrated sulphuric acid is allowed to trickle. The oxide is dissolved in the strong acid. To regain the oxide of nitrogen, the acid from this tower is made to trickle down a second one, called the Glover tower, into which weak sulphuric acid is also introduced from above, for the purpose of diluting the concentrated acid. Under these conditions the oxide of nitrogen escapes. The sulphur dioxide from the generating furnace is made to pass up the Glover tower and thus sweeps along the liberated oxide of nitrogen into the chambers. At the same time the high temperature of the dioxide serves to concentrate the acid by evaporating the water.

In England and on the continent, SO_2 is generated by roasting iron pyrites, chiefly from Spain; also zinc sulphide. As these are impure, the sulphuric acid usually contains arsenic and other substances. In this country Sicilian sulphur is burned, and to some extent American pyrites, which yield a much purer acid than the English acid, since the raw materials are practically free from arsenic.

Purification.—To remove arsenic, the chamber acid is treated with H_2S and the precipitated arsenous sulphide filtered off. Another method is to warm the chamber acid to 70°–80° C. (158°–176° F.) and add a quantity of sodium thiosulphate equivalent to the content of arsenic, when arsenous sulphide is precipitated; thus, $As_2O_3 + 3Na_2S_2O_3 = As_2S_3 + 3Na_2SO_4$. The acid which has been concentrated in lead pans can be purified and further concentrated by cooling, whereby crystals of the composition $H_2SO_4.H_2O$ separate. By repeating the process, a pure acid is obtained. To remove any nitrogen trioxide, the acid is heated with ammonium sulphate: $(NH_4)_2SO_4 + N_2O_3 = H_2SO_4 + 3H_2O + 2N_2$. The final purification is by distillation from glass retorts. This is a more or less dangerous operation, which can be conducted successfully best on the large scale.

Commercial Sulphuric Acid. *Acidum Sulfuricum Crudum*, P. G.—It forms a colorless or brownish, inodorous, oily liquid, intensely acid and corrosive, having a specific gravity of not less than 1.830, and containing not less than 91 per cent. of absolute H_2SO_4 (P. G.). It holds a small quantity of lead sulphate in solution, which, however, does not render it unfit for pharmaceutical purposes if it is otherwise pure, more particularly free from arsenic, since the lead salt is precipitated when the acid is diluted with water or alcohol. It is also liable to contain small quantities of nitric, hydrochloric, and sulphurous acids, iron and other metals, lime, ammonia, and other alkalies.

Sulphuric acid is manufactured by the millions of tons, the largest proportion being produced in the United States and England, each country yielding upward of a million tons annually. It is used more than any other acid and for all varieties of purposes; for example, liberating many other acids, in preparing soda from salt, in refining petroleum, in the manufacture of fertilizers, and also phosphorus and phosphoric acid, in bleaching and dyeing industries, etc.

Fuming Sulphuric Acid, Pyrosulphuric Acid, Nordhausen Oil of Vitriol. —The acid received its name from the place where it was first prepared, in Saxony. In fact, the method for making it is the oldest of all, and consists in heating anhydrous ferrous sulphate in earthenware retorts to red heat: $2FeSO_4 = Fe_2O_3 + SO_2 + SO_3$. The anhydride SO_3 is caught in a small quantity of water or sulphuric acid; SO_2 escapes as a gas, and the red oxide of iron, Fe_2O_3, remaining in the retort is sold as polisher under the name *colcothar* or *rouge*. The acid is essentially a solution of SO_3 in H_2SO_4. It is a heavy, thick, oily liquid, usually colored from organic impurities, fumes strongly

in air, and when cooled forms crystals of the composition $H_2SO_4.SO_3$ or $H_2S_2O_7$. The acid is made principally in Bohemia and England. In Bohemia the green vitriol is first roasted to oxidize it to a basic ferric sulphate before heating in retorts, since then there is no loss due to sulphur dioxide. In recent years the method has been perfected for making SO_3 by passing SO_2 and air over finely divided platinum, when combination takes place. It is now made in large quantities in the largest factory in Germany, and it seems that the method will ultimately displace the process of producing concentrated sulphuric acid from chamber acid by evaporation, since it is much more economical and gives a much stronger acid. It cannot displace the present chamber process, however, for making the less concentrated acid, as the latter is more economical for this purpose.

Fuming sulphuric acid finds application in some chemical industries but not in pharmacy.

Sulphuric Anhydride or Sulphur Trioxide.—This distils first when Nordhausen oil of vitriol is heated. At a low temperature it forms long, colorless prisms having in quantity somewhat the aspect of asbestos. It fuses at about 16° C. (68° F.) to a colorless liquid, boils at 46° C. (114.8° F.), and dissolves in all proportions of oil of vitriol. When kept at a temperature below 25° C. (87° F.) it is gradually converted into a modification which is slightly soluble in oil of vitriol, and melts slowly above 50° C. (122° F.), at the same time passing into the former kind. Both kinds attract moisture with great avidity, forming sulphuric acid, and in contact with the air give off white fumes. Its composition is SO_3. It is now made in any desired quantity by the method given under fuming sulphuric acid above.

Persulphuric Acid, $H_2S_2O_8$, is obtained in solution by passing a current of 2 ampères through sulphuric acid of 1.4 specific gravity: $2H_2SO_4 = H_2 + H_2S_2O_8$. The salts of this acid are of more importance than the acid, and are finding application in various ways as oxidizing agents.

Properties.—Pure sulphuric acid is a clear, colorless, odorless, oily, strongly corrosive and hygroscopic liquid. When an acid containing not more than 2 per cent. of water is cooled, crystals of pure H_2SO_4 form, which melt at 10.5° C. (50.9° F.). The absolute acid has a specific gravity of 1.8384 at 15° C. (59° F.) (water at 4° C. (39.2°F.) = 1). On heating the absolute acid it begins to fume at 30° C. (86° F.), sulphur trioxide escaping. This continues until 338° C. (640° F.) is reached, when a liquid of constant composition distils, containing 98.5 per cent. of H_2SO_4, specific gravity 1.842 at 15° C. (59° F.). If a dilute acid is heated, water is given off until 338° C. (640° F.) is reached, when the above acid distils over. The affinity of concentrated sulphuric acid for water is so great that organic compounds left in contact with it are charred, while the acid at the same time acquires a brown color.

Pure sulphuric acid mixes with water and alcohol in all proportions, forming transparent liquids; a white turbidity indicates lead sulphate, which becomes black with hydrogen sulphide. The acid should contain not less than 92.5 per cent. of H_2SO_4; if 1 Gm. be diluted with water to 50 Cc., then 24.34 Cc. of this solution (= 0.4868 Gm. of the acid) should require not less than 9.25 Cc. of normal alkali for neutralization, using phenolphthalein as indicator. Each Cc. of alkali represents 0.04868 Gm. of H_2SO_4, or 10 per cent. The British Pharmacopœia requires that each Gm. of acid shall neutralize 20.1 Cc. of normal alkali solution, which corresponds to 98 per cent. of H_2SO_4, equal to 80 per cent. of SO_3.

Sulphuric acid is one of the strongest of acids. It is dibasic, and forms normal and acid salts, which are generally crystallizable and soluble in water. The barium and lead sulphates are entirely insoluble in water and diluted acids; hence their soluble salts furnish the best reagents for sulphuric acid in its uncombined and combined state.

The following table, adopted by the Pharmacopœia, gives the specific gravity of sulphuric acid of different percentage strengths, both at 15° and 25° C. (59° and 77° F.):

Per cent. sulphuric acid.	Specific gravity— 25° C. / 25° C.	Specific gravity— 15° C. / 15° C.	Correction of specific gravity for 1° C.[1]	Fractional per cent.[2]	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc. normal KOH.

Note.—To find the per cent. of SO_3, multiply the per cent. of H_2SO_4 by 0.81633; to find the per cent. of SO_4, multiply the per cent. of H_2SO_4 by 0.97946 = 5.5.

To find the weight in grammes of H_2SO_4 in 100 Cc., multiply the specific gravity by the per cent. of H_2SO_4.

To find the volume per cent. of official Sulphuric Acid, multiply the "normality" by 2.891. For the volume per cent. of official diluted Sulphuric Acid, multiply the "normality" by 45.76.

[1] Add if the temperature is above, subtract if the temperature is below, 25° C.

[2] Corresponding with a difference in specific gravity of 0.0001.

Per cent. sulphuric acid.	Specific gravity— 25° C. / 25° C.	Specific gravity— 15° C. / 15° C.	Correction of specific gravity for 1° C.	Fractional per cent.	Normality 1 Cc. requires normal KOH Cc.	Per cent. = 0.01 Cc. normal KOH.

Impurities.—The most important impurities are arsenic, lead, and nitrogen oxides. Saline additions made to increase the specific gravity of weaker acids are recognized by the fixed residue left on evaporating a small quantity from a platinum dish or crucible. Sulphurous and nitrous acids rapidly decolorize potassium permanganate. Arsenic is found principally in sulphuric acid manufactured from pyrites, more rarely if made from sulphur; for this reason the sulphuric acid manufactured in the United States is often free from this contamination. The purity of sulphuric acid is determined as follows: 1 volume of acid diluted with 5 volumes of alcohol must remain clear and free from precipitate after one hour (absence of lead sulphate, or other salts). The mixture of 1 Cc. of sulphuric acid and 5 Cc. of water should not at once discharge the color of 0.1 Cc. decinormal potassium permanganate solution (absence of sulphurous or nitrous acid). 2 Cc. of the acid, upon which a layer of ferrous sulphate solution has been carefully poured, should not cause a brown or reddish color at the zone of contact (absence of *nitric* or *nitrous acid*). In sulphuric acid diluted with 20 volumes of water no precipitate should be formed by the addition of silver nitrate solution (absence of hydrochloric acid); nor should 10 Cc. of the diluted acid be colored or rendered turbid by an equal volume of fresh hydrogen sulphide test-solution after being stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals); nor after supersaturation with ammonia-water should the acid leave any fixed residue on evaporation and ignition (absence of non-volatile impurities). 5 Cc. of the acid diluted with water (1 in 10) should not respond to the modified

[1] Note that the specific gravity diminishes in acids of more than 97.5 per cent. strength as the percentage increases.

it's test for arsenic (see under ARSENI TRIOXIDUM). On carefully pouring a on of a small fragment of sodium sulphite in 2 Cc. of hydrochloric acid upon 2 f sulphuric acid, the zone of contact should not acquire a reddish color, nor should, on warming, a red compound be separated, showing the absence of selenium. These tests are nearly identical with those adopted by the German Pharmacopœia.

Acidum Sulphuricum Dilutum, U. S., Br. *Diluted sulphuric acid,* E.; *Acide sulfurique dilué,* Fr.; *Verdünnte Schwefelsäure,* G.—Take of sulphuric acid, 100 Gm.; distilled water, 825 Gm. Pour the acid gradually, with constant stirring, into the distilled water.—U. S. Mix 1333 grains of sulphuric acid 98 per cent. with sufficient distilled water until the mixture at 15.5° C. (60° F.) measures 1 Imperial pint.—Br. Mix sulphuric acid 1 part and water 5 parts.—P. G.

In place of using metric weights, 1 ounce (av. or troy) of sulphuric acid may be carefully mixed with $8\frac{1}{4}$ ounces (av. or troy) of distilled water, and when cool sufficient distilled water should be added to bring the weight of the diluted acid up to $9\frac{1}{4}$ ounces (av. or troy).

The direction of the Pharmacopœias to add *the acid to the water* must be observed in all cases, and more particularly if large quantities of acid are to be diluted. During the mixing of the two liquids, which is performed best in a porcelain dish or beaker-glass a considerable elevation of temperature takes place, causing a portion of the water to evaporate; the weight of the cooled mixture should therefore be made up to the required weight by the addition of distilled water. Filtration through paper or decantation is necessary only when pure sulphuric acid has not been used, to remove the lead sulphate, which is deposited from the commercial acid on diluting with water. It has the general properties of the strong acid, but is not of an oily consistence, and is less caustic. The diluted acid of the U. S. P. contains 10 per cent. of absolute H_2SO_4, and 4.868 Gm. of it are neutralized by 10 Cc. of normal potassium hydroxide solution. The British Pharmacopœia requires the diluted acid to contain 13.65 per cent. of H_2SO_4; 1 Gm. to be neutralized by 2.8 Cc. of normal solution of sodium hydroxide. Other authorities direct 15.6–16.3 (P. G.), 10 (Fr. Cod.), 16.66 (P. A.), and 18.8 (F. It.) per cent. of H_2SO_4. The specific gravity of the official acid is about 1.067 at 25° C. (77° F.).

Action and Uses.—As an escharotic this acid may be employed in the treatment of indolent ulcers, gangrene, warts, and venereal sores. Michel's paste, consisting of 3 parts of sulphuric acid and 1 part of finely powdered asbestos thoroughly triturated together, has been recommended for the extirpation of skin cancers. An ointment containing 10 per cent. of the acid may be used in tinea capitis. In all of the above conditions the acid is rarely used, because of its powerful action and tendency to extend and involve healthy tissue. Internally it is tonic, astringent, and refrigerant, and may be given with excellent results in serous diarrhœa resulting from a relaxed condition of the bloodvessels of the intestines. It is employed both as a prophylactic and a cure in epidemic cholera. The drug acts favorably during convalescence from prolonged fevers, by increasing the appetite and promoting digestion. It is a chemical antidote in acute lead-poisoning, and when employed for this condition, or as a prophylactic in cholera, should be given in the strength of 5 minims (0.3 Cc.) of the acid to a wineglassful of water. Sulphuric acid is recommended in the treatment of phosphaturia, and when combined with belladonna may be given with advantage in the night-sweats of phthisis, or in those resulting from any other depraved condition of the system. Weak solutions may also be employed as a lotion for this purpose.

Concentrated sulphuric acid abstracts water from the tissues so rapidly that they become carbonized. Overdoses destroy the tissues with which they come in contact, and produce a violent gastro-enteritis with severe burning pain in the mouth, œsophagus, and stomach. Collapse followed by death may occur in a few moments; or if the dose has not been sufficient to cause perforation, a lingering death may follow. Should the patient survive several days, inflammation of the parotid gland, due to occlusion of Steno's duct, may occur. Acute nephritis with hæmaturia is sometimes observed. If recovery from the acute condition takes place, the patient frequently dies later from inanition, resulting either from stricture of the œsophagus or destruction of the gastric tubules. The treatment of poisoning consists in the administration of mild alkaline drinks, demulcents, and opium for the relief of pain. Bodily temperature should be maintained and stimulation given as needed.

The dose of the pure acid is from 2 to 3 minims (0.10–0.20 Cc.), largely diluted and taken through a glass tube or quill. The mouth should afterward be rinsed with a mild alkaline solution. The dose of dilute sulphuric acid is from 10 to 30 minims (0.60–2 Cc.), largely diluted and taken through a tube (see ACIDUM SULPHURICUM AROMATICUM).

ACIDUM SULPHURICUM AROMATICUM, *U. S.*, *Br.*—Aromatic Sulphuric Acid.

Tinctura aromatica acida, Elixir vitrioli Mynsichti.—Elixir of vitriol, E.; *Elixir vitriolique, Teinture (Alcoolé) aromatique sulfurique*, Fr.; *Saure aromatische Tinktur*, G.

Preparation.—Add gradually sulphuric acid 111 Cc. to alcohol 700 Cc., and allow the mixture to cool. Then add to it tincture of ginger 50 Cc., oil of cinnamon 1 Cc., and sufficient alcohol to make the product measure 1000 Cc.—U. S.

In the absence of metric measures the following proportions will yield a preparation of official strength: Sulphuric acid (92.5 per cent.) 11 fluidrachms, tincture of ginger 5 fluidrachms, oil of cinnamon 5 drops, alcohol sufficient to make 12½ fluidounces. Aromatic sulphuric acid is a light-colored liquid, of about 0.933 specific gravity at 25° C. (77° F.), and contains, when freshly made, about 11 per cent. by volume of official sulphuric acid, or nearly 20 per cent. by weight of absolute acid. Upon standing, chemical action ensues, and a part of the sulphuric acid is gradually converted into ethylsulphuric (sulphovinic) acid, according to the equation: $H_2SO_4 + C_2H_5OH = C_2H_5HSO_4 + H_2O$. The newly formed compound is soluble in water and alcohol, but is not precipitated by barium chloride; by boiling its aqueous solution it is split up into sulphuric acid and alcohol. To determine the acid strength of aromatic sulphuric acid, 10 Gm. of the latter should be diluted with 30 Cc. of water, the mixture boiled for a few minutes, and when cool titrated with normal alkali solution, using phenolphtalein as indicator. Each Cc. of the alkali solution required corresponds to 0.04867 Gm. of absolute sulphuric acid.

The aromatic sulphuric acid of the present Pharmacopœia differs considerably from the preparation of the same name of the 1870 Pharmacopœia, formerly often prescribed under the name of Elixir of Vitriol. The latter preparation was of a brownish-red color, and very prone to precipitation; it was made by percolating 1 troyounce of ginger and 1½ troyounces of cinnamon with 1 pint of alcohol, and adding this to a previously prepared and cooled mixture of 1 pint of alcohol and 6 troyounces of sulphuric acid.

The British Pharmacopœia recognizes a preparation slightly weaker than that of the United States. It is a mixture of sulphuric acid (98 per cent.) 3 fluidounces, spirit of cinnamon ½ fluidounce, tincture of ginger 10 fluidounces, and alcohol (90 per cent.) 29½ fluidounces. It has a specific gravity of 0.922–0.926, and 100 Gm. should correspond in neutralizing power to 13.8 Gm. of absolute sulphuric acid.

Action and Uses.—This preparation is preferable to any other form of this acid. It possesses tonic and astringent properties, and is employed in all conditions for which the dilute acid is adapted. It is especially useful in the night-sweats of phthisis, other hectic conditions, and gastro-intestinal disorders attended with colliquative serous stools.

The dose is from 10 to 30 minims (0.60–2 Cc.), largely diluted, two or three times daily. The mouth should afterward be rinsed with a mild alkaline solution, to prevent injury to the teeth.

ACIDUM SULPHUROSUM, *U. S.*, *Br.*—Sulphurous Acid.

Acide sulfureux, Fr.; *Schweflige Säure*, G.

An aqueous solution of sulphurous acid containing not less than 6.4 per cent. of SO_2 (U. S.) or 5 per cent. (Br.) and having the specific gravity 1.028 (U. S.) or 1.025 (Br.).

The term sulphurous acid is commonly, though erroneously, given to SO_2, which chemically is sulphurous anhydride or sulphur dioxide. Sulphurous acid, H_2SO_3, does not exist in the free state, but undoubtedly is present in solution when SO_2 is passed into water.

History and Production.—Sulphurous acid was first distinguished from sulphuric acid by Stahl (1697); its properties in the gaseous state were studied by Priestley (1775), and Lavoisier (1777) showed that it contained less oxygen than sulphuric acid. It is met with in the exhalations of active volcanoes, and is produced on the burning of

sulphur, by roasting sulphides, and when concentrated sulphuric acid is heated with charcoal or with organic matters, with copper, mercury, or other metals. The official process is as follows:

Preparation.—Take of sulphuric acid, 60 Cc.; charcoal, in coarse powder, 20 Gm.; distilled water, 500 Cc. Pour the acid upon the charcoal previously introduced into a glass flask, and mix the two well together. By means of a glass tube and well-fitting corks connect the flask with a 200-Cc. wash-bottle, which is one-third filled with water and fitted with a rubber stopper having three perforations. Into one of these perforations insert a safety-tube, which should reach nearly to the bottom of the bottle; into the remaining perforation fit a glass tube and connect it with a bottle provided with a doubly perforated rubber stopper, having a capacity of about 1000 Cc., and containing 500 Cc. of well cooled distilled water This tube should dip about 1 inch (25 Mm.) below the surface of the water. By means of a second tube connect this bottle with another containing water, the end of the tube extending 2 inches (5 Cm.) below the surface. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask until the evolution of gas has nearly ceased, and during the passage of the gas keep the bottle containing the distilled water at or below 10° C. (50° F.) by surrounding it with cold water or ice. Assay a small portion of the sulphurous acid by the method given below. Then add to the remainder sufficient distilled water to bring the product to the strength of 6.4 per cent. of sulphurous acid gas. Finally, pour the sulphurous acid into dark amber-colored, glass-stoppered bottles, which should be completely filled, and kept in a cool place, protected from light. Owing to its rapid deterioration, sulphurous acid should be frequently assayed, and none should be dispensed if it fails to conform to the assay given below.—U. S. If a safety-tube be inserted in the apparatus, the delivery-tube may be allowed to reach to near the bottom of the distilled water.

The charcoal acts as a reducing agent upon the sulphuric acid, generating carbon dioxide and sulphurous anhydride and water; thus, $C + 2H_2SO_4 = CO_2 + 2SO_2 + 2H_2O$. The gas is therefore contaminated with carbon dioxide, which will likewise be retained by the distilled water to a slight extent. A purer acid is obtained by heating copper clippings with concentrated sulphuric acid, when copper sulphate and sulphur dioxide will be produced: $Cu + 2H_2SO_4 = CuSO_2 + SO_2 + 2H_2O$. Double the quantity of sulphuric acid will be necessary to produce the same amount of sulphurous acid as is produced by the official process.

Properties and Tests.—Sulphur dioxide is a colorless, irrespirable, pungent, and suffocating gas, and condenses to a liquid at —10° C. (14° F.) or under a pressure of 4 or 5 atmospheres, which boils at —8° C. (17.6° F.) and solidifies at —76° C. (—104.8° F.); this liquid boils briskly on coming into contact with ice.

The density of sulphur dioxide gas is 2.211. 1 volume of water dissolves

	At 0°. C. (32° F.).	At 15° C. (59° F.).	At 20° C. (68° F.).	At 40° C. (104° F.)
Volumes of SO_2	80	43.5	39.4	18.8

The solution contains sulphurous acid, $H_2SO_3 = (HSO_2(OH))$, and when saturated at ordinary temperature has, according to Anthon (1860), the density 1.046 and contains 9.54 per cent. of SO_2. 1 volume of alcohol at 15° C. (59° F.) dissolves 115.8 volumes of SO_2; camphor and glacial acetic acid dissolve 308 and 318 volumes of SO_2, respectively.

The aqueous solution of sulphurous acid in contact with air is oxidized to sulphuric acid, and when exposed to light it acquires the property of precipitating silver sulphide from silver nitrate. The gas remains with the water when the solution freezes, and at the boiling temperature some time elapses before it is entirely expelled.

Sulphurous acid is a powerful deoxidizing agent, abstracting oxygen from permanganic, chromic, iodic, arsenic, nitric, and other acids, from ferric, mercuric, argentic, and other salts, and from most vegetable colors, thereby bleaching the latter. It yields hydrogen sulphide and water when in contact with nascent hydrogen. It displaces carbon dioxide from carbonates, and yields salts which generally are sparingly soluble in water, except the alkali sulphites; they are inodorous, have a somewhat acrid taste, and on ignition are converted into sulphate and sulphide, or sulphur dioxide is given off, the metallic oxide remaining.

Official sulphurous acid is a colorless liquid, having the characteristic odor of burning

sulphur and an acid sulphurous taste. Its specific gravity is not less than 1.028 at 25° C. (77° F.), U. S., 1.025 at 15.5° C. (60° F.), Br., and when evaporated it leaves no residue. Blue litmus-paper moistened with the acid is first reddened and afterward bleached. On gently heating a few Cc. of the acid in a test-tube, the gas evolved will blacken a strip of paper moistened with mercurous nitrate test-solution, but will not affect one moistened with lead acetate test-solution. On mixing in a test-tube 1 Cc. of sulphurous acid with 5 Cc. of diluted hydrochloric acid, and adding a small piece of pure zinc, hydrogen sulphide gas will be evolved, which will blacken a strip of paper moistened with lead acetate test-solution.—U. S. It gives but a slight precipitate with solution of barium chloride (absence of sulphates), but a copious precipitate if solution of chlorine also be added (Br.). If to 10 Cc. of sulphurous acid there be added 1 Cc. of diluted hydrochloric acid and afterward 1 Cc. of barium chloride test-solution, not more than a slight turbidity should be at once produced (limit of sulphuric acid).—U. S. Mixed with 100 times its volume of recently boiled and cooled water and a little mucilage of starch it should not acquire a permanent blue color with volumetric solution of iodine until, for each gramme of the acid, 15.7 Cc. of the iodine solution have been added.—Br.

Assay of Sulphurous Acid.—Dilute 10 Gm. of the sulphurous acid to be assayed with enough distilled water to measure 100 Cc. To 15.9 (15.898) Cc. of this solution add 35 Cc. of tenth-normal iodine solution, and allow it to stand for 5 minutes, then add tenth-normal sodium thiosulphate solution until it is just decolorized. Subtract the number of Cc. of tenth-normal sodium thiosulphate solution used from the number of Cc. of tenth-normal iodine solution taken, and multiply the remainder by 0.2, which will give the percentage of sulphurous acid gas in the liquid, each Cc. of the tenth-normal iodine solution consumed corresponding to 0.2 per cent. of sulphur dioxide. Dilute the sulphurous acid with distilled water, as directed in the process above, so that it shall have the strength of 6.4 per cent. of sulphurous acid gas. Finally, test the finished product, when 15.9 (15.898) Cc. of the acid, diluted as above, should, after adding 35 Cc. of tenth-normal iodine solution, and allowing it to stand for 5 minutes, require not more than 5.3 Cc. of tenth-normal sodium thiosulphate solution for decolorization. —U. S.

Practical Uses.—Sulphurous acid is employed in the preparation of sodium, calcium, and other sulphites, and of calomel by the wet process, and serves as a powerful reducing agent. In pharmacy and the arts it is used for bleaching sponges, bones, straw, and other organic matters, for removing fruit-stains, and for arresting or preventing fermentation and putrefaction. Liquid SO_2 is sold in iron containers.

Action and Uses.—Sulphurous acid possesses germicidal and disinfectant properties. It arrests fermentation and putrefaction by destroying the germs which produce them. The fumes of burning sulphur, which contain large quantities of the acid, have been largely replaced by formaldehyde for disinfecting purposes, as the latter is more powerful and does not possess the bleaching property of the former. In the strength of 1 per cent. by volume it destroys most micro-organisms, but does not kill the spores.

The drug is rarely employed in medicine, but may be used with advantage in the treatment of parasitic skin diseases. Inhalations have been recommended for whooping-cough, and a solution of the acid is considered valuable in gangrenous pharyngitis as a gargle. Internally it may be employed in the treatment of urticaria and flatulent dyspepsia.

The dose is stated to be from ½ to 2 drachms (2–8 Cc.), largely diluted.

ACIDUM TANNICUM, *U. S., Br., P. G.*—Tannic Acid.

Acidum gallotannicum, Tanninum.—Gallotannic acid, Digallic acid, Tannin, E.; *Acide tannique, Tannin*, Fr.; *Gerbsäure, Gallusgerbsäure, Tannin*, G.; *Acido tannico*, It., Sp.

Formula, $C_{14}H_{10}O_9 = (C_6H_2)_2.(OH)_3.OCO.COOH$. Molecular weight, 319.66.

Origin and Varieties.—The generic name tannin is employed to designate compounds widely diffused in the vegetable kingdom, which are characterized by an astringent taste and the property of precipitating gelatin and albumin from their solutions, and also of producing dark-colored solutions or precipitates with salts of iron. The tannin or tannic acid employed in medicine is more specifically known as gallotannic acid, from its source, nutgall, and was first obtained by Deyeux and Seguin toward the close of the eighteenth century; it has also been met with in the leaves of tea and

sumach. Trimble divided all tannins into two main groups, designated as the gallo-tannic-acid group and the oak-tannin group. To the first group belong, besides nutgall tannin, the tannins found in chestnut wood, chestnut bark, pomegranate bark, and sumach; while the second comprises the tannins of the different species of oak, of kino, catechu, krameria, tormentil, mangrove, and canaigre. They are distinguished from each other by their behavior toward lime water, bromine water, and ferric salts, as explained below.

Preparation.—Two methods are extensively employed at the present time for the manufacture of tannic acid on a commercial scale.

1. Moderately finely powdered galls are treated with water heated to 40° or 60° C. (104°–140° F.) until the powder is exhausted and a concentrated solution obtained; this is allowed to settle, and is then filtered into a churn-like vessel provided with numerous paddles. To the liquor is now added about ¼ of its volume of ether (specific gravity 0.750), and the mixture thoroughly agitated; when the resulting emulsion is allowed to stand for several days it separates into two distinct layers, the upper ethereal layer being a solution of resin, fat, gallic acid, and coloring-matter, while the lower aqueous layer contains the tannin with some few impurities. After separation the tannin solution is concentrated, under reduced pressure, in a still to a syrupy consistence, and then spread on plates of sheet tin, which are warmed, so that the tannin may be obtained as dry, spongy masses; the syrupy liquid may also be spread on glass plates, which are then heated in drying ovens to 110° C. (230° F.).

2. Nutgall in moderately fine powder is exhausted in stoneware or glass vessels with a mixture of 4 parts of ether and 1 part of 90 per cent. alcohol by repeated maceration with fresh portions of solvent. The united liquids are repeatedly shaken with water, which takes up the tannic acid, and having been treated, if necessary, with animal charcoal, the aqueous solution is concentrated and further treated as above stated.

Two other varieties, less pure, are met with, known as alcohol-tannin and water-tannin; the former is made by extracting nutgall with 50 per cent. alcohol, carefully filtering, and concentrating the solution, which is finally evaporated in a vacuum. Water-tannin is extracted similarly to ether-tannin, but, instead of adding ether, the solution, after filtration, is concentrated to dryness in a vacuum apparatus. Pure tannic acid has been obtained by Gartenmeister by exhausting powdered galls with acetic ether, and a patent has been granted for the process in Germany. The acetic ether solution is concentrated, and thoroughly agitated with water, which forms an emulsion, from which the impurities are removed by centrifugal action and admixture of charcoal or pumice-stone. Finally, the aqueous solution, almost free from color, is evaporated to dryness by appropriate means. It is scarcely necessary to state that in all these methods contact with metal, especially iron, must be avoided to prevent discoloration of the final product. The so-called crystallized tannic acid is simply finely spun tannin obtained in thin threads by forcing a concentrated solution through finely perforated sieves, and allowing the mass to fall from a height of 15 feet or more on to rapidly revolving wood cylinders.

Properties.—Tannic acid has a yellowish-white color, frequently of a slight greenish tint. It is odorless or has a faint characteristic odor, a strongly astringent taste, and is soluble in about 0.336 part of water or 0.224 part of alcohol at 25° C. (77° F.). Very soluble in boiling water, boiling alcohol, and in diluted alcohol, also in 1 part of glycerin moderately heated; but remains pulverulent when in contact with anhydrous ether which is free from alcohol, and is likewise insoluble, or nearly so, in absolute alcohol, chloroform, petroleum benzin, benzene, carbon disulphide, and in most fixed and volatile oils. The solutions have an acid reaction. Tannic acid being less soluble in acidulated water and in solutions of certain salts than in pure water, its aqueous solution is precipitated by mineral and certain organic acids, by the chlorides and several other salts of the alkalies, these precipitates being again soluble in water. Tannin renders iodine soluble in water, and prevents the reaction of the latter upon starch; this behavior has been recommended by F. Jean for the estimation of tannin. It yields precipitates with the alkaloids and many so-called neutral principles, with lime water, most metallic salts, with starch, albumin, and gelatin. The latter precipitate is soluble in solutions of gelatin and of tannin, but insoluble in water and aqueous solutions of certain salts (see Gelatina); this tannate of gelatin is formed in the tanning of hides, and is an important constituent of leather. With solutions of pure ferrous salts no change takes place in the absence of oxygen, but ferric salts give at once in diluted solutions a deep-blue color, and in more concen-

trated solutions a bluish-black precipitate, with a reduction to ferrous compounds. In the presence of alkalies and in contact with air solutions of tannin rapidly assume a brown color.

Composition.—The impossibility of obtaining tannic acid in the crystallized state has rendered the determination of its composition difficult. It has been the subject of frequent investigations, and not until Schiff (1871) and Etti (1884) announced the result of their work was the true chemical character of tannic acid understood. Owing to the fact that it is generally contaminated with variable proportions of glucose in weak combination, the view that tannic acid is a glucoside prevailed for a long time. From this it can be completely freed, however, as suggested by Trimble, by treatment with lead acetate and hydrogen sulphide and subsequent extraction with acetic ether. Tannic acid, when pure, is now looked upon as digallic acid or an anhydride of gallic acid. This relation is seen from the following equation: $2(C_6H_2(OH)_3.COOH)$ (gallic acid) $- H_2O = (C_6H_2)_2.(OH)_5.OCO.COOH$ (tannic acid) $= C_{14}H_{10}O_9$.

Tests.—Tannic acid should burn from platinum-foil without leaving more than 0.2 per cent. of ash, and be completely soluble in 5 parts of alcohol (dextrin insoluble) and the same proportion of warm water (resin insoluble), both solutions being nearly transparent. The latter solution should not be precipitated on mixing it with twice its volume of alcohol.

If a small quantity of lime water be added to a 1 per cent. aqueous solution of tannic acid, a pale bluish-white precipitate is produced, which is not dissolved on shaking (difference from gallic acid), and which deepens in color and increases by addition of a moderate excess of lime water; a large excess of lime water gives to the solution a pale pinkish tint.

The following reactions serve to distinguish between the members of the gallotannic acid group and those of the oak-tannin group: Gallotannic acid causes a blue precipitate with lime water, while with oak-tannins a pink or red precipitate is obtained. It is not affected by bromine water, whereas oak-tannins produce a yellow precipitate. Ferric chloride and ammonium hydroxide cause a green precipitate with oak-tannins and a blue precipitate with gallotannic acid; the blue color sometimes observed in the case of oak-tannins with ferric salts is due to the presence of a foreign substance, and is never caused by the pure article (Trimble).

Estimation.—The estimation of tannin and the valuation of the various tanning materials are conducted with considerable difficulty, and often require to be modified according to the nature of other organic compounds present.

Von Schröder's modification of Löwenthal's method, although by no means free from defect, is looked upon as the most reliable for technical analysis; it was adopted by a committee of German chemists in 1885. The method combines Hammer's suggestion for the use of hide-powder with Löwenthal's for potassium permanganate in presence of indigo; the value of the permanganate solution for a known quantity of pure tannin before and after treatment with hide-powder must first be established, solution of sodium sulphindigotate being used as indicator; it is assumed that when the color of the indigo solution changes to a pure golden-yellow (evidence of complete oxidation) all the tannin present will also have been oxidized by the permanganate. The necessary reagents are (1) a solution of pure potassium permanganate of the strength of 10 Gm. to 6000 Cc. of distilled water; (2) a solution of 30 Gm. of pure sodium sulphindigotate in 3000 Cc. of dilute sulphuric acid (1 volume of acid, 5 volumes of water)—after filtration 3000 Cc. more of water are added; (3) white woolly hide-powder, which yields to distilled water nothing capable of reducing the permanganate solution; (4) strictly pure tannin. The indigo solution should be tested separately, and 20 Cc. of the same, when diluted with 750 Cc. of water, should require about 10.7 Cc. of the permanganate solution for oxidation.

To standardize the tannin value of the permanganate solution, 10 Cc. of a solution of pure tannin (2 Gm. to 1000 Cc.) are added to 20 Cc. of indigo solution and 750 Cc. of water; the $KMnO_4$ solution is cautiously added until the color changes to pure yellow. 50 Cc. of tannin solution are now macerated with 3 Gm. of hide-powder, previously well moistened and expressed, for 18 or 20 hours with frequent agitation, filtered, and 10 Cc. of the filtrate added to 20 Cc. of indigo solution and 750 Cc. of water; the mixture is titrated with $KMnO_4$ solution as before, the difference between the first and second titrations representing the tannin or oxidizable matter removed by the hide. From these data the tannin value per Cc. of permanganate solution is readily calculated. For subsequent estimation of tannin in infusions or otherwise, the same reagents must be employed, and

the liquid to be tested should contain a quantity of tannic acid corresponding to not less than 4 nor more than 10 Cc. of permanganate solution.

Pharmaceutical Preparations.—Glycerite of Tannic Acid, Styptic Collodion, Troches of Tannic Acid, Ointment of Tannic Acid, U. S. P.

Action and Uses.—Tannic acid possesses considerable astringent and slight irritating properties. When locally applied to the tissues, it constricts the bloodvessels present and temporarily decreases the vascularity of the part. Taken internally, it lessens secretion and produces constipation. If mixed with blood or injected into the circulation, it causes coagulation of the albumin, thus forming a clot. Tannic acid is rapidly absorbed as gallic acid. It is mostly oxidized in the body, but portions of it are eliminated by the kidneys as gallic acid.

Tannic acid acts as such only before it is absorbed, and can be employed only in those conditions which permit of its direct application. It has been used largely to control hemorrhages; as, for example, epistaxis, the various forms of uterine hemorrhage, hæmatemesis, and, in the form of a spray, in hæmoptysis. It may be employed as an astringent to relaxed mucous membranes, and, as such, is of use in the treatment of serous diarrhœa. Solutions of tannic acid are useful in the treatment of aphthous stomatitis, spongy gums, ptyalism, and chronic pharyngitis with relaxation of the uvula. Vaginal leucorrhœa has been cured by the application of a saturated solution upon cotton, and bleeding hemorrhoids are frequently benefited by the insertion of a suppository containing 2 to 5 grains (0.10–0.30 Gm.) of the acid. Its application in the treatment of chronic inflammation of the conjunctiva, especially pannus, is also attended with good results.

Internally the dose of tannic acid is from 3 to 10 grains (0.20–0.60 Gm.), repeated as often as is deemed essential. For local application, a solution containing from 3 to 10 grains (0.20–0.60 Gm.) of the acid in 1 fluidounce (30 Cc.) of water may be employed. Should a more powerful solution be desired, the glycerite may be used (see Glyceritum Acidi Tannici).

Derivatives.—Tannalbinum.—*Tannalbin.*—A compound of tannin and albumin, obtained by mixing 10 parts of a 10 per cent. solution of egg-albumin with 6.5 parts of a 10 per cent. solution of tannin in water, collecting the resulting precipitate, and washing the same with water until the filtrate scarcely reacts with ferric chloride. After drying on porous tiles it is powdered and heated for 6 hours to 120° C. (248° F.). It occurs as a brownish, odorless, and tasteless powder, containing about 50 per cent. of tannin, and is sparingly soluble in water and alcohol. Tannalbin is employed internally in cases of serous diarrhœa as an astringent. It is not dissolved by the gastric juices, but is decomposed by the alkaline secretions of the intestines, and its dose is from ½ to 2 drachms (2–8 Gm.).

Tannigenum.—*Tannigen, Diacetyl-tannin.* $C_{14}H_8(CH_3CO)_2O_9$.—An odorless and tasteless compound, obtained by heating tannic acid with acetic anhydride and glacial acetic acid in a flask provided with a reflux condenser. The resulting product is added to water, and the precipitate which is formed is then washed with warm water, dried, and powdered. It occurs as a yellowish-gray powder, insoluble in water and dilute acids, but readily soluble in alcohol and in alkaline solutions, such as sodium phosphate, sodium carbonate, and borax. Tannigen has been highly recommended by some practitioners in the treatment of chronic diarrhœa, as it is an intestinal astringent, and which because of its insolubility escapes through the stomach into the intestines, where the alkaline secretions of the small intestine break it up into its constituent parts. Its dose is 4 to 8 grains (0.2–0.5 Gm.).

Tannoformum.—*Tannoform, Methylene-ditannin.* $CH_2(C_{14}H_9O_9)_2$.—A condensation-product of tannin and formaldehyde, prepared by mixing a solution of 5 parts of tannin in 15 parts of hot water with 3 parts of a 30 per cent. solution of formaldehyde, and then adding strong hydrochloric acid as long as precipitation continues. The precipitate is washed with water and dried with moderate heat. It is a pale-reddish light powder, without odor or taste, insoluble in water, but soluble in alcohol and in alkaline liquids. Tannoform has been used locally as a dusting-powder for burns and excessive sweating, and as an astringent agent in ozæna, pruritus, and hemorrhoids. Internally it is given in chronic intestinal catarrh. When used as a dusting-powder, it should be mixed with from 2 to 4 parts of starch. Internally its dose is from 4 to 8 grains (0.25–0.5 Gm.).

ACIDUM TARTARICUM, *U. S., Br., P. G.*—Tartaric Acid.

Dextrotartaric acid, Di(hydr)oxy succinic acid, E.; *Acide tartrique, Acide dextero racémique, Acide du tartre,* Fr.; *Weinsäure, Weinsteinsäure,* G.; *Acido tartarico,* It., Sp.

Formula, $H_2C_4H_4O_6$ or $[CH(OH)]_2(COOH)_2$. Molecular weight, 148.92.

History.—Dextrotartaric acid was isolated first by Scheele in 1768, and obtained in

the crystalline form by Retzius in 1770, who designated it *Sal essentiale tartari*. Its composition and salts were studied by Gay-Lussac, Berzelius, and others; its optical properties especially by Biot (1815) and Pasteur (1841).

Occurrence.—Dextrotartaric acid, commonly designated merely as tartaric acid, is one of the most widely distributed vegetable acids. It occurs partly free, partly combined with potassium and calcium in numerous fruits (grapes, tamarinds, mountain ash berries); occasionally also in roots, leaves, and flowers.

Formation and Preparation.—It results upon the oxidation with nitric acid of starch, gum, cane-sugar, milk-sugar, grape-sugar, sorbin, saccharic acid, and other substances.

It is prepared from crude tartar, which consists principally of acid potassium tartrate and some calcium, magnesium, iron, and aluminum salts. The salts are dissolved in water at 140°–170° C. (284°–338° F.) under pressure and the clear solution rendered almost neutral by addition of chalk: $2KHC_4H_4O_6 + CaCO_3 = CaC_4H_4O_6 + K_2C_4H_4O_6 + CO_2 + H_2O$. Complete neutralization should be avoided in order to retain in solution the magnesium, iron, and aluminum salts. In order to convert the normal potassium tartrate resulting according to the above equation and remaining in solution, into insoluble calcium tartrate, calcium chloride is added to the hot mixture: $K_2C_4H_4O_6 + CaCl_2 = CaC_4H_4O_6 + 2KCl$. The normal calcium tartrate resulting in accordance with both equations is sparingly soluble even in hot water. After being washed well with water it is decomposed with little more than the theoretic amount of dilute sulphuric acid at a temperature of 70°–75° C. (158°–167° F.). The solution of the free acid is evaporated in lead vacuum pans and the concentrated liquid allowed to crystallize in lead-lined vats. The resulting acid is redissolved, decolorized by means of animal charcoal, and recrystallized. In order to obtain well-developed, transparent crystals for the arts, tartaric acid is recrystallized from a solution to which some sulphuric acid has been added.

Properties.—Tartaric acid occurs in colorless translucent monoclinic prisms, or crystalline crusts, or a white powder, odorless, having a strongly acid, not disagreeable, taste, and permanent in the air. It is soluble at 25° C. (77° F.) in about 0.71 part of water and in 1.67 parts of alcohol, in about 0.5 part of boiling water, and in about 0.2 part of boiling alcohol; also in 250 parts of ether (50 parts, P. G.); nearly insoluble in chloroform, benzene, or benzin. When heated for some time at 100° C. (212° F.) the powdered crystals do not suffer a sensible loss of weight. At 135° C. (275° F.) the acid melts, and above 180° C. (356° F.) it is gradually decomposed into pyrouvic, pyrotartaric, and pyrotartrillic acids, carbon dioxide, etc., and emits the odor of burning sugar; it is finally consumed without leaving more than 0.05 per cent. of ash. Tartaric acid has an acid reaction upon litmus-paper. If an aqueous solution (1 : 2) of the acid be mixed with a strong solution (1 : 3) of potassium acetate, a white crystalline precipitate of potassium acid tartrate will be formed, which is insoluble in acetic acid, but soluble in mineral acids and solutions of the alkalies.—U. S.

Tartaric acid is a strong dibasic acid, forming normal and acid salts, most of which are readily obtained in crystals; all are blackened by heat and evolve an odor similar to that of burning sugar.

Tests.—The absence of sulphuric acid, as required by the Pharmacopœia, may be shown by adding to a 10 per cent. solution of tartaric acid a few drops of hydrochloric acid and then some barium chloride test-solution; the liquid should remain clear. Calcium sulphate test-solution should not cause a precipitate in a 10 per cent solution of the acid nearly, but not entirely, neutralized by addition of ammonia water, showing the absence of oxalic and uvic acids, which would form insoluble calcium salts. Neither ammonium oxalate nor hydrogen sulphide test-solutions should affect a solution of the acid supersaturated with ammonia, thus showing the absence of calcium salts and of heavy metals, as iron, lead, copper, etc. The Pharmacopœia requires that 3.73 Gm. of tartaric acid shall require not less than 49.75 Cc. of normal potassium hydroxide solution for neutralization, using phenolphthalein as indicator, thus demanding not less than 99.5 per cent. of purity.

Action and Uses.—Tartaric acid is rarely prescribed alone, but is given in combination with alkalies or alkaline carbonates. It is frequently employed in place of citric acid and lemon-juice in the preparation of acidulous drinks and effervescing draughts. In its action it resembles citric acid, but is more irritating, and poisonous amounts cause

gastro-enteritis, great pain, collapse, and death. The drug is usually given in the dose of from 10 to 30 grains (0.60–2 Gm.), dissolved in water and sweetened to suit the taste. If a small amount of spirit of lemon be added to this solution, it may be used as a substitute for lemonade.

ACIDUM TRICHLORACETICUM, *U. S.*, *P. G.*—Trichloracetic Acid.

Acide trichloracétique, Fr.; *Trichloressigsäure*, G.

Formula, $HC_2Cl_3O_2$ or CCl_3COOH. Molecular weight, 162.12.

Preparation.—Trichloracetic acid was first prepared by Dumas by the action of chlorine on acetic acid under the influence of sunlight, mono- ($CH_2ClCOOH$) and dichlor-acetic acid ($CHCl_2COOH$) resulting as intermediate products, the former being solid and the latter a liquid compound. It is more readily prepared from chloral, CCl_3CHO, by oxidation with nitric acid, as follows: To 165.5 Gm. of chloral hydrate, previously fused at 58° C. (136.4° F.) are added 63 Gm. of fuming nitric acid and the mixture set aside for an hour or until red vapors cease to be formed. It is then carefully distilled, that portion coming over above 190° C. (374° F.), and consisting of pure trichloracetic acid, being collected separately.

Properties.—Colorless rhombic crystals, which readily deliquesce, possessing a weak pungent odor and a strongly acid reaction, soluble in water, alcohol, and ether. The aqueous solution on boiling is decomposed with the formation of chloroform and carbon dioxide. It melts at about 52° C. (125.6° F.), U. S., 55° C. (131° F.), P. G., and boils at 195 C. (383° F.), being completely volatilized; monochloracetic acid, which is also crystalline, melts at 62.5° C. (144.5° F.). If heated with potassium hydroxide solution, the crystals develop a decided odor of chloroform, due to the following reaction: $CCl_3COOH + 2KOH = CHCl_3 + K_2CO_3 + H_2O$. Sodium and potassium carbonate will likewise break down trichloracetic acid into chloroform and carbon dioxide. If 10 Gm. of trichloracetic acid be liquefied by the addition of 1 Gm. of water, a permanently fluid mixture results.

Tests.—If to 10 Cc. of a 10 per cent. aqueous solution of trichloracetic acid be added 2 drops of tenth-normal silver nitrate solution, the liquid should not become more than faintly opalescent (limit of chlorine in such combination as to be capable of reacting with the silver salt); the chlorine of trichloracetic acid behaves like the chlorine of chloroform and does not precipitate silver nitrate solution. If to its aqueous solution (1 in 10) ferric chloride test-solution be added, a faint reddish color is developed. 1 Gm. when diluted with 50 Cc. of water should not require less than 6.1 Cc. of normal sodium hydroxide solution (1 Gm. acid, when dried, not more than 6.1 Cc., P. G.) for neutralization, using phenolphthalein as indicator.—U. S.

Action and Uses.—Trichloracetic acid is an excellent cauterizing agent, as it causes very little pain and only slight inflammation. Its application is said to prevent putrefactive changes and promote rapid healing. When applied, it produces a smooth, dry, white scurf, which falls off in a few days. This acid has been quite largely employed in dental practice for the removal of small vegetations from the buccal cavity. It is claimed that it will destroy papillomata and vascular nævi. Trichloracetic acid is highly recommended in ozæna and chronic nasal catarrh associated with hypertrophy of the mucous membrane or polypoid degeneration. A solution of 1 part in 1000 of water sometimes does good in acute coryza, pharyngitis, and chronic tonsillitis. Chronic gleet may occasionally be cured by the local application of a solution containing 1 part of the acid in 20 parts of water; a 25 per cent. solution has also been used successfully in treating nasal tuberculosis. M. L. Hensner recommends the following formula: Balsam of Peru, 15 grains (1 Gm.); formic acid and chloral, each, 75 grains (5 Gm.); and 1 ounce of alcohol (30 Cc.), in the treatment of refractory localized forms of bromidrosis. This acid is not employed in internal medicine.

ACIDUM VALERIANICUM.—Valerianic Acid.

Acidum valericum.—Acide valérianique, Acide valérique, Fr.; *Baldriansäure, Valeriansäure,* G.; *Acido valerianico,* It., Sp.

Formula, $HC_5H_9O_2 = (CH_3)_2.CH.CH_2.COOH$. Molecular weight, 101.31.

Origin and Formation.—Valerianic acid has received its name from valerian root, from which it was obtained and recognized as a distinct acid by Grote (1830); it has been found in the flowers of *Anthemis nobilis,* in wormwood, angelica root, etc., and in dolphin oil, obtained from *Delphinus globiceps* Cuvier, by Chevreul (1817), who named it *delphinic acid;* it is found among the products of oxidation of a large number of organic substances, and is prepared for medicinal purposes almost exclusively by oxidizing amyl alcohol with potassium dichromate and sulphuric acid, a process recommended by Balard (1845).

Preparation.—Valerianic acid may be prepared either from valerian root or from amyl alcohol. Both kinds are offered on the market. The acid made from the root is specified in the French Pharmacopœia, the directions for which are as follows: Dissolve 600 Gm. of potassium dichromate in 10 liters of water and add 1000 Gm. of concentrated sulphuric acid, 10,000 Gm. of crushed valerian root are digested for 24 hours with this chromic acid mixture and 40 liters of water. Then distil until about 12 liters of liquid (containing essential oil) have passed over, return the distillate to the still, and again distil until the distillate no longer shows an acid reaction. Saturate the distilled liquid with sodium carbonate, reduce the solution by evaporation to a syrupy consistence, add slowly a slight excess of sulphuric acid, and allow to stand in a cylinder. The valerianic acid will collect at the surface, forming an oily layer. Decant, and rectify by distillation from a glass retort.

Valerianic acid from amyl alcohol is prepared by gradually adding 5 parts of fermentation amyl alcohol, boiling at 130° C. (266° F.), to a mixture of 5 parts of powdered potassium dichromate and 4 parts each of concentrated sulphuric acid and water. When the violent reaction has subsided, the mixture is distilled until the contents of the flask have assumed a uniform dark-green color. The oxidation of the amyl alcohol occurs as follows: $3C_5H_{11}OH + 2K_2Cr_2O_7 + 8H_2SO_4 = 3HC_5H_9O_2 + 2K_2SO_4 + 2Cr_2(SO_4)_3 + 11H_2O$. After neutralizing the distillate with caustic soda, it is evaporated to dryness and the resulting sodium valerianate is decomposed with sulphuric acid, the liberated valerianic acid being rectified by distillation. Since a small quantity of amyl alcohol escapes oxidation in the above process, it is attacked by the newly formed acid and passes over into the distillate as valerianic acid amyl ester, $C_5H_{11}C_5H_9O_2$. The name apple oil has been given to this compound on account of its apple-like odor when diluted. It separates as an oily layer on the solution of sodium valerianate, and may then be removed.

Properties.—Valerianic acid is a colorless thin oily liquid, with a disagreeable odor resembling that of valerian and of old cheese, and has a sour, acrid, unpleasant taste, producing upon the lips and tongue the sensation of burning; diluted with water, the taste is less disagreeable, with a sweet after-taste. When heated, valerianic acid evaporates without residue, and ignited burns with a luminous flame. It is soluble at 15° C. (59° F.) in 30 parts of water, and by agitation with a small quantity of that liquid takes up about 20 per cent. of its weight, without losing its oily consistence. It dissolves in all proportions in alcohol, ether, chloroform, carbon disulphide, and volatile oils, the hydrated acid, however, producing a turbid mixture with the last-named liquids. The specific gravity is 0.935, which increases if the acid becomes more hydrated; its boiling-point is 175° C. (347° F.). Musgiller ascertained that an acid of 0.933 specific gravity boils between 177.2° and 178.9° C. (351° and 354° F.); if of greater density, the boiling-point is lower.

The *normal salts* of valerianic acid, when perfectly dry, are inodorous; in the presence of moisture, and still more in contact with carbonic acid, they have the odor of valerianic acid; their taste is decidedly sweet. Most of the salts are soluble in water, several dissolve also in alcohol; from these solutions valerianic acid is liberated by nearly all the mineral and organic acids, even by acetic acid.

Tests.—The solubility of valerianic acid, in not less than 26 and not more than 30 times its weight of water, affords a ready means of discovering the presence of certain impurities. Alcohol decreases, and water, acetic acid, and butyric acid increase the

density of valerianic acid, and render it more soluble in water, while it becomes less soluble and of less density through the presence of amyl alcohol, amyl aldehyde, amyl valerianate, and fixed oils. On adding ammonia water slightly in excess to valerianic acid, a clear solution should be produced; this is turbid or separates an oily layer in the presence of one or more of the four compounds last mentioned. Butyric acid, if present, will, according to Laroque and Huraut, produce with concentrated solution of acetate of copper pale-blue scales of copper butyrate, while pure valerianic acid mixed with the same solution yields a mixture which is transparent for several minutes, then separates oily drops of copper valerianate, which are gradually converted into a greenish-blue crystalline powder. Acetic acid is readily detected by neutralizing the acid with ammonia and adding to the cold clear liquid a slight excess of diluted ferric chloride or subsulphate, when ferric valerianate will be precipitated and ferric acetate form a deep brown-red solution. Admixtures of hydrochloric or sulphuric acid are detected in the aqueous solution of valerianic acid, after adding a little nitric acid, by the nitrates of silver and barium.

Action and Uses.—Valerianic acid is employed in medicine only in combination. Ammonium valerianate is used in various nervous and hysterical manifestations, but the benefit gained by its administration is attributed principally to its disagreeable odor. Large amounts of the acid weaken the heart and increase the rapidity of its action; the respiration becomes hurried, and general weakness, paralysis of the extremities, or convulsions ensue. The mucous membrane of the gastro-intestinal tract and of the kidneys is congested, and the urine is turbid and bloody.

ACONITINA, *U. S.*, *Br.*—Aconitine.

Aconitia, E.; *Aconitine* Fr.; *Aconitin*, G.; *Aconitina*, It., Sp.

Formula, $C_{34}H_{47}NO_{11}$ (U. S.); $C_{33}H_{45}NO_{12}$ (Br.). Molecular weight, 640.55 or 642.52.

History.—The name aconitine was first applied by Geiger and Hesse in 1833 to an amorphous base obtained from the root of *Aconitum Napellus*. Since that time much work has been done with the view of obtaining the alkaloid in crystalline form and determining its true composition. Duquesnel in 1871 and Wright and Luff in 1878 succeeded in preparing crystalline aconitine, the last-named investigators proposing the formula $C_{33}H_{43}NO_{12}$. Much controversy has existed between the different investigators, which, unfortunately, up to the present time has not been harmonized. The very thorough work of Freund and Beck in 1894 and 1895, on the constitution and derivation of aconitine, led them to assign the formula given in the U. S. P., based on 14 determinations of the crystallized alkaloid, whereas the British Pharmacopœia has adopted the formula proposed in 1891 by Dunstan and Ince, of England.

Aconitine occurs in aconite root in combination with aconitic acid, associated with picraconitine and aconine.

Preparation.—In order to guard as far as possible against any change during the process of preparation, the following method of W. Dunstan may be employed: Exhaust powdered aconite root with cold rectified fusel oil and shake the resulting tincture with diluted (1 per cent.) sulphuric acid. The acid solution is treated with chloroform to remove resin, made alkaline with sodium carbonate, and shaken out with ether. The alkaloid obtained by evaporation of the ethereal solution may be dissolved in dilute hydrochloric or hydrobromic acid, and purified by recrystallization; or the solution may be precipitated by addition of gold chloride solution, the double chloride being separated and decomposed by hydrogen sulphide; after removal of the gold the alkaloid is liberated by sodium carbonate and extracted with ether, to which solution petroleum ether is then added and the alkaloid allowed to crystallize.

The French Pharmacopœia recommends a modification of Duquesnel's process, as follows: Powdered aconite root is exhausted with alcohol containing 0.5 per cent. of tartaric acid; the alcohol is distilled and evaporated at a low temperature or *in vacuo;* the extract is diluted with an equal bulk of water, filtered from the oil and resin, agitated with ether or petroleum naphtha, whereby more resin is removed, and then precipitated by excess of potassium or sodium carbonate; the alkaline liquid retains the amorphous bases in solution, while the washed precipitate, after dissolving in ether, mixing

this solution with petroleum naphtha, and evaporating, yields crystallized aconitine, which still, however, retains a small proportion of amorphous alkaloids.

Properties.—Commercial aconitine still is found in both the amorphous and crystalline forms; only the latter should be used, since the amorphous variety is a mixture of aconitine and derivative products, chiefly picraconitine, and is from 15 to 20 times less active than the crystallized article. Pure aconitine occurs in colorless hexagonal plates or prisms of the rhombic system, which melt, according to Freund and Beck, at 197° to 198° C. (386.6°–388.4° F.), and, according to the British Pharmacopœia, between 189° and 190° C. (372.2° and 374° F.). When heated rapidly, aconitine melts at 195° C. (383° F.); when heated slowly, decomposition takes place and it melts at 182° C. (359.6° F.).—U. S. Upon ignition it is consumed without leaving a residue. It is soluble in 3200 parts of water, 22 parts of alcohol, 44 parts of ether, 5.6 parts of benzene, and 3580 parts of petroleum benzin, at 25° C. (77° F.); also very soluble in chloroform (U. S.). Aconitine gives a weak alkaline reaction, dilates the pupil like atropine, and is extremely poisonous. A mere trace of the alkaloid, 1 drop of a 0.1 per cent. solution, placed on the tongue causes a persistent tingling and pricking sensation.

Tests.—Pure aconitine is not colored by solution in concentrated sulphuric acid or nitric acid; and if a mixture with phosphoric acid be evaporated in a porcelain dish on a water-bath, at most but a faint pink color will appear, whereas the impure article is colored by sulphuric acid at first yellow, then brown, and finally reddish violet, and, if treated with phosphoric acid, as before stated, an intensely violet-colored liquid results. If rubbed with sulphuric acid containing a crystal of ammonium vanadate, an orange color is produced (U. S.). Dilute solutions of aconitine yield precipitates with test-solutions of mercuric potassium iodide, tannic acid, and gold chloride, but only concentrated solutions with test-solutions of platinic chloride, mercuric chloride, and picric acid (U. S.). On evaporating 0.01 Gm. of aconitine with 5 drops of fuming nitric acid, the resulting yellow residue, when cooled, should not yield a violet color when treated with alcoholic potassium hydroxide test-solution (difference from pseudaconitine and atropine).—U. S.

"Any soluble salt of aconitine in dilutions of 1 in 1000 produces, with a drop of potassium permanganate test-solution, a blood-red precipitate of aconitine permanganate. Aconitine containing decomposition products (amorphous aconitine) produces this precipitate only in solutions containing not less than 1 in 200. Cocaine, hydrastine, and papaverine also yield a similar precipitate, but only when in more concentrated solutions."—U. S. A dilute solution of the alkaloid, even 1 part in 4000 parts of water, faintly acidulated with acetic acid, deposits a red crystalline precipitate on the addition of a few drops of solution of potassium permanganate (Br.). This reaction, which was first pointed out by Dunstan and Carr (1896), is quite characteristic and extremely delicate.

If aconitine be boiled for several hours with water, it is split up into acetic acid and picraconitine benzoate. The latter salt may be crystallized from hot water or diluted alcohol in the form of needles, which melt at 203.5° C. (398.3° F.); if decomposed by sulphuric acid and the benzoic acid removed with ether, the base may be extracted by a further treatment with ether, after addition of alkali carbonate in excess. *Picraconitine*, $C_{32}H_{45}NO_{10}$ (Freund and Beck), $C_{31}H_{43}NO_{11}$ (Dunstan), thus obtained and dried in a vacuum, occurs as a white amorphous, very bitter, but non-poisonous, mass, which melts at 125° C. (257° F.) (Dunstan), or 150°–163° C. (302°–325.4° F.) (Freund and Beck). If heated with alcoholic solution of potassium hydroxide, it is split up into benzoic acid and *aconine*, $C_{25}H_{41}NO_9$ (Freund and Beck), $C_{24}H_{39}NO_{10}$ (Dunstan), an amorphous varnish-like base, readily soluble in water and in alcohol, less so in chloroform, and insoluble in ether. Aconine is non-poisonous, has a very bitter taste, and melts at 132° C. (239.6° F.). These successive hydrolyses lead to the constitution of aconitine as acetyl-benzoyl-aconine, $C_{25}H_{39}NO_9.CH_3CO.C_6H_5CO$.

The salts of aconitine are crystalline and readily soluble in water; the hydrobromide, hydrochloride, and nitrate are used in medicine, as also the oleate, which latter, of course, is insoluble in water. Aconitine hydrobromide melts at 164° C. (327.2° F.) and the hydrochloride at 149° C. (300.2° F.) (Br.).

Other varieties of the aconite plant produce alkaloids not identical with aconitine, but resembling the latter in some respects. The two best known of these alkaloids are

offered in commerce as pseudaconitine and japaconitine, both of which are more toxic in character than crystallized aconitine, the former about twice as strong, the latter about one-fifth stronger. *Pseudaconitine*, $C_{36}H_{49}NO_{12}$, obtained from *Aconitum ferox*, occurs in prismatic crystals containing 1 molecule of water, which if anhydrous melt at 201° C. (393.8° F.) (Dunstan and Carr), or 211° C. (411.8° F.) (Freund and Niederhofheim). It is almost insoluble in water and difficultly soluble in ether, but readily soluble in alcohol and chloroform. It has a burning taste, and is said to be twice as poisonous as crystallized aconitine. Pseudaconitine if boiled with water for several hours breaks up into acetic acid and a basic substance called picropseudaconitine, which has the same empirical formula as aconitine. If picropseudaconitine be boiled with alcoholic potassium hydroxide solution, it splits up into veratric acid (dimethylprotocatechuic acid), $C_6H_3(OCH_3)_2COOH$, and pseudaconine, $C_{21}H_{25}(OCH_3)_4(OH)_2NO_2$, an amorphous base, differing from aconine in containing 2 atoms of hydrogen and 1 of oxygen less, but, like it, containing 4 methoxy and 2 hydroxy groups, and which has been called anhydroaconine. The hydrolyses of pseudaconitine point to its constitution as acetylveratroylanhydroaconine, $C_{25}H_{37}NO_8.CH_3CO.C_6H_3(OCH_3)_2CO$.

Japaconitine, $C_{34}H_{49}NO_{11}$, was first isolated from the root of *Aconitum japonicum* by Paul and Kingzett in 1877, and investigated later on by Wright and Luff. For a long time it was considered identical with aconitine until Dunstan and Read (1900) pointed out the difference between the two alkaloids, and determined the correct composition and melting-point of the former. It occurs as prismatic needles, usually crystallizing in colorless rosettes and melting at 204.5° C. (400.1° F.). When saponified by heating its sulphate with water under pressure, japaconitine is split up into acetic acid and japbenzaconine (corresponding to picraconitine), which latter crystallizes in rhomboidal plates melting at 183° C. (361.4° F.). Upon further hydrolysis japbenzaconine yields japaconine and benzoic acid, thus showing a close relationship between the alkaloids of *Aconitum Napellus* and *A. Japonicum*.

Pharmaceutical Preparations.—Oleate of Aconitine, N. F.; Aconitine Ointment, Br. The two preparations are of the same strength, containing 2 per cent. of crystallized aconitine.

Action and Uses.—Locally applied to mucous membranes, aconitine first causes a prickling, burning sensation, which is followed by anæsthesia of the part. It irritates the conjunctiva and produces mydriasis. When taken internally, its action is practically the same as that of aconite (for action and uses, see Aconitum). Aconitine is so powerful and so uncertain in its action, that it should rarely if ever be prescribed in internal medicine, especially as it possesses no distinct advantage over aconite. An ointment containing from 4 to 8 grains (0.25–0.50 Gm.) of aconitine to 1 ounce (30 Gm.) of lard is sometimes employed by inunction in the treatment of superficial neuralgia, as, for example, supra-orbital neuralgia, or a solution containing 1 grain (0.05 Gm.) of the alkaloid in 2 fluidrachms (8 Cc.) of alcohol, may be applied with a camel's-hair brush. Care should be taken in its application. Only a small quantity should be used, and it should never be applied upon an abraded surface lest it be absorbed and produce its powerful constitutional effects.

The dose for internal use is generally stated to be from $\frac{1}{200}$ to $\frac{1}{100}$ of a grain (0.0003–0.0005 Gm.); but because of its variable composition this dose should be used cautiously. As much as 2 grains have been taken without producing an untoward effect, while $\frac{1}{100}$ of a grain (0.0006 Gm.) has caused death.

ACONITUM, *U. S.*—Aconite; German Aconite.

Aconiti Radix, Br.; *Tubera Aconiti*, P. G.; *Monkshood, Wolfsbane, Wolfroot, Blue rocket, Cuckoo's cap, Friar's cap*, E.; *Aconit Napel*, Fr.; *Eisenhut, Sturmhut*, G.; *Radix Napelli*, Russ.; *Aconito*, F. It., Sp.

The dried tuberous root of *Aconitum Napellus* L. (Fam. *Ranunculaceæ*), collected in autumn; yielding, when assayed by the U. S. P. process, not less than 0.5 per cent. of aconitine.

Official in all pharmacopœias. The U. S. P. demands that, when assayed by the process given below, it shall yield not less than 0.5 per cent. of aconitine. The Italian requires that it contain 0.2–0.8 per cent. of aconitine. The British requires that it be collected in the autumn from plants cultivated in Britain, but this supply is incapable

of yielding more than a small fraction of what is used under that Pharmacopœia. The French recognizes *A. ferox* Wall.

Description.—Conical, 5 to 10 Cm. (2 to 4 In.) long, or tapering to a greater length, and 1 to 2 Cm. ($\frac{2}{3}$ to $\frac{4}{5}$ In.) thick at the crown, longitudinally wrinkled, dark brown, marked with the white scars of scattered coarse roots; occasionally split to facilitate drying; fracture short; internally whitish, more or less starchy, the bark rather thick, the central axis about 7-rayed and with 5 to 7 small vascular bundles; odorless; taste sweetish, then acrid, producing a tingling sensation, followed by numbness which persists for some time.

The powder is yellowish-gray and odorless or nearly so. Its important elements are small starch-grains, the compound ones 10 to 20 mikrons, the single 5 to 15 mikrons (Jelliffe); colorless stone-cells; spiral, reticulated, and border-pitted vessels; and brown endodermal cells.

Fig. 3.

Japanese aconite (Nat.).

Fig. 4.

Tubers of *Aconitum Napellus* L. with a transverse section (Nat.).

The B. P., in forbidding the presence of any portions of the stem, and requiring that of an undeveloped terminal bud, as well as a starchy and not hollow or spongy interior, specifies an autumn-collected tuber, but it is by no means certain, though generally believed, that such an one is richest in aconitine. On theoretical grounds alone, an abundance of starch should decrease such percentage. One of the richest specimens which ever came into our possession was hollow and shrivelled.

The Aconite Plant.—The seedling aconite does not flower until after it has developed the perfect tuber elsewhere described, and this is said not to occur before the third year. The plant is smooth, except for a very slight pubescence toward the summit. The flower-stem is thrown up from a bud which terminates the tuber. It rises to a height of 2 to 5 feet, and may be either simple or productive of a number of erect or strongly ascending flower-branches, forming a very handsome paniculate inflorescence, for which it often is cultivated. The radical leaves are very long-petioled, the stem-leaves developing successively shorter petioles until they become sessile toward the summit. The lowest leaves are nearly circular in outline, with a deeply and narrowly cordate base, often 6 inches or more in diameter, palmately 3-parted, the segments again 3-parted, and these divisions 2- to 3-lobed, the lobes toothed and more or less pointed. The ultimate divisions are thus linear or narrowly oblanceolate, thickish, and grooved along the midrib upon the upper surface. The upper leaves become smaller, reduced at length to 2 inches in diameter, and less divided, until finally only 3-lobed or 3-parted, and all the sinuses broader. The showy, deep-blue flowers, of peculiar hooded form, and the 3-celled capsule are shown in Fig. 5.

During the flowering period, the tuber is becoming exhausted of its stored nourishment, chiefly starch, and a new or "daughter" tuber is developing from it by means of a lateral bud near the crown. This bud develops into a rhizome so short as to leave the 2 tubers almost or quite in contact. The free end of the rhizome enlarges, developing a thickened stem-base with concealed terminal bud and a long vertically descending root, which together gradually develop into a resemblance to the parent tuber. The aconite drug is, therefore, a combination of rhizome and root, although the term "tuber" is properly applicable to it. It is obvious that the condition and appearance of the parent and daughter tubers will vary according to the stage of development when collected. At the close of the season, the daughter tuber will look exactly as the parent did at the beginning of the season, with an undeveloped terminal bud. At the same time, the parent will have become a shrivelled shell, with the hollow exhausted stem attached to its summit. Autumn-collected tubers, strictly speaking, will, therefore, be free from both stem-development and the skeleton of the parent. If collected when in flower, the daughter will be rather small, while the parent will

be somewhat hollow and deeply and coarsely wrinkled, chiefly longitudinally, with the roots either attached or showing scars where broken off, and surmounted by a stout, strong, hollow stem-base. The two may be attached, or, as is more usual, separated.

Fig. 5.

Aconite plant (⅓ Nat.); flower and fruit (⅔ Nat.). (After Baillon.)

The aconite plant is not likely to be mistaken for any other, except through gross carelessness, as in a case in which poisoning occurred through mistaking it for celery. The statement has been published and has become widely copied in text-books, that poisoning by aconite has occurred frequently through mistaking its tubers for horse-radish, and there is fairly good evidence that such mistakes have occurred, though very rarely. They are difficult to explain, since there is almost no resemblance between the white, nearly cylindrical and large root of the latter and the small conical brownish tuber of aconite.

Notwithstanding the numerous statements which have been published upon the subject and the great amount of work which has been done in studying the constituents of aconite, the distribution of the alkaloids during the different stages of its development and exhaustion cannot be considered as determined, nor, therefore, the relative medicinal value of the root as collected at different periods. So far as the wild tuber is concerned, collection easily admits of confusion and admixture with other species growing in the same locality, especially *A. variegatum.* To avoid this accident, it is demanded elsewhere that collection be made when the plant is in full flower, when identification is comparatively easy. When the plant is cultivated, such danger of confusion does not exist, and it is unfortunate that we have not some fully determined rule regarding the period of collection. Aconite is extensively cultivated both on the continent and in England, and opinions differ as to the relative activity of the wild and cultivated drugs. Certainly the cultivated English drug has been proved of good quality.

The official species of aconite grows only in the lower mountain regions of central Europe, although it is stated in various works that it grows in western North America and in India. Works on the flora of India generally state that several varieties of *A. Napellus* grow there, some of them being highly poisonous, while others are not at all so. Even in the absence of any specific knowledge of these forms, we should not hesitate to deny the possibility of their pertaining to this species, under the existing conditions, and we must pronounce *A. Napellus* as being purely a European plant.

Substitutes and Adulterants.—The only species growing with *A. Napellus* in such a way as to be liable to admixture is *A. variegatum.* This tuber is usually smaller than the official variety, but closely resembles small specimens of it, and its detection by the ordinary pharmacist is extremely unlikely. Japanese aconite, from *A. Fischeri* Reichb., is imported quite largely into Europe, and frequently finds its way to the United States. Its characteristic form, size, and surface are well shown in Fig. 9, contrasted with those of the official tuber. Its surface is of a rather light-gray color, and distinctly plump and smooth. Its starch-grains are nearly twice as large as those of the official tuber. Indian aconite, from *A. ferox* Wall., scarcely ever is seen in this country, and need hardly be guarded against. It is of great size, from 4 to 6 inches long and one-third as thick. It is nearly black upon the surface, yellowish just underneath it, and brownish-red internally, showing darker imbedded masses. The texture is very hard and has a resinous fracture. The pith is small and surrounded by a circular fibro-vascular zone inside of the principal star-shaped zone.

The principal characteristics of the official tuber, distinguishing it from others, are its elongated or slenderly conical shape, the very heavy longitudinal wrinkling of most

of the older tubers, the dark-brown color, and particularly the very short white stumps, chiefly toward the crown, where the roots have been broken off.

Constituents.—The active constituent of aconite is the crystallizable alkaloid *aconitine* (*napaconitine*), elsewhere discussed. With it are large and apparently variable amounts of its 2 derivative non-crystallizable alkaloids *benzaconine* (*picraconitine* or *isaconitine*, at least in part) and *aconine*. Another, *napelline*, has been reported as a derivative intermediate between the two last mentioned, while others have claimed that it is identical with the last. The presence of a fourth derivative has also been regarded as probable. The percentage of total alkaloids appears to vary widely, but has been estimated very differently by different analysts, even when their average results are considered and when the same processes were followed, so that it must be doubted if such processes are adapted to successful general use. Our best information points to about 0.75 per cent. as the probable average. Keller reported it a little more than 1 per cent. The normal relative amounts of the several alkaloids are still more uncertain. Decomposition is effected so readily as to have vitiated the results of many experiments. Dunstan reported (*Pharm. Jour.*, March 18, 1893) that at least 75 per cent. of the total alkaloids might be regarded as amorphous, which would make the average of aconitine about 0.2 per cent. The point is of great importance, since not only is benzaconine inert, but aconine even appears to be antagonistic to aconitine in its cardiac effects. Aconitine is reported by Richards and Ashley (*Chem. and Drug.*, 38 [1891], 205 and 242) as occurring in the cambium, vascular bundles, and sieve-tubes. Dunstan (*loc. cit.*, 1892, 265) states that very little of it is contained in the expressed juice. An abundant constituent is *aconitic acid* ($H_3C_6H_3O_6$), chiefly in combination with calcium, and practically inert. It is soluble in water, alcohol, and ether, and crystallizes in colorless plates or warts. It occurs abundantly in this family, especially in *Adonis* and *Delphinium*, as well as in other families. It can be prepared from citric acid by heating it rapidly in a retort until oily streaks appear in the neck, when the residue is exhausted with ether. The percentage of starch is most variable, depending largely upon the stage of development when collected. Resin, fat, sugar, and a little mannite also occur.

The Aconite Herb.—The herb or leaves of aconite, though no longer official, nor recognized by good authority as suitable for use, are still collected and used upon a very extensive scale. No other description of them is necessary than that of the plant, already given. They should be collected during the flowering period. Their composition is in general similar to that of the tuber, but the average amount of total alkaloids is not greater than 0.25 or 0.5 per cent.

Assay of Aconite.—Aconite, in No. 40 powder, 10 Gm. alcohol, distilled water, ether, ammonia-water, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin test-solution, of each a sufficient quantity. Introduce the aconite into a 200 Cc. Erlenmeyer flask, add 75 Cc. of a mixture of alcohol, 7 parts, and distilled water, 3 parts (by volume), stopper the flask securely, and agitate it at intervals during 4 hours. After placing a plug of cotton in the bottom of a small cylindrical glass percolator (25 Mm. in diameter), carefully transfer the contents of the flask to the percolator. When the liquid has all passed through, continue the percolation with more of the same menstruum until 150 Cc. of the percolate have been obtained. Pour the percolate into a shallow porcelain evaporating dish, and evaporate it to dryness at a temperature not exceeding 60° C. (140° F.). Add 5 Cc. of tenth-normal sulphuric acid solution and 10 C. of distilled water. When the extract is dissolved, filter the liquid into a separator, washing the dish, and filter with about 40° Cc. of distilled water. When this has passed through, add 25 Cc. of ether and 2 Cc. of ammonia-water to the separator, and agitate for one minute. Draw off the lower layer into a flask, and filter the ethereal solution into a beaker. Return the contents of the flask to the separator, add 15 Cc. of ether, and agitate for one minute. Draw off the lower layer into the flask, and filter the ethereal solution into the beaker. Repeat the shaking out with two other portions of 10 Cc. each of ether. Evaporate the combined ethereal solutions to dryness, and dissolve the residue in 3 Cc. of tenth-normal sulphuric acid solution. Add to the solution 5 drops of hematoxylin test-solution, and then carefully run in fiftieth-normal potassium hydroxide solution until a violet color is produced, the transition stages being as follows: first yellow, then green, finally passing into violet. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 3 (the 3 Cc. of tenth-normal acid used), multiply the remainder by 0.064, and this product by 10 (or multiply at once by 0.64), which will give the percentage of alkaloid in the aconite.—U. S.

The addition of about 5 Gm. of powdered pumice to the percolate before evaporation will be found to facilitate solution of the residue in the acid and also the subsequent filtration.

Pharmaceutical Preparations.—Fluidextract of Aconite, U. S. P.; Liniment of Aconite, Br.; Tincture of Aconite, U. S. P.

Action and Uses.—Aconite when locally applied to either skin or mucous membrane produces a tingling sensation in these parts, which is probably due to a primary stimulation of the end-organs of the sensory nerves, but which in a short time is followed by depression of their acuity. The drug acts as a local anæsthetic, but is too irritating for use upon mucous membranes, especially that of the eye. In full medicinal dose it may cause salivation and epigastric pain. It is stated that the drug possesses diaphoretic properties, but it probably has no direct influence upon the sweat-glands, the perspiration induced being the result of capillary depression and relaxation. In susceptible individuals the drug sometimes produces pruritus, or vesicular or pustular eruptions. Internally its dominant action is that of a depressant. It depresses the perceptive centres of the brain, the sensory side of the cord, and especially the peripheral ends of the sensory nerves. Poisonous doses paralyze the motor side of the cord and the motor nerves. Reflex action is decreased. The pulse is slowed by a direct depression of the heart-muscle and by stimulation of the pneumogastric nerve. Blood-pressure is lowered by the depressant action of the drug upon the heart itself. Aconite probably has no effect upon the vasomotor center unless given in very large doses, when it acts as a depressant. Temperature is lowered by the increase in heat-dissipation, which is mainly due to impaired circulation; but when the drug is exhibited in large doses the fall in temperature is aided by the capillary relaxation which occurs. Upon the respiration aconite has little effect in moderate amounts, but may be considered a depressant rather than a stimulant. In overdoses it produces death by respiratory paralysis. In febrile states the drug increases urinary flow, but in the normal individual it has no effect upon this secretion. Aconite is absorbed rapidly and destroyed in the body by oxidation, its effects usually lasting about 3 hours.

Aconite may be used with benefit in the early stages of all acute inflammatory conditions; as, for example, in beginning lobar pneumonia, quinsy, tonsillitis, spasmodic croup, and certain types of asthma, depending upon spasm without depression of the heart. In the sthenic fevers of children, where the pulse is full and bounding and the reflexes exaggerated, it may be given with benefit. It is of value in menstrual suppression due to exposure to cold. Frequently pericarditis in its early stages and cardiac palpitation are influenced favorably by its use. Locally, in the form of the oleate of aconitine, it has been employed in superficial neuralgias. The drug should never be used in asthenic conditions, and unless used in the very earliest stages is contraindicated in acute inflammations.

In poisonous dose aconite produces first a tingling sensation in the mucous membrane with which it comes in contact. This is followed shortly by severe burning pain in the mouth, œsophagus, and stomach. There occurs a tingling sensation, followed by numbness of the lips, finger-tips, or over the entire surface of the body. Vomiting and purging rarely occur, muscular relaxation is common, and the reflexes are greatly depressed. Exophthalmos may be present, the sclerotic coat of the eye presents a pearly luster, and the pupils may be either normal, contracted, or dilated. Syncope may occur, or the patient may retain consciousness until death takes place. The respirations are slow and shallow. The pulse at first is slow, but later becomes running, rapid, and thready. The face is pallid, and the surface of the body becomes covered with a cold, clammy sweat. The temperature becomes abnormal. Occasionally there may be stiffness or spasm of the muscles, or even clonic convulsions. Death may occur from respiratory failure, or sudden exertion on the part of the patient may cause sudden death, the heart stopping in wide diastole. When poisonous doses of aconite have been taken, the patient should at once be placed in a prone position. If possible, the head should be on a lower level than the feet. If seen early, the stomach-pump or syphon may be used with benefit. If vomiting occur, it should be into a towel, the patient remaining prone, with the head turned to one side but not elevated. The application of external heat by means of hot-water bottles or bricks is essential. The administration of alcohol, ether, or ammonia, followed by digitalis, may be resorted to to support the heart. Strychnine may be given with advantage both as a circulatory and respiratory stimulant.

Aconite is given most commonly in the form of the tincture, in the dose of 3 to 15 minims (0.20–1 Cc.). The dose of the extract is from $\frac{1}{10}$ to $\frac{1}{2}$ grain (0.005–0.025 Gm.); of the fluid extract, from 1 to 2 minims (0.05–0.10 Cc.).

The best results probably are obtained by its administration in divided doses frequently repeated.

Other Species of Aconite.—The genus *Aconitum* L. is credited with the possession of some 60 species, widely distributed throughout the Northern hemisphere. They do not generally agree in their composition and properties, some of them being used even as articles of food. The two most important species, *A. Fischeri* Reichb., yielding Japanese aconite, and *A. ferox* Wall., yielding the most important of the Indian aconites, are known in India as *bish*, *bikh*, or *bachnag*. Japanese aconite contains as its active constituent an alkaloid which has been called *japaconitine*, and which is now generally believed to be identical with aconitine. The Indian aconite here named contains, however, a totally distinct alkaloid *pseudaconitine* (*peraconitine*), quite as active as aconitine, and its action is in general similar.

A. LYCOCTONUM L., of Europe and northern Asia, is actively poisonous. The alkaloids *lycoctonine* and *acolyctine* have been reported in it. The former is probably in part at least pseudaconine, the latter uncertain and very similar to napelline.

A. HETEROPHYLLUM Wall. is another Indian species, very abundant in the northwestern Himalayas at from 7000 to 10,000 feet, where it is known by the name of *atis*. It contains the alkaloid *atisine*, which is not poisonous like aconitine. In its native home it is used largely as an antiperiodic.

A. PALMATUM Don. is found in Sikkim, India, where it is known as *seto-bikhoma*. It is sold largely under the name of *bikhma* or *bishma*, and is used like the last.

A. NAPELLUS L. does not, as already stated, occur in India, though several so-called varieties of it are there found. Watt states that the more western of these varieties are poisonous, while those of the east are not. Of the latter, the var. *multifida* and var. *rotundifolia* yield tubers which are rather important articles of food among the natives.

A. SEPTENTRIONALE Koelle, of northern Europe, has been considerably studied and 3 alkaloids have been extracted from it, but it is not safe to attempt to define their resemblance to other alkaloids of the genus.

ADEPS, *U. S.*, *Br.*—Lard.

Adeps suillus, P. G.; *Axungia porci*, *Axungia.*—*Graisse de Porc*, *Axonge*, *Saindoux*, Fr.; *Schweineschmalz*, G.; *Grasso Suino*, *Sugna*, It.; *Grasa de Cerdo*, Sp.; *Banha*, Port.

The prepared internal fat of the abdomen of *Sus Scrofa* L. (class *Mammalia*; order *Pachydermata*), purified by washing with water, melting, and straining.

Lard should be kept in well-closed vessels impervious to fat, and in a cool place.

Description.—A soft white unctuous solid, having a faint odor free from rancidity, and a bland taste. Insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, or benzin. Specific gravity about 0.917 at 25° C. (77° F.), and about 0.904 at 40° C. (104° F.), water at 25° C. (77° F.) taken as a standard. It melts at 38° to 40° C. (100.4°–104° F.) to a perfectly clear liquid, which is colorless in thin layers, and which should not separate an aqueous layer. At or below 30° C. (86° F.) it is a soft solid.

Distilled water boiled with lard should not acquire an alkaline reaction (absence of alkalies), nor should another portion be colored blue by iodine test-solution (absence of starch). A portion of the water, when filtered, acidulated with nitric acid, and treated with silver nitrate test-solution, should not yield a white precipitate soluble in ammonia (absence of chlorides).

If 10 Gm. of lard be dissolved in chloroform, and the solution mixed with 10 Cc. of alcohol and 1 drop of phenolphtalein test-solution, it should not require more than 0.2 Cc. of normal potassium hydroxide solution to produce a pink tint after strong shaking (limit of free fatty acids).

If 5 Cc. of melted and filtered lard be, while warm, intimately mixed, by agitation, in a test-tube, with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol and adding 2 drops of nitric acid), and the mixture then heated for 5 minutes on a water-bath, the liquid fat should not acquire a reddish or brown color, nor should a dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent. of cottonseed fats).—U. S.

Lard is official in all pharmacopœias, which variously state the melting-point at from 35° to 44° C. (95° to 111.2° F.), and the solidification-point at from 26° to 30° C. (78.8° to 86° F.). The Italian specifies its iodine number at 47 to 48. The British gives the following directions for preparing it, which can hardly be improved upon:

From the perfectly fresh fat of the abdomen of the hog remove as much of the external membranes as possible; suspend the fat so that it shall be freely exposed to the air for some hours; cut it into small pieces; reduce these to a uniform mass in which the membranous vesicles are completely broken, by beating in a mortar or by some similar process; put the mass thus produced into a vessel surrounded by warm water; heat to a

temperature not exceeding 57.2° C. (135° F.) until the fat has melted and separated from the membranous matter; strain.

The principal defects in the quality of lard are (1) the presence of an excessive amount of water; (2) that of potassium carbonate or other alkali carbonate, added to cause it to take up such water; (3) rancidity, resulting from decomposition of the fat, with the production of free acid; (4) the presence of common salt, added to prevent such rancidity or to remove the odor caused by it; (5) the presence of starch; (6) the presence of other fats, more especially of cotton oil. The detection of each of these is provided for in the official description quoted above.

Composition.—The most important of the constituents of lard is stearin, which is associated with variable amounts of olein and palmitin, and the larger or smaller percentage of which renders the lard more or less firm in consistency. Both the liquid (lard oil) and the solid (stearin) portions of lard are articles of commerce upon a very extensive scale. They are separated by pressure, at or about the freezing temperature of water.

Pharmaceutical Uses.—Lard is extensively employed as a vehicle in the preparation of ointments, either alone or in admixture with wax or wax and resin. It should be preserved in impervious containers of glass or porcelain, and be kept in a dry and moderately cool place. Dehydrated lard is to be preferred on account of its freedom from water; it is prepared by melting prime leaf lard with just sufficient water-bath heat, and then adding some substance having great affinity for water, but not affecting the lard itself, such as dried calcium sulphate, or anhydrous calcium chloride, sodium sulphate, or magnesium chloride. After keeping the melted lard in contact with the dehydrating agent for an hour or longer, with frequent stirring, it is carefully strained and then stirred until cool. If much water be present in the lard, a dense liquid layer is likely to be formed on the bottom of the dish if either of the three last-named salts be used, from which the lard can be readily poured off. Dehydrated lard is now manufactured on a large scale and offered in packages of convenient size.

Action and Uses.—When applied to the skin by inunction, lard is perhaps to a certain extent absorbed. Locally, it acts as an emollient, and has been employed as a protective for abraded surfaces, burns, and scalds. In scarlet fever lard has been used to anoint the body during desquamation, but on account of its tendency to become rancid is now seldom used.

ADEPS BENZOINATUS, *U. S.*—Benzoinated Lard.

Adeps benzoatus, Br., P. G.; *Unguentum benzoini*, *Axungia balsamica s. benzoinata s. benzoata.*—*Benzoated lard*, *Ointment of benzoin*, E.; *Axonge (Graisse) benzoinée (balsamique)*, Fr.; *Benzoe Schmalz*, G.; *Grasso con benzoino*, It.; *Manteca con benjui*, Sp.

Hog's lard impregnated with benzoic acid and the odorous principle of benzoin.

Preparation.—Benzoin, in coarse powder, 20 Gm.; lard, 1000 Gm. Add the benzoin to the lard; then melt the lard by means of a water-bath, and, stirring frequently, continue the heat for 2 hours, covering the vessel and not allowing the temperature to rise above 60° C. (140° F.). Lastly, having removed the benzoin, strain the lard, and stir while cooling. When benzoinated lard is to be kept or used during warm weather, 5 per cent. (or more if necessary) of the lard should be replaced by white wax.—U. S.

Take of lard, 1 pound; benzoin, reduced to coarse powder, 210 grains. Melt the lard by the heat of a water-bath, add the benzoin, and, frequently stirring them together, continue the application of heat for 2 hours; finally, remove the residual benzoin by straining.—Br.

Dissolve 1 part of benzoic acid in 99 parts of lard, previously melted on a water-bath.—P. G.

The result of the U. S. and Br. processes is practically identical, though the first formula directs for 1 pound avoirdupois only 140 grains of benzoin. By enclosing the benzoin in a muslin bag and regulating the temperature, it is more thoroughly exhausted than if allowed to melt, and empyreuma is prevented.

Much of the commercial lard is of inferior quality, containing water and other impurities. Only prime leaf lard should be used and the temperature be kept within the prescribed limits. A perfectly smooth preparation can be obtained only if the

strained lard be constantly stirred until a thick, creamy consistence is reached, after which it may be set aside until cold. In our experience very satisfactory results are obtained if a concentrated solution of benzoin 1 part in alcohol 2 parts (by weight) be used in place of the powdered benzoin. Of such a solution, 450 grains may be added to 1 pound of lard, melted on a water-bath, and a moderate heat, not above 50° C. (122° F.), continued for 2 hours or more, until, with occasional stirring, all traces of alcohol have been dissipated. The resinous matter will all deposit on the bottom of the dish, and the fluid lard may then be strained through muslin and stirred until cold. Like all fats, benzoinated lard should be kept in glass or French porcelain jars in a moderately cool, dry place.

Fixed oils and other fats dissolve the benzoic acid and odorous principles contained in benzoin, which protect them against rancidity.

Action and Uses.—Except for the fact that its odor is less offensive, and that it does not become rancid so rapidly, benzoinated lard has no apparent advantage over adeps. The small quantity of benzoin present is not capable of exercising any marked medicinal action.

ADEPS LANÆ, *U. S.*, *Br.*—Wool Fat.

Adeps lanæ anhydricus, P. G.—*Suint de laine*, Fr.; *Wollfett*, G.

The purified cholesterin-fat of sheeps' wool.

Occurrence.—The wool of sheep contains a natural grease, known as *suint*, which consists largely of insoluble fatty matter and a soluble soap, and is obtained in the process of washing the wool. Some varieties of wool yield more than half their weight of fat. Impure wool fat was used centuries ago under the name of *œsypum*. Natural wool fat contains about 30 per cent. of free fatty acids and numerous fatty acid esters of cholesterin and other alcohols. The cholesterin compounds are the constituents chiefly sought. For the purpose of purification, crude wool fat is treated with weak alkali solutions and the resulting emulsion centifruged, whereby an aqueous soap solution is obtained, on which a creamy layer of fairly pure wool fat is found floating. The creamy layer is removed and treated with calcium chloride, after which the fat is separated and dehydrated by fusing in the presence of unslaked lime. Acetone is employed to extract the pure wool fat from this mixture, and yields the same upon subsequent distillation of the solvent.

Properties and Tests.—Wool fat occurs as a brownish or yellowish fatty substance, inclined to be somewhat tough, and is miscible with 2 or 3 times its weight of water, yielding a light-colored, almost white mass of the consistence of a soft ointment. The U. S. P. describes it as a yellowish, tenacious, unctuous substance, having a slight peculiar odor (almost inodorous, Br.), melting at about 40° C. (104° F.) (40°–44.4° C. (104°–112° F.), Br.), and readily soluble in ether or chloroform, but sparingly soluble in cold alcohol. A solution in chloroform (1 in 50) poured gently over the surface of sulphuric acid acquires a deep brownish-red (purplish-red, Br.) color. The following tests for impurities are given: "When wool fat is incinerated it should leave not more than 0.3 per cent. of ash, which should not show an alkaline reaction to litmus (freedom from alkalies). If 2 Gm. of wool fat are dissolved in 10 Cc. of ether, and 2 drops of phenolphthalein test-solution be added, a colorless liquid should be obtained (absence of free alkalies), which, on the addition of 1 drop of normal potassium hydroxide solution, should develop a deep-red color (absence of free fatty acids). If 1 Gm. of wool fat be boiled with 20 Cc. of alcohol, and the solution filtered after cooling, the filtrate should not be rendered turbid by the addition of an alcoholic solution (1 in 20) of silver nitrate (absence of chlorides). If 10 Gm. of wool fat be heated with 50 Cc. of water on a bath of boiling water until completely fused, the lower aqueous layer, when filtered through a well-wetted filter, should not yield glycerin on evaporation, and when boiled with potassium hydroxide test-solution it should not give off vapors of ammonia (absence of organic nitrogenous matter)."—U. S. "1 Gm. should dissolve almost completely in 75 Cc. of boiling alcohol (90 per cent.), the greater part separating in flocks on cooling. 10 Gm. dissolved in 25 Cc. of ether, 2 drops of solution of phenolphthalein being added, should not require more than 0.1 Cc. of volumetric solution of sodium hydroxide to produce a permanent red coloration (limit of acidity). Heated

with solution of sodium hydroxide, no ammoniacal odor should be evolved (absence of nitrogenous animal matter)."—Br.

The description and tests of the P. G. are practically identical with the preceding. A characteristic test for wool fat is the following, known as Liebermann's cholestol reaction: If 1 Gm. of the fat be dissolved in 3 to 4 Cc. of acetic anhydride (not anhydrous acetic acid), and 6 drops of concentrated sulphuric acid be added, a pink coloration will ensue, soon changing to green or blue.

Pharmaceutical Uses.—Anhydrous wool fat is used chiefly for preparing the hydrous variety. It is admirably adapted for admixture with other fats when larger quantities of water or aqueous solutions are to be incorporated.

Uses.—For uses, see ADEPS LANÆ HYDROSUS.

ADEPS LANÆ HYDROSUS, *U. S., Br.*—Hydrous Wool Fat.

Adeps lanæ cum aqua, P. G.; *Lanolinum.—Lanolin,* E.; *Wasserhaltiges Wollfett,* G.

The purified fat of the wool of sheep (*Ovis Aries* L.; class *Mammalia;* order *Ruminantia*), mixed with an amount of water not exceeding 3 parts of the latter to 7 parts of the former.

These proportions are identical with those ordered by the British Pharmacopœia, whereas the German Pharmacopœia directs that 75 parts of anhydrous wool fat shall be mixed with 25 parts of water.

Perfect admixture is best effected by placing the wool fat in a warm mortar and adding the water gradually with constant stirring.

When heated, hydrous wool fat separates into an upper oily and a lower aqueous layer.

Description.—A yellowish-white or nearly white ointment-like mass, having a faint, peculiar odor. Insoluble in water, but miscible with twice its weight of the latter without losing its ointment-like character. With ether or chloroform it yields turbid solutions which are neutral to litmus-paper. Hydrous wool fat melts at about 40° C. (104° F.). When heated on a water-bath, it leaves a residue amounting to not less than 70 per cent., which is transparent while melted, and when cold appears as a yellow tough, unctuous mass, completely soluble in ether or chloroform, and only sparingly soluble in alcohol. If hydrous wool fat be thus deprived of water, it should respond to the tests given under ADEPS LANÆ. —U. S.

Defects in the quality of lanolin are very similar to those in lard, and their detection is provided for by the above official tests.

Action and Uses.—Lanolin is principally used as an ointment base. As it does not become rancid, it has certain apparent advantages over many other ointment bases, and can be used with many chemical substances, as, for example, peroxide of hydrogen, with which lard cannot be employed. When applied to the epidermis by inunction, it is slightly absorbed. It is questionable whether or not this substance is more rapidly absorbed than other fats, the general opinion at present being that in this respect it has no advantage over lard.

ADONIS.—Adonis.

Bird's-eye, False hellebore, Ox-eye, Pheasant's eye, E.; *Adonisröchen,* G.; *Adonide,* Fr., It.

The herb of *Adonis vernalis* L., *A. æstivalis* L., and *A. annua* L. (*A. autumnalis* L.—Fam. *Ranunculaceæ*).

Adonis should be collected when in full bloom and dried in the shade. The two first-named species are natives of Europe and Asia; the third, of southern Europe only. All are more or less cultivated for ornament. *A. annua* is also called *Red morocco, Red mathas, Red camomile,* and *Rose à rubie.* It has crimson-red flowers, while those of *A. vernalis* are bright-yellow and those of *A. æstivalis* are orange. *A. vernalis* is perennial, the others annual. Similar constituents and properties have been found in several others of the 12 or 13 species.

Description.—Stems 10 to 25 Cm. (4 to 10 In.) long, terete, leafy, those of *A. vernalis* having only sheathing scales below; leaves repeatedly pinnatifid, the segments almost capillary, smooth except in *A. vernalis,* where, like the sepals, they are pubescent, especially when young; sepals 5, petals 5 to 15, clawed (oblong and subdenticulate in *A. vernalis*); stamens numerous and pistils several.

Constituents.—Adonis contains about 10 per cent. of aconitic acid. *Adonidin* or *adonin* is the so-called active principle of commerce, which was obtained by Mordagne to the extent of 2 Gm. from 10 Kg. It occurs in all parts of the plant. It is a crystalline, very bitter powder, of a variable shade of yellowish-white, becoming yellow over sulphuric acid and brown upon heating. It is nearly insoluble in chloroform, benzene, and oil of turpentine; sparingly soluble in ether, but freely soluble in water and alcohol. Placed upon moistened blue litmus-paper, it changes the color to red. The watery solution is precipitated by tannin and basic lead acetate, but not by normal lead acetate. Sulphuric acid imparts a brown color, changing to violet. It is a mixture, ascertained by Podwissotzki (1888) to consist of yellow *adonidoquercitrin*, *adonidodulcit* (adonit [$C_5H_{12}O_5$]?), *adonitic acid*, and a brown glucoside, with the active principle *picradonidin*, which is an amorphous glucoside, soluble in water, alcohol, and ether, strongly bitter, and a powerful heart poison; its solution is not disturbed by lead salts, but is precipitated by tannin.

FIG. 6.

Adonis vernalis (½ Nat.).

Pharmaceutical Preparation.—FLUIDEXTRACT OF ADONIS, N. F.

Action and Uses.—Adonis is chiefly used in medicine as a substitute for digitalis in those cases in which idiosyncrasy or other causes prevent the administration of the latter. Like digitalis, it is an irritant to mucous membranes, and it may cause nausea, vomiting, and purging. The chief action of adonis is upon the circulation. It slows the heart, increases the force of the heart beat, and stimulates the vasomotor system, causing an increase in blood-pressure. The drug acts as a diuretic, increasing principally the watery constituents of the urine.

Adonis may be tried in cardiac dropsy, and has been given with asserted success after digitalis and other remedies had failed. It may be tried in all cases of cardiac incompetency in which the more common remedies have failed or in which because of idiosyncrasy or cumulative action they cannot be exhibited.

The dose of adonidin is from $\frac{1}{10}$ to $\frac{1}{4}$ grain (0.005–0.015 Gm.).

An infusion made from all portions of the plant, $\frac{1}{2}$ to 2 drachms in 6 fluidounces (2–8 Gm. in 180 Cc.) of water, may be given in 4-drachm (16 Cc.) doses every 4 hours.

ADRENALINUM.—Adrenalin.

The name adrenalin was applied in 1901 to a crystalline substance obtained independently by Takamine and Aldrich from the suprarenal gland of beeves, and claimed to be the active blood-pressure-raising principle of the gland.

Much work has been done during the past 5 or 6 years with a view to determine the character of the constituent to which the remarkable physiological activity of the suprarenal gland is due, and since 1896 several substances have been isolated by different investigators. These substances are not identical in every respect, but strongly resemble each other, and have been designated by different names. The earliest publication on the active principle of the suprarenal gland was by J. J. Abel (*Johns Hopkins Hospital Bulletin*, 1897), who applied the name epinephrin to this product. In 1898 von Fuerth called attention to a substance which he claimed to be different from the preceding, and which he named suprarenin. As stated above, in 1901 the crystalline substance adrenalin was brought to the notice of the medical world. Abel's first product was later found to be a monobenzoyl derivative of the native substance, the result of incomplete saponification of a benzoylated compound made with the view of obtaining a purer product.

The following methods of manufacture have been suggested:

According to Takamine, adrenalin, to which he assigned the formula $C_{10}H_{15}NO_3$, is prepared as follows:

Suprarenal capsules, finely minced, are digested in water acidulated with hydrochloric or acetic acid for 5 hours at a temperature of about 70° C. (158° F.), with frequent agitation. At the end of that time the temperature is raised to 90° C. (194° F.) for an hour, for the purpose of coagulating the albuminoids present. A layer of fat is preferably kept floating on the surface of the mass during digestion, to protect the active constituent against oxidation by the air. The mixture is now expressed and the residue again digested for several hours in slightly acidulated water, and again expressed. Having mixed the expressed fluids and separated any fat present, the clear extract is concentrated, preferably in a vacuum apparatus, and mixed with 2 or 3 times its volume of alcohol (or wood alcohol), whereby inert matter is precipitated. After separation and washing of the precipitate with alcohol, the alcohol is recovered by distillation, 10 per cent. ammonia water is added to the residual liquid, and the mixture set aside for several hours. Crude adrenalin is precipitated as a brownish-yellow crystalline mass, which may be purified by re-solution in alcohol and acid, and subsequent addition of ether. After filtration for removal of precipitated impurities, the filtrate is again made alkaline with ammonia water, when a nearly white crystalline precipitate of adrenalin will separate, and may be washed with water and then with alcohol, and dried (*Am. Jour. Pharm.*, Nov., 1901).

The following method of Aldrich differs slightly from the preceding, and evidently yields a purer product:

Finely divided suprarenal glands are repeatedly extracted, at a moderate temperature, with water acidulated with acetic acid. The united extracts are heated to boiling, and, after cooling, the coagulated proteids are removed by filtration, the filtrate being evaporated in a vacuum at 45° C. (113° F.) to a small volume. Lead acetate is now added to complete the precipitation of inert matter, which is removed by filtration, and the excess of lead gotten rid of by passing hydrogen sulphide into the filtrate. The clear liquid having again been evaporated to a small bulk, 4 or 5 times its volume of 94 per cent. alcohol is added, the mixture filtered, and the alcoholic filtrate evaporated to a very small bulk, or even to dryness, taken up with water and filtered. To this filtrate ammonia water is added, which causes a precipitate in the form of small lumps with radial markings, or as individual crystals. The precipitate is washed with very dilute ammonia water by decantation and then on a filter with cold water until all alkali is removed, after which it is dried in air or in vacuo (*Am. Jour. Physiol.*, Aug. 1, 1901).

Aldrich has assigned the formula $C_9H_{13}NO_3$ to this product.

Abel (*Johns Hopkins Hospital Bulletin*, Feb.–March, 1902) states that a pure crystalline form of his epinephrin may be obtained thus:

A highly concentrated slightly acidulated aqueous extract of suprarenal glands is mixed with absolute alcohol, actively shaken, and after standing a few hours is filtered. Upon recovering the alcohol under reduced pressure a straw-colored syrup remains, which, on cooling, congeals and is then dissolved in ammoniacal zinc chloride solution. An impure zinc compound of epinephrin is obtained by gradually adding to the solution, while stirring, about 11 times its volume of absolute alcohol, filtering, and drying the slightly reddish-yellow precipitate at 50° C. (122° F.). The powder is dissolved in very dilute acetic acid, hydrogen sulphide added to remove the zinc, and after filtration the liquid is concentrated to a small bulk under diminished pressure. On now adding ammonia water in successive portions until the liquid smells strongly and permanently of ammonia, a crystalline compound is obtained, which is separated by filtration without delay, and may be still further purified by repeated solution in hydrochloric acid and reprecipitation by ammonia.

This crystalline product obtained by Abel's zinc-ammonia process is undoubtedly identical with adrenalin. Both substances fail to react with alkaloidal reagents; but if hydrolyzed in an autoclave at low temperature, they assume alkaloidal properties and are precipitated in an amorphous flocculent condition by ammonia; such precipitate, at first white or yellowish-white, darkens on exposure to air. Neither substance suffers appreciable loss of weight if heated for 2 hours at 60°–125° C. (140°–257° F.), but if heated in dry air to 177°–180° C. (350.6°–356° F.) for 30 minutes, some loss in weight occurs, the color changes to reddish and later to reddish-brown, and the substance is converted into the alkaloidal form (personal communication from Prof. Abel). The same change into the alkaloidal variety may be brought about by treatment in an autoclave, exposure to hydrochloric acid gas, or solution in strong hydrochloric or sulphuric acid. Both bodies, when thus transformed, readily form salts with acids which are difficultly crystallizable, and both energetically reduce Fehling's Solution on boiling. It is claimed by Abel that his own crystalline form of epinephrin as well as adrenalin are both derivatives of the native active principle of the suprarenal gland. More investigation seems necessary to harmonize these and other conflicting views. In a recent article by Aldrich (*Am. Jour. Physiol.*, July, 1902) it is stated that the removal of

adrenalin from a concentrated extract of suprarenal glands, effected without the use of hydrogen sulphide or other reducing agent, by simple direct precipitation with a saturated solution of sodium carbonate, or 10 per cent. ammonia water, very largely (but not entirely on account of incomplete precipitation) destroys the blood-pressure-raising capacity and copper-sulphate-reducing power of the extract, thus pointing to adrenalin as the active principle of the gland. These results, it is claimed, show that the former statement, that the active principle as present in the gland does not reduce Fehling's Solution, is erroneous, as also the suggestion that the action of hydrogen sulphide, or other reducing agent, on the native principle is essential for the development of the copper-sulphate-reducing power.

While the empirical formulas given by Abel, Aldrich, and Takamine for their respective crystalline products vary somewhat, it seems fair to assume that the products are identical, barring possible impurities, since they agree in general properties and behavior toward reagents.

Properties.—Adrenalin occurs on the market as a light-grayish or brownish-white micro-crystalline substance, having a slightly bitter taste and leaving a numb feeling when applied to the tongue. It is difficultly soluble in cold water, but more readily in hot water, the aqueous solution being oxidized by air and becoming colored. Adrenalin in dry form is perfectly stable. On heating, it turns brown at 205° C. (401° F.), and melts, decomposes, and swells simultaneously at 207° C. (404.6° F.). In contact with moistened litmus-paper it shows a weak alkaline reaction, as well as with phenolphtalein. It is easily soluble in acids, forming salts, which thus far it has not been possible to obtain in crystalline form, but merely as a very hygroscopic mass, and is also soluble in potassa solution, but does not dissolve in ammonia or alkali carbonates. Adrenalin is not precipitated by tannic acid, picric acid, mercuric chloride, Mayer's reagent, phosphomolybdic acid, lead acetate, and platinum chloride. In various ways, as by exposure to hydrochloric acid gas, adrenalin can be converted into the alkaloidal variety, which responds to all these alkaloidal reagents. The relationship is evidently a simple one, but at the present time it is impossible to express it in quantitative terms. Ferric chloride colors a solution of adrenalin emerald-green while iodine imparts a vivid pink color. The color reaction with ferric chloride is of a fleeting character, the fine green color soon changing to a dirty brown. Abel has found that the addition of a solution of potassium thio-benzene-sulphonate to a solution of adrenalin or epinephrin causes the green color produced by the iron to persist for a long time, and he has suggested that a quantitative colorimetric method of estimation may be based on this fact. Careful addition of caustic alkali to the green solution colored by ferric chloride causes various shades from purple to carmine-red. Gold chloride is energetically reduced by adrenalin, and complete separation of the metal follows from an acid solution, by application of gentle heat, the liquid assuming a pink or red color, as with nitric acid, potassium dichromate, and other oxidizing agents.

Action and Uses.—Suprarenal gland is sometimes employed in the form of a desiccated powder, more commonly as a liquid extract, and still more commonly in the form of what is known as adrenalin chloride, already described. The influence of adrenalin when injected intravenously is that of a powerful vasoconstrictor, so that it causes a marked rise of arterial pressure. This effect is due to the stimulation of the muscular coat of the bloodvessels, and not to any influence upon the vasomotor centres. Hypodermic injections of it produce similar but less marked effects, and it is probable that its instillation into the eye may be followed by sufficient absorption from the lachrymal and nasal mucous membranes to produce some physiological influence. If held in the mouth, it may also be absorbed; but if swallowed, the gastric juices seem to alter it, so that the internal use of adrenalin for its effect upon the vascular system is not followed, as a rule, by advantageous results. Because of its ability to cause constriction of the bloodvessels, it has been employed for the purpose of overcoming vascular relaxation and surgical shock. For these conditions it is best administered by intravenous infusion or hypodermoclysis in normal saline solution: 1 or 2 drachms (4–8 Cc.) of the 1:1000 solution of adrenalin chloride to 1 pint (480 Cc.) of the saline solution. As infinitesimal quantities of the drug produce a powerful influence upon the muscular coats of the bloodvessels, this solution for intravenous administration should be injected very slowly. Strong solutions should not be used hypodermically, because they produce localized ischæmia at the area of injection, and should this area become infected a slough

may ensue. It increases the force of systole of the heart by stimulation of the cardiac muscle-fibres, but it is rarely if ever used in medicine for its effect upon the cardiac muscle. By far the widest field in the employment of adrenalin is in connection with its influence upon the bloodvessels supplying the mucous membranes in the nose, ear, throat, and eye, and to a less extent in connection with disorders of the capillary network in the mucous membranes of the genito-urinary and alimentary tracts. For these purposes it is always applied locally, in the form of a solution of 1 : 5000 or 1 : 1000 normal saline, although even so weak a solution as 1 : 20,000 may produce distinct physiological effects, and in many instances 1 : 10,000 is a better strength than 1 : 5000. Almost immediately after its application to a mucous membrane, even if it be turgid with blood, the membrane becomes shrunken and blanched through the powerful constriction of its capillaries by the action of the drug. This constriction, as a rule, lasts at least half an hour, and sometimes for several hours, and its action may or may not be followed by a return of the turgescence. Because of this effect of adrenalin it is an exceedingly valuable substance for overcoming local hyperæmias, and for diminishing hemorrhages from mucous membranes in the areas that we have named, or in any area in which there is a capillary hemorrhage. It is worthy of note that if the congestion of a mucous membrane has lasted so long that paralytic dilatation of its bloodvessels is present, adrenalin fails to cause contraction, because the muscular fibers and the walls of the vessels are incapable of contraction by reason of their paralysis. As the influence of adrenalin and cocaine in producing ischæmia is very similar, these two substances are frequently applied together when both local anæsthesia and ischæmia are required. It has been claimed that adrenalin is a local anæsthetic, but any diminution in sensation produced by its influence is probably due more largely to the anæmia of the parts which it produces than through any direct influence which it may exert upon sensory nerve filaments.

Suprarenal gland, its extract, and adrenalin have all been employed internally in the treatment of Addison's disease. In some instances good results have been produced, but the hopes which at first were held, that it might prove a specific in this malady, have been blasted, probably because all cases of Addison's disease are not due to the same cause.

The best way of applying suprarenal extract or adrenalin chloride solutions to mucous membranes is by means of a medicine-dropper, a small atomizer, or by wetting a pledget of cotton which is held in contact with the mucous membrane till the desired effect is produced. Notwithstanding the great power of adrenalin, it has produced few untoward results, and no fatal ones so far as we know. The patient in some instances has complained of disagreeable sensations in connection with the mucous membrane upon which the drug was acting. Very large amounts are capable of causing death if injected intravenously, and somewhat smaller ones produce glycosuria. The dose of the dried extract is from 3 to 5 grains (0.20–0.30 Gm.).

AER.—Air.

The air or atmosphere (from *ἄτμος*, vapor, and *σφαῖρα*, sphere) is the gaseous envelope surrounding the earth which sustains the most intimate relation to animal and plant life. The essential constituents of the atmosphere, which are also indispensable to vegetation, are oxygen, nitrogen, water vapor, carbon dioxide. Other components, occurring in much smaller quantity, are ammonium nitrite and nitrate, argon, helium (two lately discovered elements), ozone, hydrogen peroxide, and a few other substances which are present in very minute quantities. The composition of purified dry air by volume and by weight is:

	Volumes.	Parts by weight.
Nitrogen	78.4	75.95
Oxygen	20.94	23.10
Argon	0.63	0.90
Carbon dioxide	0.03	0.05
	100.00	100.00

The proportions of oxygen, nitrogen, and argon remain constant in the atmosphere in spite of climatic changes, elevation, vegetation, etc. The tendency to diminution of the oxygen by animal respiration is counterbalanced by the life-processes of plants, which liberate oxygen from the carbon dioxide formed in respiration. The percentage of water vapor in air is variable, the average being 0.84. The density of water

vapor is 0.62 (air = 1), hence moist air is lighter than dry air. 1 liter of air freed from water vapor and carbon dioxide weighs 1.29318 Gm. (Regnault) at 0° C. (32° F.) and 760 Mm. pressure.

Air can be liquefied by low temperature and great pressure; for example, —145° C. (—229° F.) and 31.5 atmospheres. In liquid air carbon dioxide solidifies and can be filtered off, leaving a clear liquid composed of liquefied nitrogen, oxygen, and a little argon. In an open vessel the liquid boils or vaporizes, and its temperature falls to —191.2° C. (—312.2° F.), at which point alcohol and ether are solidified. In vaporizing, the nitrogen goes off first, leaving a liquid which gradually becomes richer in oxygen and assumes a blue color. It has been proposed to manufacture oxygen for commercial purposes in this manner from liquefied air. Liquid air is lighter or heavier than water according to the amount of nitrogen that has escaped by vaporization.

While nitrogen and oxygen had been liquefied by Cailletet and Pictet in 1876 (*Compt. rend.*, 85, 851, and 1270) by cooling highly compressed air with an artificial cooling agent, it was not until Linde, of Germany, Hampson, of England, and Tripler, of New York, perfected their machines, about 1898, that liquid air was produced by a continuous process, in any desired quantity. In these machines the cooling of the compressed air is accomplished by the cold produced by expansion of the air when allowed to escape from a tube. This cooled air is made to surround the tube containing the compressed air, which is thus gradually reduced in temperature to such a point that it liquefies.

Liquid air is a very useful cooling agent in some chemical reactions which cannot be carried out at ordinary temperature. In other instances chemical change does not take place at the temperature of liquid air. (For a description of apparatus and experiments with liquid air, see *Ber. d. Deutschen Pharm. Gesell.*, 1901, p. 277; Erdmann's *Anorg. Chem.*, 1900.) Hempel (*Chem. Industrie*, 22, 1) is very sanguine in his prediction that liquid air will be a source of oxygen for industrial purposes in the future. Linde's apparatus can be so modified that the liquid obtained contains about 80 per cent. of oxygen. Liquid air cannot be preserved in air-tight vessels, as explosions would result owing to the increase of pressure as the liquid evaporates. Small quantities are best kept in so-called Dewar vacuum bulbs, which are vessels with double walls having a vacuum between them, the vacuum being a very poor transmitter of heat. The Weinhold vessel is constructed similarly. In such vessels 1–2 liters of liquid air will last from 8 to 14 days, the daily loss being about 100 Gm.

Action and Uses.—Liquid air has been employed as a therapeutic agent for many conditions, but because of the difficulty in handling it, this substance has never been generally accepted by the profession.

It is stated that when micro-organisms are placed in contact with it, their action is held in abeyance for some time, and advantage has been taken of this fact in the treatment of various septic conditions. When locally applied, liquid air acts as a freezing agent and causes anæsthesia; hence it may be employed where minor surgical operations are to be performed. When applied for a sufficient length of time, it acts as a cauterizing agent, and as such has been used in the removal of lupus, nævi, adenoids, and polypi. It is stated that its employment has the distinct advantage of producing little or no scar in the above conditions. This remedy has been employed to abort beginning inflammatory conditions, and in such conditions would appear to be an excellent remedy, as it not only produces excessive cold, but also checks the activity of the invading micro-organisms. The vapor arising from liquid air has been suggested as a substitute for the Brand method in the reduction of temperature; it is probable, however, that it would be inadequate as such, as the reaction from the latter method depends largely upon the friction caused by accompanying massage. This vapor has also been recommended in the treatment of acute bronchitis and laryngitis, tubercular laryngitis, and in pulmonary tuberculosis.

Argon.—Ar. Atomic weight, 39.6; density (air = 1), 1.38.—This element was discovered in the atmosphere in 1894 by Lord Rayleigh, of England. It resembles nitrogen very closely in properties, but is even less active chemically; hence its name argon (from ἄργον, sluggish—*i. e.*, no activity). It forms about 0.9 per cent. of air by weight. It occurs also in the gases from some springs, as at Reykjavik, Iceland; Wildbad, Germany; Harrogate, England; and in many Pyrennes springs. It does not form chemical compounds. Its molecule contains only 1 atom.

Helium.—He. Atomic weight, 4; density (air = 1), 0.14.—This element was recognized by Janssen in 1868 in the chromosphere of the sun by means of the spectroscope, and later also by Lockyer, who called it helium (from ἥλιος, the sun). Ramsay and Cleve, independently of each other, found the gas in the mineral *cleveite*, in 1895. It occurs combined in several other minerals of the rare elements, found chiefly in Scandinavia, and in the free state in very minute quantity in the atmosphere. It stands next to hydrogen in density, being twice as heavy, and resembles nitrogen and argon in its inertness. It does not liquefy at —264° C. (—443.2° F.) (Olszewski). Its molecule contains 1 atom.

ÆTHER, *U. S., Br., P. G.*—Ether.

Æther sulphuricus, Naphtha vitrioli.—Sulphuric ether, E.; *Ether hydrique s. vinique s. sulfurique*, Fr.; *Æther, Schwefeläther*, G.; *Etere*, It.; *Eter sulfurico*, Sp.

Formula, $(C_2H_5)_2O$. Molecular weight, 73.52.

History and Formation.—Ether, or a mixture of ether and alcohol, was probably obtained by the alchemists in the thirteenth century, but a process for its preparation from equal parts of oil of vitriol and alcohol was first devised in the sixteenth century, by Valerius Cordus, who called it *oleum vitrioli dulce verum* (true sweet oil of vitriol). The name "ether" (spiritus æthereus) was first used for this liquid by Frobenius in England (1730). Fourcroy and Vauquelin (1797) regarded ether as alcohol deprived of water by the action of sulphuric acid, and Valentin Rose proved (1800) that ether contains neither sulphur nor an acid. Berzelius explained the action of sulphuric acid upon alcohol by catalytic force. Liebig regarded sulphovinic acid as a double sulphate of water and ethylic oxide (ether), which is decomposed by heat, with the liberation of ether. Rose explained this decomposition by water displacing the ether from the compound mentioned. Graham ascribed the result to the polymerizing power of sulphuric or sulphovinic acid, whereby alcohol ($C_2H_2 + HO$, old notation) is converted into ether ($C_4H_4 + HO$). Williamson (1851) advanced the theory which now prevails, that when alcohol and sulphuric acid are mixed, ethylsulphuric (sulphovinic) acid is formed, which reacting with more alcohol on the application of heat produces ether, while sulphuric acid is regenerated at the same time. The discovery later of ethers containing two distinct alcohol radicals supported this view.

Preparation.—A detailed account of the process of ether manufacture in this country will be found in Squibb's *Ephemeris*, vol. ii. 590, *et seq.* In outline it may be stated as follows: A mixture of alcohol and sulphuric acid is heated in a suitable still to about 130° C. (266° F.), and when the distillation of ether has begun a continuous supply of fresh alcohol is turned into the still, and so regulated as to keep the mixture at a constant quantity and temperature. The vapors are passed through two purifiers, the first containing a solution of potassium hydroxide, for the purpose of thoroughly washing the vapors in alkaline liquid; the second purifier is provided with a bed of pebble-stones, and here the alcohol and other vapors having a higher boiling-point than ether are condensed and removed. In order that no ether may be lost, both purifiers are kept heated, and the purified ether vapor is finally condensed in a large worm surrounded by water. The theoretical yield of absolute ether is never wholly obtained, and the quantity will vary with the care and attention bestowed. It is important that the temperature be carefully kept between 130° and 138° C. (266° and 280° F.); if it fall below 130° C., an excess of alcohol in the still causes other products to be formed. Since in the formation of ether sulphuric acid is continually regenerated, its power of etherification is theoretically unlimited; but in practice it will be found that the impurities in the alcohol will set a limit, and gradually the acid becomes dark and tarry, and the mixture in the still liable to frothing. According to Squibb, a charge of 360 pounds of sulphuric acid will etherify about 120 barrels of alcohol, provided the latter be clean and of good quality.

The reaction occurring may be illustrated thus: $C_2H_5OH + H_2SO_4 = C_2H_5HSO_4$ (ethylsulphuric acid) $+ H_2O$; then $C_2H_5HSO_4 + C_2H_5OH = (C_2H_5)_2O$ (ether) $+ H_2SO_4$. While the apparent result of the entire reaction consists in the abstraction of 1 molecule of water from 2 molecules of alcohol, the remaining elements forming 1 molecule of ether, other decomposition-products are also obtained, and these it is designed to remove by washing the vapor in warm solution of potassium hydroxide.

The U. S. Pharmacopœia recognizes but one variety of ether, containing about 96 per cent. by weight of absolute ether and about 4 per cent. of alcohol containing a little water; such a preparation has a specific gravity of 0.725–0.728 at 15° C. (59° F.) or 0.716–0.717 at 25° C. (77° F.). The present official ether was formerly known in the Pharmacopœia as *æther fortior*, and is still at times met with under that name. A weaker preparation, containing about 74 per cent. of absolute ether and 26 per cent. of alcohol and water, is sometimes offered as ether, U. S. P. 1880. It has a specific gravity of about 0.750 at 15° C. (59° F.), and should not be confounded with the present official ether. Some manufacturers offer but one article of U. S. P. ether, while others specially designate that intended for anæsthesia. The commercial varieties of "washed" and "concentrated" ether should not be employed for medicinal purposes, as their composition and purity are not stated. The British Pharmacopœia recognizes both Ether and Purified Ether (Æther Purificatus). The former contains not less than 92 per cent. of absolute ether and has the specific gravity 0.735; purified ether, which should have a specific gravity between 0.720 and 0.722, is made by washing ether with water to remove most of the alcohol, and rectifying over calcium chloride and recently burned lime. While the German Pharmacopœia recognizes only ether having the specific gravity 0.720 at 15° C. (59° F.), it makes a distinction between ether and ether for anæsthesia, by directing greater rigidity in the tests to be applied to the latter.

Properties.—Absolute ether is a colorless, very limpid, not solidifiable liquid, of a strong refractive power and having a specific gravity 0.710 at 20° C. (68° F.), Richter, to 0.712 at 25° C. (77° F.), Gay-Lussac, of 0.7188 at 15° C. (59° F.), Squibb. It has a peculiar penetrating odor and a sweetish pungent taste. It boils at 34° to 35° C. (93° to 95° F.), the vapors having a specific gravity of 2.58, and volatilizes very rapidly at ordinary temperature, thereby producing a considerable diminution of temperature. It is easily ignited, and burns with a bright flame, yielding water and carbon dioxide. Its vapor, mixed with a large quantity of air, if ignited, explodes with great violence. In consequence of this property and of the great density of its vapor great care should be exercised in handling ether or manipulating with it in the vicinity of a flame. It dissolves phosphorus, sulphur, iodine, bromine, some metallic sulphides, chlorides, bromides, and iodides, bromoform, chloroform, alcohols, benzene, benzin, fats, volatile oils, many resins, most alkaloids, and some organic acids. When shaken with an equal bulk of water, absolute ether loses one-fourteenth of its volume, which is dissolved by the water, a little of this liquid being dissolved by the ether (Boullay). The presence of water and alcohol is detected by mixing the ether with an equal bulk of carbon disulphide, which should result in a perfectly clear liquid. Aniline-violet is insoluble in absolute ether, but in the presence of 1 per cent. of alcohol colors the liquid distinctly (Stefanelli, 1875).

Official ether boils at about 35° C. (95° F.), U. S., P. G., below 40.5° C. (105° F.), and purified ether not under 34.5° C. (91.4° F.), Br. It is soluble in about 10 volumes of water at 25° C. (77° F.), U. S., and is miscible in all proportions with alcohol, chloroform, benzene, petroleum benzin, fixed and volatile oils.

Tests.—The pharmacopœias prescribe the following tests for the purity of ether: It should have no action on moistened pale-blue litmus-paper and leave no fixed residue upon evaporation. Ether shaken occasionally within one hour with one-tenth its volume of normal potassium hydroxide solution should not develop any color, showing the absence of aldehyde, etc. (U. S.). If 1 Cc. of 10 per cent. potassium iodide solution be frequently shaken with 10 Cc. of ether in a completely filled glass-stoppered vial and protected against light, no coloration should occur in one-half hour; for ether intended for anæsthesia the time is extended to 3 hours (absence of hydrogen peroxide).—P. G. If 100 volumes of ether be agitated with an equal volume of water, at least 90 volumes should separate (absence of excess of alcohol). Ether should dissolve without coloration when added drop by drop to sulphuric acid kept cool during the test (absence of organic impurities). Purified ether should dissolve in an equal volume of carbon disulphide (absence of excess of water); when shaken with half its volume of a dilute solution of potassium dichromate acidulated with sulphuric acid, and set aside, the supernatant liquid should not have a blue color (absence of hydrogen peroxide).—Br. An undue amount of water or alcohol may be detected by shaking 20 Cc. of ether in a graduated tube with 20 Cc. of water previously saturated with ether; upon separation the ethereal layer should not measure less than 19.8 Cc. (U. S.). If 10 Cc. of ether be poured in portions upon clean odorless blotting-paper, and allowed to evaporate spontaneously, no foreign odor should become perceptible when the last traces of ether leave the paper (U. S.).

Pharmaceutical Preparations.—Spirit of Ether, U. S.; Compound Spirit of Ether, U. S.

Action and Uses.—When locally applied, ether produces a cooling sensation, which is due to its rapid evaporation. Advantage has been taken of this fact to produce freezing of the tissues and local anæsthesia when minor surgical operations are to be performed. When administered by the mouth, it has at first a sweetish and afterward a burning, pungent taste. It first causes a burning, and afterward a cooling sensation in the stomach, which rapidly extends over the entire body. The heart and vasomotor system are stimulated, respiration is quickened, the face becomes flushed, a sensation of warmth is felt over the surface of the body, and diaphoresis frequently follows. The mind is powerfully stimulated, ideas follow one another in rapid succession, and the cerebral phenomena produced by alcohol are apparent. These effects are fleeting, and in a short time a feeling of general contentment, mental quiet, and sleep succeed them. When given hypodermically, ether acts more rapidly and more powerfully than when taken by the stomach, but otherwise its general effects are the same. Inhalations of ether vapor at first irritate the mucous membrane of the respiratory tract, and at times cause a temporary arrest of respiration. The face becomes suffused, the conjunctiva injected, and the individual struggles in an attempt to remove the inhaler and obtain fresh air. The primary stage of struggling is rapidly succeeded by one of quiet, during which period the pulse is rapid, full, and strong, and the respiration is accelerated, but the breathing is deep and regular and the reflexes are intact. In a short time the stage of excitement or a second period of struggling occurs. This period varies greatly with the individual; in some cases there may be merely a slight movement of the fingers or hands, but in others violent struggling may ensue. Patients under its influence display various traits and effects, and cursing, screaming, laughing, crying, or praying frequently occur. Following this is the stage of anæsthesia, during which sensation to pain and reflex action are abolished, and if the drug is sufficiently pushed complete muscular relaxation occurs. The pupils are usually normal, and, unless the patient is profoundly anæsthetized, should react to light. Ether first depresses the intellectual centers of the brain, then the sensory tracts of the cord, the motor tracts of the cord, the sensory centers of the medulla, and finally the respiratory center, causing death by respiratory failure. It exerts no effect upon the nerve-trunks unless it is directly applied. Ether is a rapidly acting, diffusible, and consequently a fleeting cardiac stimulant. It also stimulates the vasomotor center; blood-pressure is increased and the pulse becomes more rapid and forcible. In overdoses it acts as a cardiac depressant. It has been shown by J. Chalmers Da Costa that the inhalation of ether decreases both the number of red blood-corpuscles and the hæmoglobin. While ordinary amounts of this drug stimulate the respiratory center, overdoses paralyze it, and so cause death. The primary arrest of respiration which is seen during its early administration is due to irritation of both the vagal and trifacial nerves. Prolonged etherization very materially lowers the bodily heat; this is due to the rapid evaporation of the drug from the lungs and to the depression which it produces upon the nervous system. Ether is eliminated by the lungs and kidneys. It is a renal irritant, and may cause an acute nephritis and at times complete suppression of the urine.

Large quantities of mucus sometimes collect in the bronchial tubes during etherization, but this may usually be overcome by the hypodermic administration of a full dose of atropine. Accidents occurring during the administration of ether should be treated by the removal of the drug and the institution of artificial respiration. Hypodermic injections of strychnine, atropine, and digitalis should also be given. If the face is pallid, it indicates cardiac embarrassment and the head and shoulders should be lowered. If the face becomes suffused and cyanotic, it indicates respiratory difficulty, and this position should not be resorted to. Hypodermic injections of alcohol or ether are of little value in these conditions, provided the cause is the direct result of an overdose of the anæsthetic; but they may be successfully administered when the respiratory failure is due to asphyxia resulting from mechanical interference with free breathing.

Because of the vomiting which it produces, ether is contraindicated in gastritis and peritonitis. It should not be employed when bronchitis, catarrhal pneumonia, or acute nephritis is present. It is well to substitute chloroform for it in aneurism or in the presence of marked vascular atheroma.

Locally ether may be employed in an atomizer for producing local anæsthesia.

Internally by the stomach it is of service in the flatulent colic of adults and children. It may be given also either by the mouth or hypodermic needle in the treatment of uræmia, especially if the cardiac or respiratory complications are marked. Ether may be employed with advantage as a rapidly acting cardiac and respiratory stimulant in cases of collapse. By inhalation it is employed to produce surgical anæsthesia, to cause muscular relaxation in hernia. When a moderate amount is inhaled, it frequently relieves spasmodic hiccough, local muscular spasms, and the pain of angina pectoris.

The dose of ether is from 30 minims to 2 fluidrachms (2–8 Cc.), given either in ice water or preferably in capsules. The spirit of ether and compound spirit of ether are also given in the same dose.

Allied Compounds.—ÆTHER FORMICUS.—*Formic ether, Ethyl formate*, E.; *Ameisenäther*, G. $C_2H_5CHO_2$ or $HCOOC_2H_5$.—It was first obtained by Bucholz (1782), and may be prepared by distilling a mixture of 8 parts of dry sodium formate, 7 parts of alcohol (88 per cent.), and 11 parts of strong sulphuric acid. Usually sufficient heat is produced upon addition of the acid to volatilize the ester, and the distillate, if acid, is shaken with sodium carbonate solution, and finally rectified from calcium chloride. Formic ether is a thin colorless, inflammable liquid, of strong agreeable odor and pungent taste. Its specific gravity is 0.918 at 17° C. (62.8° F.) and its boiling-point 55° C. (131° F.); it is soluble in 9 parts of water and in all proportions in alcohol, ether, fixed and volatile oils. When inhaled, it lowers the temperature as much as 3.5° C. (6.3° F.), inducing signs of asphyxia, and causes muscular relaxation and anæsthesia. In man 6 or 8 Gm. occasion no other symptoms than drowsiness.

ÆTHER METHYLICUS.—*Methyl ether, Methyl oxide*, E.; *Methyläther, Holzäther*, G. $(CH_3)_2O$.—It was discovered by Dumas and Peligot (1835), and is prepared by distilling a mixture of 1 part of methyl alcohol and 4 parts of sulphuric acid; the vapors are washed by passing through potassium hydroxide solution or milk of lime, whereby carbon and sulphur dioxides, as well as methyl sulphuric ether, are removed. The latter body, having a garlic-like odor, is decomposed. Methyl ether is a colorless, inflammable gas, heavier than air, of an ethereal odor and aromatic taste. At —36° C. (—32.8° F.) it forms a colorless liquid which boils at —21° C. (—5.8° F.). Water dissolves 35 volumes of the gas, acquiring its odor and taste, and evolving it again at a moderate heat. It is more soluble in sulphuric acid, and still more freely in alcohol, methyl alcohol, and ether. A solution in the latter liquid saturated at 0° C. (32° F.) has been recommended by Dr. B. W. Richardson under the name of methyl-ethyl ether (see below) as a safe, rapidly acting anæsthetic; it should be kept in well-corked bottles in a cool place.

ÆTHER METHYL-ETHYLICUS.—*Methyl-ethyl ether, Methyl-ethyl oxide*, E.; *Methylaethyläther*, G. $CH_3C_2H_5O$.—This compound, which must not be confounded with the solution of Dr. Richardson mentioned above, was first obtained by Williamson by the action of ethyl iodide upon sodium methylate, and this has proved to be the best method since. The two substances are caused to react in a retort, and the vapors made to pass through a weak sodium hydroxide solution cooled to 15° C. (59° F.), whereby volatile by-products are removed, the methyl-ethyl ether being finally condensed in a well-cooled receiver. It is a colorless liquid, very inflammable, of peculiar characteristic odor, boiling at 11° C. (51.8° F.). Its use as an anæsthetic has been very limited.

ÆTHER ACETICUS, *U. S., Br., P. G.*—Acetic Ether.

Naphtha aceti.—Ethyl acetate, E.; *Ether acétique. Acétate d'éthyle*, Fr.; *Essigäther, Essignaphtha*, G.; *Etere acetico*, It.

Formula, $C_2H_5C_2H_3O_2$ or $CH_3COOC_2H_5$. Molecular weight, 87.40.

Preparation.—The following method, recommended by Hager, yields very satisfactory results, and is admirably adapted to the manufacture of acetic ether in small lots: 63 parts by weight of alcohol (specific gravity 0.820) are carefully mixed with 109 parts by weight of 94 per cent. sulphuric acid, and the mixture set aside for a day or two in a well-closed flask, so that ethyl-sulphuric acid may be formed; having prepared anhydrous sodium acetate by heating at 130° C. (266° F.) to constant weight, 82 parts of the powdered acetate are put into a retort and the acid alcohol mixture carefully added. The retort is heated on a water-bath, and the vapors are condensed in a well-cooled receiver as long as reaction continues brisk; the final distillate is collected separately, as it is apt to contain more acetic acid. The process involves the following reactions: (1) $C_2H_5OH + H_2SO_4 = C_2H_5HSO_4$ (ethyl-sulphuric acid) $+ H_2O$; (2) $C_2H_5HSO_4 + NaC_2H_3O_2 = C_2H_5C_2H_3O_2$ (ethyl acetate) $+ NaHSO_4$.

Crude acetic ether usually contains acetic acid, alcohol, and water, and to remove these it is first well shaken with one-third of its volume of an aqueous solution containing 20 per cent. sodium chloride and 2 per cent. sodium carbonate; caustic alkalies or milk

of lime are inadmissible. The washing is repeated two or three times, and the ether is then freed from water by shaking with freshly ignited potassium carbonate, and finally is distilled; calcium chloride is not suitable for dehydration, as it is apt to combine chemically with the acetic ether.

The U. S. Pharmacopœia defines acetic ether to be a liquid containing about 90 per cent. by weight of ethyl acetate and 10 per cent. of alcohol, mixed with a little water.

Properties and Tests.—Acetic ether is a colorless, limpid, volatile liquid having an agreeable, refreshing, ethereal, and somewhat acetous odor and taste. The densities given by the pharmacopœias are: 0.883 to 0.885 at 25° C. (77° F.), U. S., 0.900 to 0.904, P. G., and 0.900 to 0.905, Br. The density is no evidence of purity, since acetic ether dissolves ether, alcohol, and chloroform in all proportions, and at 15° C. (59° F.) one-twenty-fourth of its volume of water. It is also soluble in water, requiring of that menstruum at 0° C. (32° F.) 8 volumes, and at 15° C. (59° F.) 9 volumes, or 10 parts by weight (Clark), not less than 10 parts, Br.; about 7 parts at 25° C. (77° F.), U. S. It boils between 74° and 76° C. (165° and 168.8° F.), P. G.; at 73.9° to 77.8° C. (165°–172° F.), Br., at about 72° C. (161.6° F.), U. S. It is very inflammable, though less so than ether, and burns with a yellowish-white flame, giving off vapors having the odor of acetic acid. It has a neutral reaction to test-paper, but if kept in contact with the air, and particularly in the presence of water, free acetic acid is formed. Solutions of potassium, sodium, and other hydroxides decompose it gradually, if heated, into acetic acid and alcohol; but metallic sodium does not act upon acetic ether in the cold except in the presence of water or alcohol (Wanklyn, Ladenburg). It dissolves a little phosphorus and sulphur, and is a good solvent for volatile and fixed oils, many resins, cantharidin, and other organic compounds.

The *purity* of acetic ether is determined by its neutral reaction, its specific gravity, its volatility without residue, and its behavior to water; when 10 Cc. of it are agitated with an equal volume of water, just previously saturated with acetic ether, in a graduated tube, the ethereal layer, after its separation, should measure not less than 9 Cc. If a portion be allowed to evaporate spontaneously from clean, odorless blotting-paper, the final odor should not resemble that of pineapple (absence of butyl and amyl derivatives). —U. S. If acetic ether is allowed to flow carefully upon an equal volume of concentrated sulphuric acid, no dark color should be formed at the line of contact of the two liquids.—U. S., P. G.

Action and Uses.—Acetic ether closely resembles sulphuric ether in its action on the system, but being less volatile than the latter it is absorbed more slowly, and is consequently not so prompt in producing anæsthesia. The drug is also eliminated with less rapidity than is sulphuric ether, hence it is not sufficiently fleeting in its effect to lend itself as a useful anæsthetic. The inhalation of small quantities may be useful in bronchial and laryngeal irritation, and in nervous cough and syncope. Internally it is stimulant and antispasmodic, and small doses have been employed in flatulent colic. Externally it is an irritant, and may be employed as an embrocation in the treatment of muscular rheumatism and in other conditions in which liniments are commonly recommended.

The dose is from 15 to 30 minims (1–2 Cc.), well diluted.

ÆTHYLENI BICHLORIDUM.—Ethylene Bichloride.

Æthylenum chloratum, Elaylum chloratum, Liquor Hollandicus.—Ethene chloride, Dutch liquid, E.; *Liqueur des Hollandais, Huile du gas olefiant*, Fr.; *Æthylenchlorid, Elaylchlorid*, G.

Formula, $C_2H_4Cl_2$ or $CH_2Cl.CH_2Cl$. Molecular weight, 98.18.

Preparation.—Ethylene or olefiant gas and Dutch liquid were discovered by Dieman, Troostwyk, Bondt, and Lauwernburgh (1795). The latter is produced on bringing the former in contact with chlorine gas. 1 part of strong alcohol is mixed with 3 or 4 parts of sulphuric acid and sufficient sand to form a thick mixture, which is heated, and the gas passed successively through sulphuric acid, solution of potassium hydroxide, and sulphuric acid, whereby it is deprived of alcohol, ether, and sulphur and carbon dioxides. The gas thus purified is conducted into a retort containing a mixture of 2 parts of manganese dioxide, 3 of common salt, 4 of water, and 5 of sulphuric acid.

The retort is at first very moderately warmed, and afterward heated, when the liquid distils. The distillate is washed with water and rectified over calcium chloride.

Properties.—It is a colorless, thin, oily liquid, having an ethereal odor resembling that of chloroform, and a sweetish, ethereal taste; it has the specific gravity 1.28 at 0° C. (32° F.) or 1.254 at 15° C. (59° F.), is sparingly soluble in water and freely soluble in alcohol and ether. It is inflammable, and burns with a yellowish flame having a green border, and giving off vapors containing hydrochloric acid. When agitated with water the latter does not acquire an acid reaction to litmus-paper, and when agitated with sulphuric acid the mixture is not blackened. On being mixed with alcoholic solution of potassium hydroxide, water and potassium chloride are formed, and gaseous *chlorethyline*, CH_2CHCl, is given off at a moderate temperature; this gas condenses at —18° C. (—4° F.).

Action and Uses.—Considerable difference of opinion as to its value exists among the various authors who have experimented with ethylene bichloride. This is probably due to the fact that in some cases an impure article was employed. However, even when the pure drug is used, all are not agreed upon its efficacy as a practical anæsthetic. Simpson claims it to be entirely too irritating to the mucous membranes, and that very few can inhale it sufficiently long to cause anæsthesia. Mr. Nunnelly has employed it in many cases, and he and Dr. Reichert both state that while it does irritate the respiratory tract, its effects are no more marked than those of ether, and that it acts as a cardiovascular depressant, causing a gradual decrease in blood-pressure, although its effect is less marked than that of chloroform. The drug causes less excitement during the early stages of its administration than does ether, and in overdose produces death by centric respiratory paralysis. It has been applied as a local anæsthetic for the relief of neuralgia and other limited painful areas, but because of its high price the drug is rarely employed.

ÆTHYLIS BROMIDUM.—Ethyl Bromide.

Æther bromatus, P. G.; *Monobromethane, Hydrobromic ether*, E.; *Bromure d'éthyle, Ether hydrobromique (bromhydrique)*, Fr.; *Æthylbromid, Bromäthyl, Bromwasserstoffäther*, G.

Formula, C_2H_5Br. Molecular weight, 108.12.

Preparation.—Serullas (1827), the discoverer of this ether, recommended its preparation by the action of bromine upon alcohol in the presence of phosphorus. Personne (1861) replaced the latter by amorphous phosphorus. The German Pharmacopœia gives the following directions for its manufacture: To a well-cooled mixture of 12 parts of sulphuric acid and 7 parts of alcohol (specific gravity 0.816), 12 parts of potassium bromide in powder-form are gradually added, and the mixture then distilled on a sand-bath; the distillate is well washed by agitation, first with an equal volume of sulphuric acid and then with a 5 per cent. solution of potassium carbonate; finally, it is dehydrated with calcium chloride and redistilled on a water-bath. This process involves a double reaction: first, the formation of ethylsulphuric acid, $C_2H_5OH + H_2SO_4 = C_2H_5HSO_4 + H_2O$; and secondly, the formation of ethyl bromide, $C_2H_5HSO_4 + KBr = C_2H_5Br + KHSO_4$.

Properties.—Ethyl bromide is a colorless, highly refractive, very volatile liquid, of a strong ethereal odor and a sweetish and warm taste. It has the density 1.453–1.457 at 15° C. (59° F.), boils at 38°–40° C. (100.4°–104° F.), burns with some difficulty with a green non-sooty flame, is sparingly soluble in water, and dissolves in all proportions in alcohol and ether. It is easily decomposed by light and air, turning brown, and then containing hydrobromic acid and free bromine. The presence of 1 per cent. of alcohol or 3 per cent. of ether renders the liquid more stable.

Tests.—Ethyl bromide should have a neutral reaction, and if shaken with an equal volume of pure concentrated sulphuric acid no color should be produced within one hour (absence of ethylene and amyl compounds). If shaken with an equal volume (5 Cc.) of water for a few seconds, a portion (2.5 Cc.) of the latter, removed with a pipette, should remain clear for at least 5 minutes upon addition of 1 drop of silver nitrate test-solution, showing absence of hydrobromic acid.

This preparation should not be confounded with *ethylene bromide*, $C_2H_4Br_2$, a faintly brown-colored liquid, with chloroform-like odor and a sweet taste, followed by a burning sensation. Its specific gravity at 21° C. (69.8° F.) is 2.163 and boiling-point at 131° C.

(267.8° F.); at 0° C. (32° F.) it solidifies to a snow-white crystalline mass. When inhaled, marked poisonous effects have been produced.

Action and Uses.—Ethyl bromide is commonly employed as an anæsthetic, and the advantages claimed for it are its agreeable odor, slight irritant properties, and great rapidity of action, with sudden return to consciousness after withdrawal of the drug. It is also stated that this compound is less liable to cause an outpouring of mucus, salivation, headache, and vomiting than the older anæsthetics. At present, pure ethyl bromide is considered a safe anæsthetic, and it is probable that the many fatalities resulting from its employment were due to the administration of an impure article. It has been suggested that the decomposition of the drug may also have been the cause of some fatal issues. Like other anæsthetics, it depresses the central nervous system. It has only a slight depressing effect upon the circulation and respiration when given in moderate amount. The pulse is slowed by stimulation of the vagi, and arterial tension is slightly lowered. Excessive quantities cause death by respiratory failure. Ethyl bromide is rapidly eliminated by the lungs and kidneys. When moderate amounts are inhaled, the face becomes suffused, the pupils dilated, and the pulse somewhat slower. Muscular relaxation takes place and the respiration is slightly impeded. Sudden death due to respiratory paralysis occasionally occurs from its administration, and in other cases death has taken place in from 8 hours to 3 days after its employment. Occasionally syncope, nervous twitchings, or tetanic convulsions have resulted from its use, but they are usually of short duration, and little importance may be attached to them. The treatment of accidents occurring during the administration of this drug consists first in its removal, and second in the prompt institution of artificial respiration. The administration of respiratory stimulants, such as alcohol, strychnine, and atropine, is also to be recommended.

Ethyl bromide has been employed in an atomizer as a local anæsthetic, but ethyl chloride has now almost supplanted it for this purpose. As a general anæsthetic it is to be recommended in all minor surgical operations, such as the opening of boils or abscesses. E. E. Montgomery recommends it highly as an anæsthetic in minor gynæcological operations and in labor; especially in the latter condition, as it is less apt to cause uterine relaxation and post-partum hemorrhage.

Ethyl bromide should be given in as concentrated a form as possible. The cloth or inhaler containing it should be so placed that little or no air is inhaled during its administration. As a general anæsthetic, from 45 minims to 3 fluidrachms (3–12 Cc.) are usually required, and when major surgical operations are to be performed, it is to be followed by ether or chloroform. Internally it has been recommended as a soporific in doses of from 5 to 20 minims (0.30–1.30 Cc.), largely diluted with ice water.

ÆTHYLIS CARBAMAS, *U. S.*—Ethyl Carbamate.

Ethyl urethane, Urethane, E.; *Uréthane,* Fr.; *Carbaminsäure-Æthylester, Æthylurethan, Urethan,* G.

Formula, $C_2H_5CH_2NO_2$ or $CO.NH_2.OC_2H_5$. Molecular weight, 88.42.

An ester of carbamic acid obtained by the reaction of alcohol upon urea or one of its salts. It should be kept in well-stoppered bottles.—U. S.

In chemistry the general term "urethane" is applied to all ethers of carbamic acid, which acid, however, has thus far never been isolated, and is only known in combination: its most familiar compound is ammonium carbamate, $NH_4NH_2CO_2$, one of the constituents of official ammonium carbonate. If the formula for carbamic acid is assumed to be HNH_2CO_2, then the formation of all urethanes may be explained by the substitution of a univalent radical for the 1 atom of displaceable hydrogen, which may be brought about in various ways.

Preparation.—Ethyl carbamate may be prepared by allowing an excess of alcohol to react with urea nitrate at a temperature of about 125° C. (257° F.) in a sealed tube for several hours. The resulting mass, when cool, becomes crystalline, and is then dissolved in just sufficient water, the solution being subsequently repeatedly shaken out with ether. After recovery of the ether, the residue is distilled and recrystallized from water. The reaction involved is shown by the following equation: $(NH_2)_2COHNO_3 + C_2H_5OH = CO.NH_2.OC_2H_5 + NH_4NO_3$. It may also be obtained by the action of

ammonia on ethyl carbonate or chlorocarbonate, or by direct union of cyanic acid with ethyl alcohol.

Properties and Tests.—Ethyl carbamate occurs in columnar colorless crystals or scales, odorless, and having a cooling saline taste. It is soluble at 25° C. (77° F.) in less than its own weight of water, 0.6 part of alcohol, 1 part of ether, 1.3 parts of chloroform, and 3 parts of glycerin. When heated to 47.5°–50° C. (117.5°–122° F.) it melts, and at a higher temperature is decomposed, burning without leaving a weighable residue. If 1 Gm. of ethyl carbamate be added to 5 Gm. of sulphuric acid and gently heated, it is decomposed with evolution of carbon dioxide, while alcohol and acid ammonium sulphate remain in solution. If 1 Gm. of ethyl carbamate be heated with 5 Cc. of concentrated potassium hydroxide solution, ammonia gas is given off, recognizable by the usual tests. If 0.5 Gm. of ethyl carbamate be dissolved in 5 Cc. of water, and warmed with 1 Gm. of dry sodium carbonate and 0.01 Gm. of iodine, yellow crystals of iodoform separate on cooling. If 6 Gm. of ethyl carbamate be dissolved in 6 Cc. of water, and the solution be divided into 3 equal parts, the addition severally of 5 Cc. of nitric acid, of mercuric nitrate test-solution, or of oxalic acid test-solution should not produce a white precipitate (distinction from, and absence of, urea or carbamide).—U. S.

Action and Uses.—Ethyl carbamate is a hypnotic resembling paraldehyde in its physiological action and is devoid of the unpleasant odor and taste of the latter drug. It exercises practically no direct analgesic influence. Reports concerning the value of the drug are very contradictory, and it is generally considered an unreliable hypnotic. In those instances in which it is effective, the sleep produced is quiet and tranquil, usually unattended by depression or unpleasant after-effects. Overdoses cause distinct depression of the spinal cord, heart, and respiration. Death from a fatal quantity is due to asphyxia. Urethane may be employed in nervous or functional insomnia, as in that due to mental or physical depression, chronic alcoholism, and insanity. A case of traumatic tetanus in a boy of fifteen years is said to have been cured by 4-grain doses of urethane every 2 hours. The dose is from 15 to 45 grains (1–3 Gm.), in powder, capsule, or solution. It has been administered hypodermically in about one-fourth the dose given by the mouth.

Allied Compounds.—EUPHORIN. *Ethyl phenylcarbamate. Phenylurethane,* $C_2H_5NHC_6H_5CO_2$ or $CO(NHC_6H_5)(OC_2H_5)$.—This compound is obtained by the interaction of aniline and ethyl chloroformate, and is purified by recrystallization from diluted alcohol. It is a white or colorless crystalline powder, of faint aromatic odor and slight clove-like after-taste. Euphorin is sparingly soluble in cold, but more readily in hot water, and soluble in alcohol, ether, and hydroalcoholic mixtures, such as wines, etc. The compound melts between 49° and 50° C. (120.2° and 122° F.), and dissolves without color in cold sulphuric acid. Euphorin possesses analgesic, antipyretic, and antirheumatic properties given in doses of from 2 to 8 grains (0.10–0.50 Gm.). It is also used as an antiseptic, applied in powder or made into an ointment, in the treatment of ulcers and other cutaneous lesions.

NEURODIN. *Acetyloxyphenylurethane,* $C_6H_4(CO_2CH_3)NH.CO_2C_2H_5$.—Colorless, odorless crystals, melting at 87° C. (188.6° F.), and soluble in 1400 parts of cold or 140 parts of hot water. It is obtained by acetylating paraoxyphenylurethane, an intermediate product of the action of ethyl chloroformate upon para-amidophenol. Neurodin is said to possess antipyretic as well as antineuralgic properties, and is given in doses of from 7½ to 22½ grains (0.5–1.5 Gm.).

THERMODIN. *Acetylethoxyphenylurethane. Phenacetin-urethane,* $C_6H_4(OC_2H_5)N(COCH_3)CO_2C_2H_5$.—Colorless, odorless, and tasteless needle-shaped crystals, melting at about 87° C. (188.6° F.), and soluble in 2600 parts of cold or 450 of boiling water. It is obtained by acetylation of paraethoxyphenylurethane, an intermediate product of the action of ethyl chlorocarbonate upon paraphenetidin. Used like the preceding compound in doses of from 7½ to 15 grains (0.5–1 Gm.).

ÆTHYLIS CHLORIDUM, *U. S.*—Ethyl Chloride.

Æthylum chloratum, Æther chloratus.—Monochlorethane, Hydrochloric ether, E.; *Chlorure d'éthyle, Ether hydrochlorique,* Fr.; *Æthylchlorid, Chloræthyl, Chlorwasserstoffäther,* G.

The names *Chelen* and *Kelen* are used for ethyl chloride in some parts of Europe.

Formula, C_2H_5Cl. Molecular weight, 64.00.

A haloid derivative, prepared by the action of hydrochloric acid gas upon absolute alcohol. On account of its extreme volatility it should be preserved in hermetically sealed glass tubes, and kept in a cool place remote from lights or fire.—U. S.

Preparation.—Ethyl chloride is obtained by passing dry hydrochloric acid gas into cold absolute alcohol, distilling at a very moderate heat, washing the distillate with water and a weak alkaline solution, and rectifying. It is said also to be made on a large scale by heating a mixture of alcohol and concentrated hydrochloric acid for some time under increased pressure (40 atmospheres) at a temperature of 150° C. (302° F.), and then distilling the resulting product. The ethyl chloride vapors are passed through water warmed to 25° C. (77° F.), then dried by passing over calcium chloride, and finally condensed in well-cooled vessels. The reaction between alcohol and hydrochloric acid is shown by the following equation: $C_2H_5OH + HCl = C_2H_5Cl + H_2O$.

Properties and Tests.—"Ethyl chloride is a colorless, mobile, very volatile liquid, having a characteristic, rather agreeable odor, and a burning taste. Its specific gravity is 0.918 at 8° C. (46.4° F.). It is slightly soluble in water, readily soluble in alcohol. Ethyl chloride boils at a temperature of 12.5° to 13° C. (54.5–55.4 F.), and at its ignition temperature burns with a smoky, green-edged flame, with the production of gaseous hydrochloric acid. When liberated, at ordinary room-temperature, from its sealed glass tube, ethyl chloride vaporizes at once; the gas is very inflammable, and consequently it should not be used in proximity to a gas-flame or fire."—U. S. If chlorine be allowed to act on ethyl chloride, ethylidene chloride, also known as monochlorinated hydrochloric ether, $C_2H_4Cl_2$, is produced, which is isomeric with ethylene bichloride and resembles the same in odor, but differs from it in density (1.198) and boiling-point (57.5° C.). "If 10 Cc. of ethyl chloride, while cold, be dissolved in alcohol, and a few drops of silver nitrate test-solution be added, no turbidity should be produced (absence of hydrochloric acid). If 10 Cc. of ethyl chloride be agitated with 10 Cc. of cold water, and the supernatant stratum of ethyl chloride be evaporated spontaneously, and if a few drops of potassium dichromate test-solution be added to the remaining aqueous liquid, followed by some diluted sulphuric acid, and the mixture boiled, no odor of aldehyde should be devoloped, and a greenish or purplish color should not be produced in the liquid (absence of alcohol). On allowing ethyl chloride to evaporate from clean, odorless blotting-paper which has been saturated with it, no unpleasant odor should remain upon the paper (absence of sulphur compounds, etc.)."—U. S.

Action and Uses.—Ethyl chloride is employed in medicine for two purposes: as a local anæsthetic and as a general anæsthetic. When employed as a local anæsthetic, it is sprayed upon the part which is to be anæsthetized, being driven, from a glass tube which contains it, through a fine opening at the end of the tube, the heat of the hand causing sufficient vaporization to produce pressure and to cause free escape of the liquid. Its rapid evaporation as it strikes the skin produces a momentary redness, followed by the sudden appearance of a white spot, which is due to freezing taking place, and, while this lasts, the incision is made. Certain manufacturers combine with ethyl chloride various drugs like the oil of mustard, the active principle of capsicum, and menthol, all of which are designed to aid in producing the local anæsthesia or to cause a therapeutic effect in addition to that produced by the freezing of the part. This local freezing is useful not only for the production of anæsthesia in small operations, but also for the benumbing of painful nerves, as in cases of supraorbital neuralgia. Ethyl chloride has more recently been advocated by some persons as a general anæsthetic. When given by inhalation, it is not suited to prolonged operations, because its action is fleeting and not profound. When it is inhaled, the reflexes are usually entirely abolished, but muscular rigidity is not always overcome. Its vapor should be given in concentrated form. A useful way to give it is to place a large funnel over the patient's nose and mouth, to close the space between the edge of the funnel and the angles of the mouth by the hands or by a napkin, and then to spray the drug into the small end of the funnel, a little cotton being placed loosely in the funnel to collect the liquid and to permit its rapid volatilization. Given in this form, so that the patient inhales the concentrated vapor, moderate anæsthesia is quickly produced. Many practitioners prefer using specially prepared inhalers for the administration of this anæsthetic. Given by inhalation, the drug has the advantage that it is more pleasant in odor than sulphuric ether.

ÆTHYLIS IODIDUM.—Ethyl Iodide.

Hydriodic ether, E.; *Iodure d'éthyle, Ether hydriodique*, Fr.; *Jodäthyl, Jodwasserstoffäther*, G.

Formula, C_2H_5I. Molecular weight 154.72.

Preparation.—This compound was prepared by its discoverer, Gay-Lussac (1815), by distilling a mixture of absolute alcohol and concentrated hydriodic acid, and separating the ether from the distillate by means of water. Much better results are obtained by distilling a mixture of alcohol, phosphorus, and iodine, as proposed by Serullas (1827); and the substitution of amorphous for ordinary phosphorus, first used by Personne (1861), affords still greater advantages. The method now followed consists in adding 40 parts of iodine, in small portions, to a mixture of 60 parts of 95 per cent. alcohol and 5 parts of amorphous phosphorus contained in a retort. The vessel is set aside for 24 hours, and then, after attachment of a Liebig condenser, is heated on a sand-bath to about 80° C. (176° F.). The yellow-colored distillate is shaken with a dilute solution of acid sodium sulphite, after which the supernatant ethereal layer is twice washed with double its volume of water, dehydrated by means of calcium chloride and rectified on a water-bath. The residue in the retort from the first distillation consists of phosphoric acid, the reaction occurring according to the following equation: $5I_2 + P_2 + 10C_2H_5OH$ yields $10C_2H_5I + 2H_3PO_4 + 2H_2O$.

Properties.—Ethyl iodide is a colorless non-inflammable liquid having a peculiar penetrating odor. It is freely soluble in alcohol, nearly insoluble in water, does not react upon litmus, boils near 72° C. (161.6° F.), and has at 15° C. (59° F.) the specific gravity 1.944. Exposed to air and light, it liberates iodine, and is gradually colored red and brown; the presence of metallic mercury, or preferably silver, prevents the coloration but not the decomposition. Iodine is liberated also by chlorine gas, nitric acid, and strong sulphuric acid.

Action and Uses.—Ethyl iodide is said to possess no soporific or anæsthetic properties when employed in moderate amounts. In large quantities, however, it produces anæsthesia. Small quantities when inhaled do not produce irritation of the respiratory tract, but, on the contrary, cause the breathing to become deeper and easier. Hydriodic ether has been recommended for the purpose of bringing the organism rapidly under the influence of iodine in the treatment of pulmonary tuberculosis and chronic bronchitis and chronic laryngitis. As it possesses certain antispasmodic properties, it has been suggested as a remedy in the treatment of spasmodic asthma. The dose for inhalation is from 10 to 15 minims (0.60–1 Cc.) several times daily or as occasion requires. It may be kept in glass pearls, which may be crushed in a handkerchief and inhaled as needed.

AGAR-AGAR.—Vegetable Gelatin; Gelosine.

A gelatin-like substance, extracted in the East Indies from various species of seaweeds. The largest production is in China, but the best product, at least for bacterial purposes, comes from Japan. The complete list of species yielding it is very uncertain, but it appears to come principally from *Eucheuma gelatinum* Agardh., *E. spinosum* Agardh., *Gelidium corneum* Lam., *G. cartilagineum* Gaill., *Gloiopeltis tenax* J. Agardh., *Sphærococcus* (*Plocaria* Montez; *Gracilteria* Greville) *compressus* Agardh., and *S. lichenoides* Agardh. The last-named species is the source of the celebrated Chinese "birds'-nest pudding." Agar-agar is extracted by hot water and dried for commercial purposes in the form of bundles of shreds about 2 feet long or (the Japanese product) in yellowish-white sticks a foot long and an inch wide, or in small cakes or thin sheets.

Agar-agar consists practically of gelose, which dissolves in 500 parts of water and is precipitated in an impure form by alcohol. Its acidulated aqueous solution will not form into a jelly.

Pharmaceutical Uses.—Agar-agar jelly, made by dissolving 1 part of commercial agar powder in 29 parts of water on a water-bath, and adding to the resulting acid solution sodium bicarbonate in the proportion of 1 part to 100 parts by weight, has been suggested for the preparation of suppositories, but experience has shown that it is not

desirable, owing to the fact that the jelly requires for fusion a temperature far above that of the human body; moreover, the suppositories when exposed to air become dry and hard. A thinner jelly, made in the proportion of agar-agar 1 part and water 100 parts, has been used as a vehicle for ointments and dermatologic pastes, for which the advantage is claimed that, upon drying, the resulting film is non-contractile.

Agar-agar has also been proposed as a substitute for sodium stearate in the manufacture of glycerin suppositories, but it has been found to be impossible to make such suppositories stronger than 75 per cent. of glycerin, whereas the official glycerin suppositories contain 90 per cent. (see *Am. Jour. Phar.*, 1895, page 599).

Action and Uses.—Agar-agar is practically never used in medicine. It possesses demulcent and emulsifying properties in common with the other species of algæ. It is principally used at present in bacteriological laboratories as a culture-medium for micro-organisms.

AGARICUS.—Boletus; White or Purging Agaric.

Larch agaric, Male agaric, German tinder, E.; *Lärchenschwamm* G.; *Agaric blanc officinal, Polypore du Méleze,* Fr. Cod.

The dried plant *Polyporus officinalis* Fries (*Boletus laricis* Jacq., *B. purgans* Pers.—Fam. *Polyporei*).

Origin.—This fungus grows on old trunks of the European larch in central and southern Europe, and on *Larix Sibirica* Ledebour, in northern Asia, whence it is brought into commerce. We have also found apparently the same upon *Pinus ponderosa* Dougl. in Arizona, and it is said to come from Central America.

Description.—It is sessile, hoof-shaped or irregularly conical, 10 to 20 Cm. (4 to 8 In.) broad, 5 to 10 Cm. (2 to 4 In.) thick, and sometimes 20 to 30 Cm. (8 to 12 In.) high, externally grayish or yellowish; the hymenium on the lower side is in the form of small yellowish pores. It is collected in autumn and winter, and deprived of the firm outer rind. In commerce it occurs in irregular pieces of the size of the fist, and frequently much larger. It is white, light, somewhat spongy, resinous, very friable, but not readily pulverizable; has a faint odor and a sweetish, afterward acrid and lastingly bitter taste.

Constituents.—Agaricin, the so-called active principle in commerce, is not the *agaracin* of the P. G., which is *agaric* (or *agaricic*) *acid.* It is far better, therefore, to prescribe it under the latter name.

White agaric, when treated with alcohol, yields 4 resinous principles, which are separated during evaporation of the alcohol, when 3 white resins are precipitated, the other, red-colored resin, remaining in solution. The precipitate is collected and treated with alcoholic potassium hydroxide solution, which dissolves only the α resin. The residue, containing the β and the γ resin, is treated with water, when only the former, as potassium salt, is dissolved. This aqueous solution is precipitated with barium chloride, the precipitate collected, dissolved in boiling dilute alcohol, and the resin freed by sulphuric acid. The alcoholic filtrate yields on cooling agaricin, which may be obtained in the crystalline state from 30 per cent. alcohol, which the P. G., however, does not require.

The total amount of resinous matter in agaric is said to reach 79 per cent. (Lloyd). This mixed resin is also used medicinally in doses of 0.015 Gm.

Action and Uses.—Agaricin when applied to abraded surfaces or mucous membranes acts as a distinct counterirritant. Its subcutaneous injection may even produce suppuration. Internally in overdose it is an irritant to the gastro-intestinal mucous membrane, and may cause nausea, vomiting, and purging. It is stated that the drug has a selective action upon the peripheral nerves supplying the sweat-glands, as that secretion is greatly decreased during its administration. Apparently it has no effect upon other secretions. In overdose it may cause depression and dyspnœa. Agaric has been employed in the dose of 5 grains (0.30 Gm.) in the night-sweats of phthisis, but in the writer's experience it has seldom given benefit. As the drug is slowly absorbed, it should be given several hours before the expected sweat.

Agaricin may be given in the dose of 1 or 2 grains (0.06–0.12 Gm.).

Other Species.—P. SUAVEOLENS Fr. (*Boletus salicis, Weidenschwamm*), *P. annosus* Fr. (*Birkenschwamm*), *P. squamosus* Fr., and other species, have apparently a similar composition and similar properties. *P. anthelminthicus* (*Chu-tan* of the Chinese) is used as an

anthelmintic. *P. hirsutus* Fr. (*Borstenlächerschwamm* or *Pugak*), and *P. tinctorius* Quel., yield dye-stuffs.

P. FOMENTARIUS (L.) Fr. (*Surgeons' agaric, Fungus chirurgorum, Oak agaric, Spunk, Punk, Touchwood, Amadou, Agaric du chêne, Wundschwamm, Feuerschwamm, Zünder*) is a very different substance; its uses mechanical. It is collected in central and southern Europe, chiefly from oak and beech, peeled and trimmed down to the cellular tissue, sliced, washed in weak alkali, then in water, beaten, and worked until soft, washed in niter and dried. The slices are then soft and tough, light, elastic and cushion-like, the surface of a light-brown velvety appearance. It is without taste and is inert.

Similar, but harder products are yielded by *P. igniarius* and *P. marginatus* Fries, the former internally rust-brown or dark cinnamon-brown, the latter yellowish.

AJOWAN.—Ajava; Ajwan; Omam; Bishop's Weed.

The fruit of *Ptychotis Coptica* DC. (*Carum Ajowan* B. et H.) (Fam. *Umbelliferæ*).

The plant is indigenous and cultivated in India, as well as in the countries farther west and in Egypt. The fruit is an important condiment and medicine, being a much-used carminative and intestinal antiseptic in cholera and other diseases presenting similar conditions.

The accompanying illustration answers better than any description. The color is of a very pale-brown and the small tubercles between the ribs are characteristic. It contains 6 oil-tubes. In odor and taste it strongly resembles thyme.

FIG. 7.

Ajowan fruit (× 9).

Ajowan yields 5 or 6 per cent. of volatile oil, having a specific gravity of 0.896. About half of this oil is thymol; the remainder is cymene and a terpene, and is in commerce under the name of *thymene*.

Action and Uses.—Ajowan is practically never used in medicine in this country. It has been considered an antispasmodic and antiseptic. By the physicians of the East it is considered the most powerful of all umbelliferous carminative fruits. When combined with asafetida and rock salt the drug is frequently employed by the natives of India for its carminative effect. It is stated that it may be employed with advantage in chronic bronchitis with excessive secretion. When exhibited in combination with mercury, ajowan has met with favor in the treatment of Asiatic cholera.

The drug is given in the dose of 10 to 30 grains (0.60–2 Gm.) of the Extractum Ptychotis Liquidum P. I., Aqua Ptychotis P. I. Omam water, made by distillation with the fruit, is given in the dose of 1 or 2 fluidounces (30–60 Cc.). The dose of the volatile oil is 1 to 3 minims (0.05–0.20 Cc.).

ALBUMEN.—Albumen.

Albumen Ovi.—White of egg, E.; *Blanc d'œuf*, Fr.; *Eiweiss, Hühnereiweiss*, G.; *Clara de huevo*, Sp.

White of egg is no longer recognized in the pharmacopœias of the world, with the exception of the German, which prescribes a dried form of albumen, to be used in the preparation of iron albuminate and similar compounds.

Egg albumen consists of two or three laminæ, the total average weight for one egg being 23–24 Gm. (355–371 grains). It is composed of 82–88 per cent. of water, and, on an average, 13.32 per cent. of solid matter, as well as minute traces of fat, sugar, and extractive, and yields about 0.65 per cent. of ash. The ash of egg albumen consists of 42 per cent. of potassium chloride, 9 per cent. of sodium chloride, phosphates and sulphates of the alkalies, together with some silica, lime, iron, and magnesia. The organic portion of egg albumen consists of a protein compound, the albumen proper or albumin, having the following average elementary composition: carbon, 53.7 per cent.; nitrogen, 15.5 per cent.; hydrogen, 7.1 per cent.; oxygen, 22.1 per cent.; and sulphur, 1.6 per cent. An aqueous solution of albumen when heated to 75° C. (176° F.) is coagulated. It is precipitated by most mineral and some organic acids, but not by phosphoric or acetic acid. Alcohol coagulates albumen and ether precipitates it, the precipitate being only partially soluble in water. It is soluble in caustic alkalies, but forms precipitates with the salts of most heavy metals; this latter property renders it valuable in

cases of poisoning by salts of mercury, copper, etc. Albumen is also precipitated by volatile oils, camphor, carbolic acid, and tannic acid (see *tannalbin*, under Tannic Acid).

Albumen.—*Albumen Ovi Siccum*, P. G.—*Dried egg albumen*, E.; *Trockenes Hühnereiweiss*, G.—This is prepared by carefully separating the yolk from the white of fresh eggs and passing the latter through a fine bolting-cloth sieve, for the purpose of removing any membranes present. The white of egg is next poured on shallow porcelain plates and completely dried in well-ventilated drying closets at a temperature not exceeding 55° C. (131° F.). Evaporation to dryness in a vacuum apparatus may also be resorted to. The yield amounts to about 100 Gm. of dried albumen from 30 eggs. It occurs in yellowish, amorphous, translucent masses, easily reduced to a coarse powder having but a faint odor and an insipid taste. It should yield a nearly clear solution with 20 parts of water, which is coagulated by heating to 75° C. (176° F.), and is precipitated by lead acetate, mercuric chloride, ferric chloride, cupric sulphate, picric acid, carbolic acid, chloral hydrate, nitric acid, metaphosphoric acid, etc.

The valuation of albumen is made by determining the amount of nitrogen present, usually by Kjeldahl's method (see Nitrogen), the weight of nitrogen found, multiplied by 6.25, expressing the total amount of albumen.

Serum albumen or blood albumen is obtained by collecting the blood of slaughtered animals, allowing the same to coagulate in the cold and draining the serum from the coagulum placed on sieves. Upon subsequent evaporation of the serum dry albumen may be obtained.

Tata-albumen represents a modified form of albumen produced by keeping hen's eggs for several days in a 10 per cent. sodium hydroxide solution at a temperature of 45° C. (113° F.) and then placing the eggs in boiling water for 15 minutes. The albumen, instead of becoming hard and opaque, forms a translucent gelatinous mass which, after leaching with cold water, is readily soluble in boiling water. It may be dried and reduced to powder. Such modified egg albumen will be dissolved by acidulated pepsin solution in one-tenth the time necessary for a solution of a like weight of hard-boiled ordinary egg albumen. It has been recommended as a dietetic.

Tropon is the name applied to a whitish, odorless, and tasteless powder, said to contain 90 per cent. of albumen and about 1 per cent. of inorganic matter. It is free from gelatin and nucleins. The mode of preparing tropon has not been published, but it is said to be obtained from both animal and vegetable matter, and subsequently purified by treatment with hydrogen peroxide. It is intended as a nutrient agent.

Action and Uses.—Albumen is employed as an antidote in poisoning by corrosive sublimate and copper sulphate. Albumen water, made by agitating the white of one egg with one pint of cold water, is a very valuable article of diet in the summer diarrhœa of children. It is also said to be a valuable food in Bright's disease, as it supplies much nutriment and does not increase the albuminuria. A poultice made by coagulating this substance with alum (see Alum) is a valuable application for recent ecchymoses, acute conjunctivitis, and the bites and stings of insects. The ingestion of eggs is said to act as an irritant poison to some individuals, but this is extremely rare. Albumen is also largely employed for the clarification of liquids, because of the property which it has of involving in its coagulum the undissolved particles, after which it either rises to the surface or sinks to the bottom of the container.

ALCOHOL.—Alcohol.

Alcohol ethylicum, Alcohol vini.—*Ethyl alcohol, Ethyl hydroxide*, E.; *Alcool*, Fr.; *Æthylalkohol, Alkohol*, G.

Formula, C_2H_5OH. Molecular weight, 45.7.

Origin.—Alcohol may be obtained synthetically by first preparing acetylene, C_2H_2, by direct union of its elements, converting this into ethylene, C_2H_4, and by combination with the elements of water forming alcohol. It has been detected by Gutzeit (1875) in the juice of a number of plants. Béchamp (1880) proved its presence in the urine

and in the muscles of animals, and in putrid meat; and Muentz (1882) showed it to be contained in minute quantities in air, river-water, and river-soil. It is extensively prepared by the fermentation of saccharine liquids.

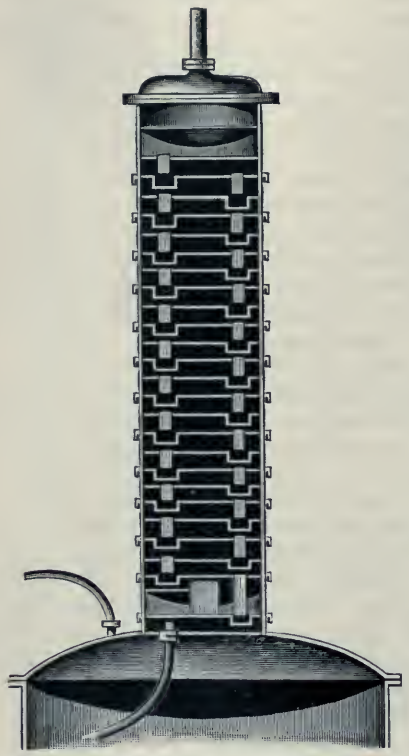
Although the knowledge of various fermented alcoholic liquids dates back to remote antiquity, alcohol does not appear to have been separated from spirituous beverages until about the eighth century, and soon afterward its strength was increased by repeated distillation. Under the name of *fermentation* various processes of decomposition are embraced, apparently depending upon the mere presence of a certain substance or compound, called the *ferment*, which does not enter into chemical composition with the fermenting substance or its products, and is capable of producing a large, if not unlimited, quantity of the latter. The several varieties of fermentation are distinguished from each other by the products obtained; thus, *saccharine* fermentation when starch is converted into dextrin and sugar by diastase; *lactic* fermentation when milk-sugar is transformed into lactic acid by casein; *butyric* fermentation when milk-sugar and lactic acid yield butyric acid in the presence of the same compound; *mucic* fermentation when cane-sugar is changed into mucus and mannite by protein compounds; *alcoholic* or *vinous* fermentation when grape-sugar or fruit-sugar is split into alcohol and carbon dioxide under the influence of yeast; and *acetic* fermentation when alcohol is oxidized to acetic acid. The exact manner in which these ferments act has not yet been determined, and with respect even to vinous fermentation is still a subject of controversy, notwithstanding the numerous experiments performed with the view of solving the problem. When, in 1810, Gay-Lussac demonstrated that sugar solutions would ferment only in the presence of atmospheric air, the process was regarded as depending upon the action of oxygen. Although the presence of organisms in yeast was afterward demonstrated, their connection with the process itself was not ascertained. Liebig (1839) perfected and enlarged the theory which was advanced by Stahl during the preceding century, and regarded fermentation as a metamorphosis induced by nitrogenized substances in a state of decomposition or putrefaction. Chiefly through Pasteur's investigations, begun in 1858, it is now generally conceded that under ordinary circumstances the ferment of alcohol fermentation is of vegetable origin, and consists of the so-called yeast-cells or yeast-plant, *Saccharomyces* (torula, Turpin) *cerevisiæ*, Meyen, the sporules of which are widely diffused in the air, and are thus easily supplied to all liquids, and if their further supply is arrested by admitting only air which has been filtered or passed through sulphuric acid, vinous fermentation does not take place. Alcohol and the other compounds formed during fermentation are regarded not merely as decomposition-products of sugar, but they result from the growth and multiplication of the yeast-plant, the existence of which depends upon the presence of sugar and protein, and by these cells the new compounds are generated.

Preparation.—The first step necessary in the manufacture of alcohol is the saccharine fermentation, known also as the mashing process, for the purpose of converting all the starch of grain or other material into sugar. While in this country grain is almost exclusively used for the manufacture of alcohol, potatoes form the chief source of starch in Europe. During the mashing process large quantities of starchy material are kept in contact with malt and water at a moderately elevated temperature, whereby the starch by the action of diastase (the ferment present in malt, and produced during the partial germination of barley) is first changed to maltodextrin and maltose, and finally all converted into dextrose, apparently by the simple appropriation of water, as shown by the following equations: $3C_6H_{10}O_5$ (starch) $+ H_2O = C_6H_{10}O_5$ (dextrin) $+ C_{12}H_{22}O_{11}$ (maltose); and $C_6H_{10}O_5$ (dextrin) $+ C_{12}H_{22}O_{11}$ (maltose) $+ 2H_2O = 3C_6H_{12}O_6$ (dextrose). The saccharine solution thus obtained is known as *wort*, and, after addition of some yeast is allowed to undergo fermentation at a temperature which is maintained between 15° and 30° C. (59° and 86° F.), whereby a weak alcoholic liquid is produced, due to the splitting up of dextrose into alcohol and carbon dioxide; thus, $C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$. Besides alcohol and carbon dioxide, however, some amyl alcohol and other homologous products, collectively designated as *fusel oil*, are also produced, and Pasteur has shown that small quantities of glycerin (3 per cent.) and succinic acid (0.6 per cent.) are invariably formed. The composition of these so-called low wines or weak spirits varies with the starchy material used in their manufacture; thus, potato starch always yields a much larger proportion of amyl alcohol than grain starch, while grain spirit is contaminated with œnanthic and other ethers. The percentage of alcohol in

mashed and fermenting mixtures never exceeds 14 per cent., since the yeast-plant cannot live in fluid containing a larger percentage.

Distillation of the fermented liquid furnishes a product much richer in alcohol (raw whiskey), which is then further rectified by treatment with recently burned charcoal and subsequent distillation in stills provided with a series of condensers, in the first of which much of the water and amyl alcohol is retained, allowing a purer and stronger alcohol to pass on to the other condensers. For the further removal of water and foreign odors from alcohol, distillation over sodium manganate, anhydrous sodium acetate, and freshly burned lime is employed. For the purpose of facilitating the rectification of alcohol on a large scale, use is made of a distilling column or dephlegmator, which is interposed between the still proper and the condenser, and, as shown in Fig. 8, consists of a series of communicating chambers, one above the other. The vapor rising from the still enters the lowest chamber through a narrow tube projecting upward into the chamber, and, having filled the space, passes into the next compartment through a second tube situated on the opposite side to that through which the vapor entered. By this arrangement the less volatile vapors will be condensed, and the resulting fluid collects on the bottom of each compartment, and if in sufficient quantity to rise above the projecting tube it flows into the next lower chamber, thus gradually separating the less volatile vapors from the more volatile, which latter are finally allowed to pass from the uppermost compartment into the condenser. Naturally the continual influx of hot vapor from the still keeps the liquid collecting on the bottom of the several compartments warmed, whereby the more volatile portions are constantly being vaporized and loss thus avoided.

Fig. 8.



Distilling column or dephlegmator.

During the past eight or nine years alcohol has been successfully produced from cellulose by treating dried peat with very dilute sulphuric acid for several hours at a temperature of 120° C. (248° F.), whereby peat-sugar is formed, which is subsequently fermented with yeast and distilled, yielding as much as 62 liters of absolute alcohol for 1000 kilogrammes of dry peat used (about 15 gallons for each ton).

The pharmacopœias recognize alcohol of different strengths, which latter can be determined by means of a special modification of the hydrometer, known as an alcoholometer. The Tralles' alcoholometer is preferred, because it is graduated to indicate percentage by volume, sinking to 0 on the scale when immersed in distilled water, and each division of the scale indicating 1 per cent. of absolute alcohol. As the density of alcohol varies directly with the temperature, an additive correction must be made in the reading of the percentage scale of the instrument when used at temperatures below the standard, 15.5° C. (60° F.), or a subtractive correction if used above the standard temperature. Every degree of variation on the centigrade scale corresponds to 0.27 per cent., or on the Fahrenheit scale to 0.15 per cent.

Alcohol Absolutum, U. S., Br.; *Alcohol absolutus,* P. G.—*Absolute alcohol,* E.; *Alcool absolu,* Fr.; *Absoluter Alkohol,* G.; *Alcool assoluto,* It.—The article recognized by this name contains not less than 99 per cent. by weight (U. S., Br.), 99.4–99.7 per cent. by volume (P. G.), of ethyl hydroxide, C_2H_5OH The absence of traces of moisture is practically impossible, although the amount is reduced to less than 0.3 per cent. by some manufacturers. In the manufacture of absolute alcohol, high-grade commercial alcohol (95 per cent.), free from foreign odor, is either shaken with freshly burned lime in coarse powder for some time and then heated with the same prior to dis-

tillation, or it is caused to percolate repeatedly through alternate layers of fine and coarse granules of the lime, in an apparatus so arranged as to avoid all contact with air, after which it is transferred, without exposure, to a column-still and distilled at a low temperature, under reduced pressure.

Absolute alcohol is a colorless limpid liquid, of refreshing characteristic odor and pungent taste. It is very hygroscopic, and should be preserved in tightly stoppered bottles, preferably with addition of some anhydrous cupric sulphate or freshly burned lime. It has a specific gravity not higher than 0.797 at 15° C. (59° F.) or 0.790 at 25° C. (77° F.) U. S., 0.7969–0.794 at 15.5° C. (60° F.) Br., 0.796–0.800 at 15° C. (59° F.) P. G., and boils at 78.5° C. (173.3° F.) P. G. Absolute alcohol has a neutral reaction toward litmus, and is miscible in all proportions with ether or water. Whenever alcohol and water are mixed, heat is generated and contraction of volume results, both varying with the proportions of the liquids used. According to Flückiger, the rise of temperature is greatest when 30 parts by weight of absolute alcohol are mixed with 70 parts by weight of water, amounting to 9 degrees C., or 16.2 degrees F., and the greatest contraction occurs when 58 volumes of absolute alcohol are mixed with 54 volumes of water, amounting to a loss of 4 volumes or 3.57 per cent. of the total mixture. It is entirely volatilized, readily inflammable, and burns with a non-luminous blue flame.

A mixture of equal volumes of absolute alcohol and water and one-fifth volume of glycerin, when allowed to evaporate spontaneously from clean odorless filter-paper, should leave no foreign odor. The absence of amyl alcohol or non-volatile carbonizable impurities may be determined by the absence of a red or brown color if after spontaneous evaporation of 25 Cc. of absolute alcohol in a porcelain capsule protected from dust, until only moisture is left, a few drops of colorless concentrated sulphuric acid be added. The red color imparted to absolute alcohol by addition of one-tenth its volume of 0.1 per cent. potassium permanganate solution should not change to yellow in less than 20 minutes (P. G.), indicating the absence of reducing substances, such as aldehyde, etc.

Alcohol, U. S.; *Spiritus Rectificatus,* Br.; *Spiritus,* P. G.—*Spiritus vini rectificatissimus—Alcohol, Rectified spirit, Spirit of wine,* E.; *Alcool,* F.; *Weingeist, Alkohol,* G.; *Alcoole,* It.; *Alcohol, Espiritu rectificado de Vino,* Sp.—This variety of alcohol is by far the most extensively used. It should contain 94.9 per cent. (U. S.), 90 per cent. (Br.), 90–91.2 per cent. (P. G.) by volume of ethyl hydroxide, and has the specific gravity 0.816 at 15.6° C. (60° F.) or 0.809 at 25° C. (77° F.), U. S., 0.834 at 15.5° C. (60° F.), Br., and 0.830–0.834 at 15° C. (59° F.), P. G. It boils at 78° C. (172.4° F.), U. S. Its other properties are nearly identical with those given under Absolute Alcohol.

The present official alcohol corresponds closely to the *deodorized alcohol* of the 1890 Pharmacopœia, both in strength and purity requirements. It should not affect the color of blue or red litmus-paper previously moistened with water, and if 50 Cc. be evaporated in a clean glass vessel, no color or weighable residue should remain. In addition to the following tests for absence of impurities, the Pharmacopœia gives a special test for the presence of methyl alcohol, which latter has at times been found in pharmaceutical preparations, having been fraudulently added to the alcohol used as menstruum. "If 25 Cc. of alcohol be mixed with an equal volume of water and 5 Cc. of glycerin, and the mixture allowed to evaporate spontaneously from a piece of clean, odorless blotting-paper, *no foreign odor* should become perceptible when the last traces of the alcohol leave the paper (absence of fusel oil constituents). If 25 Cc. be allowed to evaporate spontaneously in a porcelain evaporating dish, carefully protected from dust, until the surface of the dish is barely moist, no red or brown color should be produced upon the addition of a few drops of colorless, concentrated sulphuric acid (absence of amyl alcohol, or non-volatile, carbonizable, organic impurities, etc.). If 10 Cc. of alcohol be mixed in a test-tube with 5 Cc. of potassium hydroxide test-solution, the liquid should not at once become dark colored (absence of aldehyde or oak tannin). If 20 Cc. of alcohol be shaken in a clean, glass-stoppered vial with 1 Cc. of silver nitrate test-solution, the mixture should not become more than faintly opalescent, or acquire more than a faint brownish tint when exposed for six hours to diffused daylight (limit of organic impurities, amyl alcohol, aldehyde, etc.)."—U. S.

Methyl Alcohol Test.—Into a test-tube of the capacity of about 40 Cc. 1 Cc. of the alcohol or spirit to be tested should be poured, and, if it be undiluted enough,

distilled water added to make 10 Cc. in all. If the alcohol be already diluted, a correspondingly larger measure of it is taken and diluted to 10 Cc., so that the proportion of the alcohol in the liquid shall not be more than about 10 per cent. by volume. A copper wire spiral (made by winding a piece of No. 18 clean copper wire 1 meter long closely around a glass rod 7 millimeters thick, making a coil about 3 centimeters long, the end of the wire being formed into the handle) is to be heated to redness in a flame free from soot, then plunged steadily quite to the bottom of the liquid in the test-tube and held there for a second or two, then withdrawn and dipped into water to cool. This treatment with red-hot copper should be repeated five or six times, immersing the test-tube in cold water to keep down the temperature of the liquid. The contents of the test-tube are now filtered into a wide test-tube and boiled very gently. If the odor of acetaldehyde be perceptible, the boiling is to be continued until the odor ceases to be distinguished clearly. The liquid is now cooled, and to it is added 1 drop of a solution containing 1 part of resorcinol in 200 parts of water. A portion of this liquid is then poured cautiously into a second tube containing pure sulphuric acid, the tube being held in an inclined position, in such a way that the two liquids shall not mix; this tube is allowed to stand for three minutes, and then slowly rotated. No rose-red ring should show at the line of contact of the two layers (absence of more than 2 per cent. of methyl alcohol. —U. S.

Commercial alcohol does not always come up to the official requirements, averaging as a rule from 91 to 93 per cent. in volume strength; but the variety known as *cologne spirit* generally contains 94–95 per cent. of ethyl alcohol. Alcohol which has been stored in barrels for some time, particularly if the latter were imperfectly charred, is apt to be contaminated with coloring-matter and tannin. As found on the market, ordinary alcohol, and even *cologne spirit*, frequently has an acid reaction, due to acetic acid derived from the aldehyde always more or less present. It is therefore necessary to redistil such alcohol from potassium or calcium hydroxide before using it for analytical work, especially the titration of alkaloids.

Alcohol Dilutum, U. S.; *Spiritus dilutus,* P. G.—*Diluted alcohol,* E.; *Alcool dilué,* Fr.; *Verdünnter Weingeist,* G.—Diluted alcohol of the U. S. P. is made by mixing 500 Cc. each of official alcohol and distilled water. The contraction incident to the mixing of the two liquids amounts to about 3 per cent. at 25° C. (77° F.), and hence if 94.9 per cent. alcohol has been used the mixture, when cool, will contain about 48.9 per cent. by volume of ethyl hydroxide and have a specific gravity of about 0.936 at 15.6° C. (60° F.), or about 0.930 at 25° C. (77° F.). It boils at 82° C. (179.6° F.), and its freedom from impurities is ascertained in the same manner as in the case of a stronger alcohol. If it is desired to make diluted alcohol of any other percentage strength, it may be done as follows: Mix as many volumes, fluidounces or cubic centimeters, of the stronger alcohol as are expressed by the volume percentage of the weaker alcohol, with as many volumes of water, as are expressed by the difference in volume percentage between the stronger and weaker alcohols. When complete contraction has taken place and the mixture has cooled, add sufficient water to bring the volume up to that expressed by the percentage of the stronger alcohol. Thus, to reduce 94 per cent. alcohol to 60 per cent. alcohol, mix 60 fluidounces or cubic centimeters of the stronger alcohol with 34 fluidounces or cubic centimeters of water and subsequently make up the volume to 94 fluidounces or cubic centimeters by addition of more water.

The term *proof spirit* is applied in the United States Custom-House and Internal Revenue Service to a spirit containing 50 per cent. by volume of absolute alcohol.

The Br. Pharmacopœia directs the preparation of 4 varieties of diluted alcohol, designated as 70 per cent., 60 per cent., 45 per cent., and 20 per cent. alcohol, respectively, and having the following specific gravities at 15.5° C. (60° F.): 0.8900, 0.9035, 0.9436, and 0.9760. They are made by mixing 100 volumes of 90 per cent. alcohol with 31.05 volumes of distilled water to produce 70 per cent. alcohol; with 53.65 volumes to produce 60 per cent. alcohol; with 105.34 volumes to produce 45 per cent. alcohol; and with 355.8 volumes to produce 20 per cent. alcohol.

The *spiritus dilutus* of the German Pharmacopœia is made by mixing 7 parts by weight of alcohol with 3 parts of water, and has a specific gravity of 0.892–0.896 at 15° C. (59° F.). It contains 68-69 per cent. by volume of absolute alcohol.

The following table, condensed from one published by Dr. Squibb in *Ephemeris*, vol. ii., will prove convenient for reference:

Specific gravity. (Pure water at 15⅝° C. = 60° F. taken as unity.)		Percentage.		Specific gravity. (Pure water at 15⅝° C. = 60° F. taken as unity.)		Percentage.		Specific gravity. (Pure water at 15⅝° C. = 60° F. taken as unity.)		Percentage.	
At 15⅝° C. = 60° F.	At 25° C. = 77° F.	By weight.	By volume.	At 15⅝° C. = 60° F.	At 25° C. = 77° F.	By weight.	By volume.	At 15⅝° C. = 60° F.	At 25° C. = 77° F.	By weight.	By volume.

Action and Uses.—When alcohol is applied to the skin, it causes a sensation of coolness; if confined, however, it induces redness and irritation. Upon mucous membranes it produces a burning sensation, with blanching and corrugation of the tissue. Internally in moderate amount it acts as a powerful stimulant to all the vital functions, but when given in overdose causes a corresponding depression. The entire nervous system is stimulated by small doses of alcohol. Thoughts follow one another with

greater rapidity than usual. Increased reflex action is noted; the conductivity of nerves, the acuity of sensation, and the activity of muscles, are increased. When the amount ingested is in excess, this effect is very transient, and rambling and incoherence, decreased reflex activity, and incoördination, followed by complete muscular relaxation, loss of sensation, and profound sleep, passing into coma rapidly succeed. When locally applied to peripheral nerves, alcohol at first excites, and later paralyzes them. The force and frequency of the pulse are increased by its stimulating effect upon the heart muscle and its accelerator nerves. Blood-pressure is also increased by the stimulating effect of the drug upon the heart and vasomotor system. Large amounts, however, depress both the heart and peripheral circulation, and toxic doses paralyze them. The respiratory function is increased by moderate doses and depressed by excessive amounts of alcohol, The temperature falls after the administration of this drug. This is due to the dissipation of heat caused by the excessive distribution of hot blood to the periphery. The feeling of warmth felt after the ingestion of alcohol is the result of the distribution of the blood, for while more heat units are manufactured, more also are eliminated. Moderate amounts of alcohol are burned up in the system, and give it force, but any excess is eliminated by the skin, breath, kidneys, and intestines. It inhibits nitrogenous metamorphosis and acts as a conservator of power. Small quantities aid digestion by increasing the blood-supply to the stomach and by stimulating the peptic glands; larger amounts cause indigestion by inhibiting the flow of gastric juices, and by precipitating any peptonizing agent that may be in the stomach. We are very well aware that an immense amount of scientific laboratory research seems to prove that alcohol is never a stimulant and always a depressant. Clinical experience and that of the world in general are so opposed to a belief that the drug is a depressant in its general effects that the older views as to its effects are allowed to stand for our present views.

Alcohol is an invaluable remedy in the treatment of all acute diseases associated with debility. It is probably the best drug to employ in the treatment of enteric fever and other typhoid conditions, as it stimulates the circulation, lessens the nervous symptoms, aids digestion, and, being oxidized in the body, indirectly acts as a food. In the various forms of septic infection, such as erysipelas, septicæmia, and pyæmia, it is employed almost as a routine treatment. It is frequently employed with benefit in wasting diseases due to prolonged suppuration, such as tuberculosis, and may be given to the aged to aid in digestion, inhibit tissue waste, and stimulate their fagging vital functions. In the form of brandy with cracked ice it is an excellent remedy in treating obstinate vomiting. Alcohol is also employed as a rapidly acting circulatory and respiratory stimulant in collapse, during the crisis of the acute infectious diseases, such as pneumonia and scarlet fever, and for the bites of venomous serpents or insects. Under these circumstances it should be given hot and concentrated. When used as a stimulant during prolonged illness, it should be given well diluted. It may be employed as a cooling and antiseptic dressing over inflamed areas and contused wounds. It is valuable as a detergent and stimulating lotion, and is frequently employed as such for the prevention of bedsores. Pure alcohol is also the best antidote for local burns caused by the application of carbolic acid.

In advanced acute alcoholic poisoning, with coma, complete relaxation, and subnormal temperature, the application of external heat, and the administration of circulatory and respiratory stimulants, such as strychine, atropine, and digitalis, are required. Should convulsions occur, counterirritation at the nape of the neck should be employed. Later the bowels should be thoroughly moved with calomel and compound jalap powder or by elaterin. Spirit of Mindererus or aromatic spirit of ammonia may be given to stimulate the stomach, providing it is not too irritable. If gastric inflammation be marked, emollients may be employed. When vomiting occurs, minute pieces of cracked ice may be swallowed or small doses of cocaine or aconite may be given.

The symptoms of chronic poisoning are variable; the most common being cirrhotic changes in the liver and kidneys, mental aberration, multiple neuritis, gastric disorder, and nutritional disturbances. In treating this condition, the patient should be isolated. The drug may then be completely withdrawn, or, better, it may be gradually diminished in amount for a number of days. The depression following should be treated by the use of cloves and capsicum in conjunction with purges and bitters. Small doses of Fowler's

solution may be used if morning vomiting occurs. Highly seasoned nutritious broths and predigested foods should be given in small quantity at frequent intervals.

Brandy and whiskey are more commonly employed than the other preparations containing alcohol. The dose to a child 1 month old is 5 to 10 minims (0.3–0.6 Cc.); 2 months old, 10 to 20 minims (0.60–1.30 Cc.); 3 months old, 20 to 30 minims (1.30–2 Cc.); over 4 months old, 30 to 40 minims (2–2.60 Cc.) every 4 hours. To an adult the dose is from 4 fluidrachms to 2 fluidounces (16–60 Cc.) every 3 or 4 hours. In all cases it should be diluted with hot or cold water: with the former, when required as a rapidly acting stimulant; with the latter, or with food, when it is desired as an aid to digestion.

ALCOHOL AMYLICUM.—Amyl Alcohol.

Amylic alcohol, Primary amyl alcohol, Pentyl alcohol, Amyl hydroxide, E.; *Alcool amylique, Huile de grain*, Fr.; *Amyl-alkohol, Fuselöl*, G.; *Alcool isoamilico*, F. It.

Formula, $C_5H_{11}OH$. Molecular weight, 87.43.

A peculiar alcohol obtained as a by-product through the fermentation of potatoes, also grain, by continuing the distillation at a higher temperature, after the ordinary spirit has ceased to come over. It has been shown to be the product of the action of a bacillus, *B. amylozymicus*, upon starch.

In the Appendix of the B. P., amyl alcohol is recognized in the list of chemical reagents. It is defined as a liquid consisting principally of iso-primary amyl alcohol, $(CH_3)_2:CH.CH_2.CH_2OH$), and distilling between 125° and 142.8° C. (257°–289° F.).

Preparation.—During the alcoholic fermentation of grain, and particularly potatoes, some amyl alcohol is produced, the great bulk of which passes over with the last portions of the first distillation, which are milky, and contain besides amyl some ethyl alcohol and water, and variable quantities of propyl alcohol, isobutyl alcohol, pyridin, furfurol, and other compounds, differing with the source of the fusel oil. The portion remaining in solution with the distilled spirit is obtained in purifying the latter, either by the process of distillation or leaching. Commercial amyl alcohol contains variable quantities (between 20 and 30 per cent.) of ordinary (ethyl) alcohol, of which it cannot readily be completely deprived by fractional distillation and washing with water. Purified amyl alcohol is prepared by washing crude *fusel oil* with concentrated aqueous solutions of common salt (process of B. Hirsh, 1861), or with aqueous solutions of calcium chloride, and submitting the washed residuum to distillation, and collecting the portions distilling between 128° and 131° C. (262.4°–267.8° F.). In a very pure form, it may be obtained by boiling amyl-potassium sulphate with 10 per cent. of sulphuric acid for 5 hours under a reflux condenser, then neutralizing with sodium carbonate, distilling with steam, and further purifying the distillate as above.

Properties.—It is a colorless, thin, oily liquid, having a penetrating and oppressive odor, and a burning acrid taste. Its specific gravity is 0.818 at 15.5° C. (60° F.). It boils at 132° C. (269.6° F.), and evaporates without residue. It is sparingly soluble in water (1 to 40), but miscible in all proportions with alcohol, ether, glacial acetic acid, benzene, petroleum benzin, the lighter hydrocarbons, and fixed and volatile oils, and freely dissolves iodine, camphor, fats, and resins. It is a good solvent for morphine. It acquires a deep-red color with sulphuric acid, and reacts violently with concentrated nitric acid. Exposed to air in contact with platinum-black, it is slowly oxidized, yielding valerianic acid. Heated with an acetate and strong sulphuric acid *amyl acetate* results, having a characteristic pear oil odor. It takes fire with difficulty unless heated to about 55° C. (131° F.), when it burns with a bright flame. As met with in commerce, it contains variable quantities, sometimes 12 per cent., of *active amyl alcohol*, which has the same elementary composition, but turns polarized light to the left and boils at 127° C. (260.6° F.); its barium amyl sulphate is much more soluble in water than the corresponding salt obtained from inactive amyl alcohol. In addition to this, 5 other amyl alcohols have been prepared artificially, varying in their boiling-points between 97° and 137° C. (206.6°–278.6° F.).

Amyl alcohol is *amyl hydroxide*, $C_5H_{11}OH$, and yields a series of compounds homologous with those of ethyl alcohol—namely, amyl ether, $(C_5H_{11})_2O$, amyl aldehyde, or valer-aldehyde, $C_5H_{10}O$, and valerianic acid, $C_5H_{10}O_2$.

Tests.—It should be neutral to litmus, have a specific gravity of 0.814 to 0.818,

boil at 129° to 131° C. (264.2°–267.8° F.), evaporate without residue, not diminish materially in volume when agitated with an equal volume of concentrated aqueous solution of calcium or sodium chloride. When 5 Cc. are mixed with 5 Cc. of concentrated sulphuric acid, not more than a faint-red color should appear, nor should a solution of potassium hydroxide cause discoloration (*furfurol*) when shaken with an equal volume of the alcohol.

Pharmaceutical Uses.—Amyl alcohol is the source of valerianic acid and of various compound ethers (fruit-essences), and may be used as a solvent in the manufacture of alkaloids and other proximate principles.

Action and Uses.—In moderate amounts amyl alcohol acts as a direct stimulant to the nervous system. When given in overdose, it causes giddiness, diplopia, headache, coma, and a subnormal temperature. Later, muscular rigidity or tetanic convulsions, followed by complete muscular relaxation, cyanosis, and a peculiar fruit-like odor of the breath, are sometimes noted. A poisonous amount also acts as a powerful respiratory depressant. Amyl alcohol is practically never employed in medicine at the present time. Formerly it was recommended for the alleviation of the symptoms commonly present in advanced phthisis, but other more potent remedies have supplanted it. It has been employed also in controlling the nervous symptoms occurring in delirium tremens and in overcoming the nervous irritability sometimes found in confirmed alcoholics. Small amounts are nearly always present in ethyl alcohol and in all compounds containing the latter; this is especially true in regard to freshly distilled or raw preparations.

ALCOHOL METHYLICUM.—Methyl Alcohol.

Spiritus pyroxylicus rectificatus.—Pyroligneous (Pyroxylic) spirit or alcohol, Wood alcohol, Wood naphtha, E.; *Alcool méthylique, Alcool formique, Alcool de bois, Esprit de bois, Esprit pyroligneux*, Fr.; *Holzgeist, Methylalkohol*, G.

Formula, CH_3OH. Molecular weight, 31.79.

Preparation.—Methyl alcohol was first noticed by Boyle (1661); its difference from ordinary alcohol was observed by P. Taylor (1812), but it was not correctly characterized until investigated by Dumas and Peligot (1834). Commercially, methyl alcohol is produced principally from the strongly acid solution resulting from the destructive distillation of wood. The distillate on standing separates into a heavy oily layer, tarry and empyreumatic matter, and an aqueous layer containing about 1 per cent. of methyl alcohol, together with acetic acid, acetone, aldehyde, allyl alcohol, empyreumatic oils, and other compounds. The aqueous portion is neutralized with quicklime, subjected to fractional distillation, yielding crude methyl alcohol (*pyroligneous spirit*), from which pure methyl alcohol is obtainable by saturating with fused calcium chloride, resulting in the production of the crystalline compound $CaCl_2.4CH_3OH$, which is stable at the temperature of the water-bath. The crystals are separated, dissolved in water, subjected to fractional distillation and the distillate rectified over lime.

Absolutely pure methyl alcohol is best prepared by distilling crystallized methyl oxalate with solution of potassium hydroxide and then dehydrating the distillate with lime.

Properties.—Pure methyl alcohol is a colorless limpid liquid, of a peculiar somewhat alcoholic odor, and a warm taste. Its specific gravity at 15.5° C. (60° F.) is 0.7997; it boils at 66° C. (150.8° F.); burns with a pale-blue, scarcely luminous flame; is miscible in all proportions with water, alcohol, and ether; dissolves volatile oils and many resins, and in many ways resembles ethyl alcohol in its general properties, the derivatives corresponding with those mentioned under *ethyl alcohol*, being methyl ether $(CH_3)_2O$, methaldehyde or formaldehyde (HCOH), and formic acid (HCO_2H). It is easily oxidized by potassium permanganate in the cold. Crude methyl alcohol used for denaturing spirit should have a specific gravity not to exceed 0.840 at 15° C. (59° F.), and contain about 90 per cent. of methyl alcohol.

Tests.—When 1 Cc. of an aqueous solution of $KMnO_4$ (1:500) is added to 20 Cc. of methyl alcohol, the pink color is destroyed at once, whereas in pure ethyl alcohol the color is permanent for some minutes. If a few Cc. of the alcoholic liquid be boiled in a test-tube and a copper spiral heated to redness be plunged into the vapors, the odor of formic aldehyde becomes recognizable by its pungency (F. A. Sieker). Mulliken and

Scudder's test is the most practical in general use. A spiral of copper wire 2 Cm. in length is superficially oxidized in a Bunsen flame and plunged into 3–4 Cc. of the solution contained in a test-tube, whereby the methyl alcohol is oxidized to formic aldehyde. The operation is repeated several times, the spiral being rinsed each time before reheating. (A concentrated spirit should be diluted with 3 to 4 volumes of water before the oxidation.) Next add 1 drop of a 0.5 per cent. aqueous solution of resorcin, and then carefully pour the mixture upon a few Cc. of concentrated sulphuric acid contained in a test-tube. The presence of methyl alcohol is indicated by the appearance of a *pure rose-red* zone at the line of demarcation, and above it a white to pinkish coagulum increasing ultimately in intensity and rising as purplish flakes. Alcohol, acetone, furfurol, and the ordinary alcohols do not give the reaction. Trillat's test, depending upon the formation of a pure blue color from the interaction of the oxidized methyl alcohol and dimethylamine (*Compt. rend.*, cxxvii. 234; *Proc. Am. Pharm. Assoc.*, vol. xlvii. p. 690), serves to identify methyl in ethyl alcohol.

Methyl alcohol is much used in the arts as a solvent of resinous varnishes, and as a base for the manufacture of formic aldehyde. Its high heating value makes it a cheap fuel substitute for alcohol.

For some years a purified methyl alcohol, containing 97–98.5 per cent. of CH_3OH, has been offered, under the name *Columbian Spirit*, for pharmaceutical purposes. It should never be used, however, for internal remedies, since even the purest methyl alcohol has been shown to be decidedly toxic. Recent investigations also point to the danger of using methyl alcohol in liniments and other external remedies.

Action and Uses.—Because of its comparative cheapness, wood alcohol is largely employed in the arts as a substitute for ethyl alcohol. It should never be employed as a substitute for the latter in medicine, however, because of its decidedly poisonous properties. It is a sedative and narcotic, but is never used in medicine in this country. The drug has been recommended, however, in the treatment of pulmonary tuberculosis, chronic diarrhœa, and dysentery. When excessive quantities of methyl alcohol are ingested, nausea, vomiting, violent headache, vertigo, coma, and amblyopia of varying degrees frequently result. A number of deaths and many cases of permanent blindness have been reported as the result of ingestion of this drug, when employed by unscrupulous manufacturers in the preparation of the various essences, especially of ginger and peppermint, for sale as a beverage in "local-option" towns.

The internal dose of wood alcohol is stated to be from 10 to 20 minims (0.60–1.3 Cc.) several times daily.

ALETRIS.—Unicorn Root.

Ague-root, Blazing-star, Crow-corn, False devil's-bit, Husk-wort or Star-grass, E.; *Mehlige Aletris; Einhornwurzel*, G.; *Aletris farineux*, Fr.

The dried rhizome and roots of *Aletris farinosa* L. (Fam. *Hæmoderaceæ*).

The habit and appearance of both plant and drug are displayed in the accompanying illustration. The plant is from a half to a yard high, and nearly smooth, the specific name referring to the mealy indumentum of the whitish flowers. It grows in low sandy soil in the eastern half of the United States, especially in the southern pine-barrens.

The rhizome consists of 4 to 6 rather indistinct joints, is brown-gray externally, white internally, breaks with a mealy fracture, with protruding scattered wood-bundles, is inodorous, and has an amylaceous, afterward acrid, but not bitter taste. It is grayish-brown, bears papery remains of the leaf-bases and more or less of the light-colored, thin, tough roots.

The only constituents known to exist in aletris are an abundance of starch and a bitter principle, soluble in both water and alcohol, more so in the latter.

False unicorn root, Devil's bit, Blazing star, Drooping starwart, and *Red-seed* are names which have been applied to the rhizome of *Chamælirium luteum* (L.) A. Gray (*Veratrum l.* L.; *C. Carolinianum* Willd.; *Helonias dioica* Pursh.—Fam. *Melanthaceæ*), of eastern North America. By others, the terms "False" and "True" are transposed. By far the better custom is to call them by their technical names. The flowers are in dense terminal racemes, that of the pistillate plant erect, that of the staminate drooping at the summit, like a beautiful creamy white plume. The rhizome is frequently substituted for or mixed with aletris. Our illustration shows the two contrasted. Aletris is tufted and more flattened at the crown,

and its roots are finer and lighter colored. Chamælirium is bitter. The rhizome contains 10 per cent. of *chamælirin*, an amorphous, light-yellowish-red, bitter powder, freely soluble,

FIG. 9.

A–D, *Aletris farinosa*; E, *Chamælirium luteum*.
(A and B, × ½; C, enlarged; D and E, Nat.)

with frothing, like saponin, in water and alcohol, and insoluble in chloroform. Dilute acids change it to glucose and *chamæliretin*, a resinous body soluble in water. The so-called *helonin* of the eclectics is the hydro-alcoholic extract of the rhizome.

Pharmaceutical Preparation.—FLUIDEXTRACT OF ALETRIS, N. F.

Action and Uses.—Aletris is a simple bitter which at present is not used to any great extent. It has been recommended as a powerful uterine tonic, and is said to possess diuretic, emetic, purgative, and antirheumatic properties, and it has been reported as successful in the treatment of spermatorrhœa, but is probably of little use in this condition.

Aletris may be administered in the form of an infusion (50 Gm. in 1000 Cc. of water) in 4 fluidrachm (16 Cc.) doses.

The dose of the powdered drug is 10 grains (0.60 Gm.).

ALISMACEÆ.—The Water-plantain Family.

A family of 10 genera and about 50 species, aquatics, distributed through most tropical and temperate regions. The rhizomes of *Sagittaria sagittifolia* L. (*Wapatoo*) and *S. Chinensis* (*Ts'ze-ku*) are used respectively by the North American Indians and the Chinese as starchy foods, as are some other species. That of *Echinodorus ellipticus* Mich., of Brazil, is used as an astringent. The family in general contains acrid juices, on account of which a number of species are used as diuretics and antiscorbutics. The following has been considerably used medicinally and is a drug of commerce.

Alisma (*Water-plantain*); *Froschlöffel, Wasserwegerich*, G.; *Plantain d'eau, Pain de grenouilles*, Fr.—The plant, and more especially the rhizome, of *Alisma Plantago-aquatica* L.

The plant grows in shallow water or muddy places and is apparently indigenous throughout the entire north temperate zone.

The rhizome consists of 2 or 3 united fleshy tuberous pieces, which vary in shape from oblong to subglobular, externally of a blackish color and beset with numerous fine roots, inter-

nally white and with scattered wood-bundles, and is, in the fresh state, of a disagreeable sharp odor and taste. The leaves are on long petioles, very smooth, ovate, oblong or lanceolate, acute, frequently with a heart-shaped base, 5- to 9-nerved, light green, and of an acrid taste. The scape is about 2 feet (60 Cm.) high, 3-edged, and bears a loose panicle of whitish perfect flowers, having 3 sepals, 3 petals, 6 stamens, and numerous pistils upon a flattish receptacle.

Water-plantain contains a butyraceous pungent volatile oil, of which Zuch (1818) obtained 0.6 per cent. Neljubin found in it also an acrid resin. Alisma is rarely employed in medicine at the present day. The rhizome formerly enjoyed some repute as a specific in hydrophobia, but its employment in this disease has been abandoned. The bruised leaves are rubefacient and have been locally applied over bruises and swellings. The drug has been recommended in renal calculus, dysentery, chorea, and epilepsy, but is of doubtful efficacy in any of these conditions. The dose of the powdered rhizome is 8 grains (0.50 Gm.); of the leaves, 15 grains (1 Gm.). A decoction of the leaves (50 Gm. in 1000 Cc. of boiling water) may be given in doses of 4 to 8 fluidrachms (16–30 Cc.).

ALLIUM.—Garlic.

Poor man's treacle, E.; *Knoblauch. Gartenlauch*, G.; *Bulbus allii.—Ail.* Fr.

The undried bulb of *Allium sativum* L. (Fam. *Liliaceæ*).

This well-known culinary plant is indigenous to central Asia, and is everywhere cultivated, exhibiting several well-marked varieties, some with white, some with red bulbs. All parts of the plant are active.

Bulb an inch or two broad, subglobular, compound, surrounded by a few dry membranaceous scales, which cover the remnant of the upright stem and the 5 to 8 small bulbs arranged in a circle around its base. These bulblets are oblong in outline, compressed from both sides, wedge-shaped toward the stem, and rounded upon the back. They consist of a few thick fleshy scales and a short fleshy axis. Garlic has a peculiar pungent and disagreeable odor and an acrid, burning taste. It is used in the fresh state only.

Garlic is best preserved in a dry place at a moderate temperature, in which state it slowly parts with its water. If put into a jar with the addition of a small quantity of alcohol—about 2 ounces to the quart—the vitality of the bulbs is destroyed, and they retain their properties for a long period, but change in color, acquiring a brownish, somewhat diaphanous appearance.

Constituents.—Besides the cellular tissue, garlic contains between 50 and 60 per cent. of water, 35 per cent. of mucilage, some albumin, sugar, starch, and about 0.25 per cent. of volatile oil, to which its odor and taste are due. In its crude state *oil of garlic* is of a dark brown-yellow color, heavier than water, of a very repulsive taste. It contains a sulphur-bearing compound, formerly believed to be allyl-sulphide, but now known not to be so. Terpene is wanting.

Action and Uses.—Locally applied, garlic acts as an irritant and rubefacient. Internally it is a carminative, causing an increase in the secretion of gastric juice. If given in overdose, it may produce nausea, vomiting, colicky pains, and purging. In small amounts it acts as a condiment and aids in the digestion and absorption of food. In chronic inflammation of the bronchial tubes, garlic in the form of a poultice applied to the chest and given internally in boiled milk will often be found of service. Poultices of this drug when applied to the spine are recommended in infantile convulsions, and may be applied over the abdomen in gastro-intestinal catarrh. In the dose of 2 to 5 minims (0.10–0.30 Cc.) the oil of garlic is said to relieve nervous vomiting. Internally it is commonly employed as the syrup of garlic (Syrupus Allii) in the dose of ½ to 1 fluidrachm (2–4 Cc.) to a child or to an adult.

Other Species.—The genus *Allium* contains about 250 species, distributed over almost the entire world, in temperate and subtropical regions. Many of them are highly ornamental, while others, the leek (*A. Porrum* L.), the onion (*A. Cepa* L.), the chives (*A. Schœnoprasum* L.), the shallot (*A. Ascalonium* L.), are well-known foods. Many indicate by their odor the presence of constituents similar to that of garlic, which have indeed been extracted from some of them. *A. Victorialis* L., *Allermannsharnisch*, *Mäuselauch*, *Radix Victorialis longæ*, of southern Europe, is used as an anthelmintic. The bulb of *A. Macleanii* Back., of Afghanistan, is the source of the "Royal Salep" of history. It has almost no alliaceous odor and apparently contains only gum. That of *A. xiphopetalium* Aitch. et Back., is also believed to have yielded a portion of this product, but has a distinct odor. The volatile oil of the common onion was found by Semmler to consist mainly of $C_6H_{12}S_2$.

ALOE, *U. S., Br., P. G., F. It.*—Aloes.

Acibar, Sp.

Definition.—The inspissated juice of the leaves of *Aloe vera* (Linné) Webb, *Aloe Chinensis* Baker, *Aloe Perryi* Baker, or other species of *Aloe* (Fam. *Liliaceæ*).

Aloe Socotrina, Socotrine or Sucotrin aloes, Socotrinische Aloe or Zanzibar Aloe, is from *A. Perryi* Baker, and perhaps also from *A. Succotrina* Lam. (*A. vera* Mill., *non* L.). Aloe Barbadensis, Curaçao, Barbadoes, or (U. S. terminology) Hepatic aloes, Aloès hépathique, Aloes des Barbades, ou de la Jamaique, is from *A. vera* (L.) Webb (*A. perfoliata vera* L.; *A. vulgaris* Lam.; *A. Barbadensis* Mill.; *A. Indica* Royle: *A. littoralis* Koenig; *A. Chinensis* Baker).

Some doubt still exists as to the identity of the Barbadoes and other West Indian products. The producers declare the plants identical, but Holmes appears to have shown that the Curaçao article is yielded by *A. Chinensis* Baker, and he insists that the appreciable differences in the products may be due to differences in the plants.

Regarding aloin as the active constituent of aloes, various propositions have been made to state its percentage as a part of the definition, either retaining the Socotrine and Curaçao varieties under separate titles or uniting them, or recognizing under one title any variety containing the required percentage of aloin. Certainly, a very large portion of that now sold for Socotrine is in reality Curaçao aloes.

The Fr. and It. Pharmacopœias recognize *Aloe Barbadensis* and *Aloe Capensis* (*Cape aloes, Kapaloe, Aloes du Cap, Aloe lucida* or *Glassy aloes*), from *A. ferox* Mill. and *A. spicata* L. The Belgian, Portuguese, and Spanish recognize all three varieties. The Austrian, Danish, Dutch, Norwegian, Russian, Swedish, and Swiss recognize only *Aloe Capensis*. In spite of the fact last stated, Cape aloes is in growing disfavor.

Origin.—The species yielding Socotrine aloes are natives of eastern Africa, our sole source of supply; that yielding Barbadoes aloes (if distinct from *A. Chinensis*, source of Curaçao aloes) is native of northwestern Africa. Some authorities regard it as native also of India, while others consider it introduced there, as it is in the West Indies, whence come our supplies. The aloe plants resemble small century plants, with bayonet-shaped fleshy and succulent leaves and racemose or spicate yellow or orange-red tubular flowers.

The methods of collection and preparation differ somewhat in different localities, but the general principles are the same. Two juices, one insipid, thick and mucilaginous, in the central portion, the other thin, watery, yellow, and very bitter, in the superficial portions, exist in the leaves. The latter only is useful. Since the leaves are nutritive (it is said that after exhaustion they are used as cattle-food), it appears quite likely that this superficial active juice exerts a protective influence in favor of the plant. The thick juice, expressed doubtless with more or less of the other, is used for poultices, and is credited, in the producing countries, with strong emmenagogue properties. Collection occurs soon after the rainy season, when the juice is neither too scanty nor too watery. The leaves being cut off close to the stem, are quickly laid in a slanting or vertical position, so that the thin juice will drain into suitable receptacles. Great care is taken to avoid pressure, even that resulting from the weight of too large a mass, because of the tendency to expel the undesirable juice. The degree of care exercised in the collection and preservation of the juice varies, being greatest probably in the West Indies. Evaporation may be performed by artificial heat, as in the West Indies, or allowed to occur spontaneously, as in the case of the Socotrine variety. If the degree of artificial heat be moderate, the medicinal activity remains unaltered, though it apparently imparts a heavier odor. Evaporation (in Curaçao) of the juice at once, below the boiling-point, yields a variety called "Capey," because of its greater luster, and yielding a yellowish powder; but if kept a year and then evaporated, the surface is dull, the odor suggesting fermentation, the powder brownish, and the water-soluble matter 4 to 13 per cent. less (Holmes). The product may be stored for shipment in casks, kegs, tin-lined boxes, or skins of animals (as is usual with the Socotrine variety), or in boxes of 60 to 100 pounds or emptied gourds containing 2 to 50 pounds, as in the West Indies. The latter is said to improve, and it brings a higher price, upon keeping. It is produced chiefly in Curaçao, Aruba, and Bonaire. Barbadoes no longer produces any, but a much higher price is frequently obtained for Curaçao aloes sold as Barbadoes. Curaçao aloes was formerly much used for producing a brown dye. The most expensive and highly esteemed product is Socotrine aloes in kegs

or, as here mostly marketed, in cans. That contained in monkey or goat skins brings a lower price, but is probably equal in quality, though apt to contain stones, nails, etc.

Description.—ALOE SOCOTRINA.—Usually solid, with the central portion often semifluid or soft, of a yellow-brown color, bright-yellow, rarely with a slight orange tint, where freshly abraded, the harder portions having a lightly conchoidal fracture with little or no luster. Occasionally liquid, then usually separating into two layers, the upper transparent and liquid, the lower a brown-yellow, semisolid, crystalline mass; more rarely, and an inferior form, homogeneous, of the consistency of soft tar and dark-brown or nearly black. Odor, when breathed upon, finely aromatic, somewhat resembling saffron or myrrh; the powder is of a bright- or slightly brownish-yellow, exhibiting crystals under the microscope, as does its mixture with alcohol, and should not cake when dried and then heated to 100° C. (212° F.). About 50 per cent. soluble in cold water, almost completely soluble in alcohol and boiling water, from the latter solution, on cooling, about 40 to 60 per cent. separating, which constitutes the so-called *resin of aloes*, and which is taken up by alkalies and reprecipitated by acids; 4 to 5.5 per cent. soluble in ether, the latter acquiring only a slight yellowish color. In contact with chloroform the latter remains uncolored, even when heated to boiling. With nitric acid it assumes a reddish-brown color, and mixed with sulphuric acid a blue color should not be imparted by blowing over the mixture the vapor of nitric acid.

ALOE BARBADENSIS (including the Curaçao product).—Rather hard and brittle, opaque or translucent in thin splinters, orange-brown to deep-brown (the genuine Barbadoes usually a little lighter), bright orange-yellow on the freshly abraded surface; fracture slightly conchoidal, of a waxy luster or in the "Capey" form resinous or barely glassy. Odor, when breathed upon, stronger but less fine and agreeable than that of Socotrine aloes. Not more than 30 per cent. should be soluble in cold water nor more than 10 per cent. in ether, the latter acquiring a yellow color. With alcohol, boiling water, and chloroform, it acts similarly to Socotrine aloes, and its powder or alcoholic mixture exhibits similar crystals. With nitric acid it acquires a red color; mixed with sulphuric acid, no change, or only a faint greenish-blue tint, should be acquired upon blowing over it the vapor of nitric acid; upon adding a little copper sulphate solution, then a saturated salt solution, an intense carmine color should be developed (Kremel). The Italian Pharmacopœia requires not more than 8 per cent. of water or 2 per cent. of ash, the Swiss not more than 1.5 per cent. of ash, the Russian not more than 4 per cent.

Composition.—The activity of the drug probably resides in *emodin* or *trioxymethylanthraquinone* ($C_{15}H_{10}O_5$), which crystallizes in orange-red needles, and bitter crystalline *aloin*. Aloes also contains resin, and a minute quantity of a pale-yellow volatile oil, different in the different varieties, and to which the disagreeable odor is due. Cold water extracts the active principles, the insoluble inactive matter being taken up by boiling water and deposited again on cooling. Aloes leaves 1 to 4 per cent. of ash. The yield of *aloin* varies from 4.5 to 9 per cent. (Treumann) in Cape aloes, 6 per cent. in Uganda, 7.5 to 10 per cent. in Socotrine, and 18 to 25 per cent. in Barbadoes or Curaçoa aloes. Treumann estimates that less than half the aloin in the drug can be extracted. It is probable that at least 3 different aloins exist, their respective sources being indicated by a prefix, viz., *socaloin* ($C_{15}H_{16}O_7$) and *barbaloin* ($C_{17}H_{20}O_7$ or $C_{16}H_{16}O_7 3H_{20}$), with similar properties, and *nataloin* ($C_{16}H_{18}O_7$ or $C_{25}H_{28}O_{11}$), which is little purgative to man. *Emodin*, but recently discovered, occurs in Cape and Barbadoes aloes (0.15 to 2 per cent.), but not in the Natal or Socotrine varieties. It develops in aloin exposed to the air, or heated with a 1 per cent. solution of potassium hydroxide, and is possibly the *aloëtin* of Stoeder. Like aloin, the resin differs according to its source, the different kinds being esters of various acids with aloresino-tannol. That of Barbadoes aloes is the cinnamic ester, and that of Cape aloes the paracumaric ester. The yield varies from 12 to 50 per cent.

Pharmaceutical Preparations.—EXTRACT OF ALOES, U. S. P.; PILLS OF ALOES, U. S. P.; PILLS OF ALOES AND ASAFŒTIDA, U. S. P.; PILLS OF ALOES AND IRON, U. S. P.; PILLS OF ALOES AND MASTIC, U. S. P.; PILLS OF ALOES AND MYRRH, U. S. P.; PURIFIED ALOES, U. S. P.; TINCTURE OF ALOES, U. S. P.; TINCTURE OF ALOES AND MYRRH, U. S. P.; PILLS OF ALOES AND PODOPHYLLUM, N. F.

Aloe Purificata, U. S.—*Purified Aloes*, E.; *Aloès depuré*, Fr.; *Gereinigte Aloe*, G.—The official directions for purifying aloes are to melt 1000 Gm. of aloes by means of a water-bath, and, after addition of 200 Cc. of alcohol, to stir the mixture well and pass it through a No. 60 sieve which has just been dipped into boiling water. The strained mixture is evaporated on a water-bath with constant stirring until a thread of the mass, upon cooling, becomes brittle; the product may then be broken into lumps of convenient size and preserved in well-closed containers in a cool, dry place.

The process is strictly one of mechanical purification, the object being the removal

of pieces of wood, leaves, and other foreign matter usually found in aloes; the alcohol is added simply to render the melted aloes more fluid and to facilitate straining. By dipping the sieve into boiling water, chilling and adhesion of the mixture are avoided.

Action and Uses.—Aloes has a disagreeably bitter taste and leaves an unpleasant after-sensation in the mouth. Because of its bitter principle it has been employed as a stomachic and tonic in depraved conditions of the stomach when attended with a sluggish liver or torpor of the large intestine, and increases the peristaltic action, but when given for a long time probably causes some atony of the muscular coat.

Aloes is a slowly acting purge, and its efficacy is increased when it is combined with alkalies such as soap. It rarely produces a watery stool, as it does not deplete, but, on the other hand, congests the bloodvessels of the abdominal viscera. It may be employed in habitual constipation resulting from impaired peristalsis, but its use should be discontinued as early as possible. If given in large doses, tenesmus and irritation of the large bowel may occur, but if combined with other resinous laxatives this may in a great measure be overcome.

It is stated by some that aloes possesses a certain curative power in the treatment of hemorrhoids; and in that variety resulting from a sluggish venous circulation, and not attended by inflammation, the drug may be of benefit. That this is true, however, is disputed by many physicians.

Aloes distinctly increases the menstrual flow. Whether this is due to some direct influence of the drug upon the uterus itself or whether it is caused by an extension of the irritation of the rectum to the uterus, is not definitely known, but it probably acts by increasing pelvic congestion. Amenorrhœa and menorrhagia resulting from anæmia are frequently relieved by aloes when combined with iron and other suitable remedies.

In the form of an enema the drug may be employed with benefit in the treatment of patients suffering from round worms, and as an injection it may be used with good result in chronic gonorrhœa.

Aloes should not be employed as a purge if irritation or inflammation of the intestine is present. It should not be used in the treatment of constipation in plethoric persons or in nursing women, as it may purge the nursling. The drug is contraindicated in pregnancy, proctitis, and in fevered states.

Because of its disagreeable taste aloes is commonly given in pill-form. Its usual dose is from 2 to 5 grains (0.12–0.30 Gm.), but as much as 20 grains (1.30 Gm.) may be given.

Other Varieties.—Aloe Capensis (synonyms and sources stated above).—Usually in strong boxes, frequently lined with sheep skin; color dark-brown or red-black, often with a greenish or olive tint and of a glassy luster; hard and brittle, the fracture strongly conchoidal, translucent in thin splinters; odor disagreeable, sourish; taste very bitter; powder yellowish-brown or greenish-brown, free from crystals; more soluble than either of the above in alcohol and water, and the solutions darker; from 1.5 to 6.5 per cent. soluble in ether. As much as 9 per cent. of aloin has been obtained from it, but the yield is ordinarily 5 to 7 per cent. Its production is probably equal to that of all other varieties combined. It is mostly used in Germany and southern Europe, but little in England and the United States.

Aloe Natalensis, or Natal Aloes.—Light or grayish liver-brown, without luster and opaque, exhibiting crystals under the microscope, almost odorless, and with less taste than any other, practically insoluble in alcohol or water. Its solution in sulphuric acid becomes blue upon exposure to the vapor of nitric acid. It is not known from which of the numerous African species this variety is derived.

Moka Aloes is probably produced from *A Succotrina* Lam., of eastern Africa, and is sold as Socotrine aloes, but is very inferior to the genuine. It is darker, softer, and of an unpleasant odor, and probably includes that of tarry consistence and color already described under Socotrine aloes.

Indian Aloes, or Jafferabad aloes, resembles Socotrine, but is harder, darker, and more glassy, its powder pale-brown, its odor and taste disagreeable. It is probably yielded by *A. Abyssinica* Lam., of northeastern Africa.

Zanzibar, while a general synonym for "Socotrine," is chiefly applied to the hepatic form, and especially to that arriving in monkey skins.

Hepatic has three significations: (1) the liver-colored variety of Zanzibar aloes; (2) (as chiefly applied in the United States) the Curaçao variety; (3) any liver-colored form.

Caballine Aloes was a very inferior variety, of African production, largely used in veterinary practice, but which has now disappeared from commerce.

ALOINUM, *U. S.*, *Br.*—Aloin.

The name aloin is used, both commercially and in the pharmacopœias, to designate the neutral, bitter, crystalline principle of aloes, irrespective of the source. The U. S. P. states that it is chiefly prepared from Curaçao aloes, whereas the Br. P. designates aloin as a product extracted from Barbadoes or Socotrine aloes. It is more than probable that a very large proportion of the aloin sold in this country is derived from Curaçao aloes, as this variety is much richer in aloin than either Barbadoes or Socotrine aloes, and, moreover, comparatively little of the latter variety reaches this market. Cape aloes, which was formerly supposed not to contain any crystalline aloin, has been shown to contain the same, and the name *capaloin* has been given to it. Tschirch, in 1898, succeeded in crystallizing capaloin from alcohol and ether in the form of colorless needles.

Various methods have been proposed for the manufacture of aloin, the best known of which is the treatment of aloes with hot water acidulated with either hydrochloric or sulphuric acid; after the infusion has been allowed to stand for a day it is carefully decanted from sediment, concentrated at a moderate temperature, and set aside in a cold place, when crystals or crystalline crusts of aloin will separate. The aloin may then be purified by recrystallization from hot water or very dilute alcohol. The addition of a little acid has been found advantageous in avoiding the contamination of aloin with non-crystallizable matter, which is less soluble in acidulated water than in plain water. A more recent method, suggested by Schaefer, depends upon the property of aloin of forming very difficultly soluble compounds with the alkaline earths in ammoniacal solution, which, upon decomposition with an acid, yield aloin. The following method for determining the aloin content in aloes indicates the process of manufacture for aloin on a large scale: 50 Gm. of aloes are mixed with 300 Cc. of hot water, with the addition of a few drops of hydrochloric acid. On cooling, the solution is decanted from the separated resin, mixed rapidly with 50 Cc. of 20 per cent. ammonia water and then with a solution of 15 Gm. of calcium chloride in 30 Cc. of water. On stirring rapidly, the aloin-calcium compound separates out and is collected after 15 minutes, the water is removed by draining or in a centrifugal machine, and the lime salt decomposed by triturating it in a mortar with a slight excess of hydrochloric acid. The resulting mixture of aloin and calcium chloride is then dissolved in a small quantity of hot water, filtered, the filter washed with hot water, and the aloin crystallized out at a low temperature with the aid of ice. As much as 30 per cent. of aloin, in fine, light-yellow crystals, has been obtained from commercial aloes by this method. The average yield of aloin from the different commercial varieties of aloes varies from 4 to 20 per cent. and over.

The names barbaloin, socaloin, nataloin, and capaloin are applied to the products obtained from different commercial varieties of aloes. Ugandaloin and Curaçaoaloin are identical with capaloin and barbaloin, respectively. These varieties of aloin differ in composition, solubility, and certain chemical reactions.

Properties.—Aloin occurs as a microcrystalline powder or minute acicular crystals, lemon-yellow to yellowish-brown in color, possessing a slight odor of aloes and an intensely bitter taste. It is slightly hygroscopic, the air-dried powder containing 1 molecule of water of crystallization at 100° C. (212° F.). Aloin is soluble in about 65 parts of water, 10.75 parts of alcohol, 664 parts of ether, 4260 parts of chloroform, 3120 parts of benzene, 1475 parts of petroleum benzin, and 21 parts of acetone, at 25° C. (77° F.). The melting-point of aloin which has been dried over sulphuric acid is about 147° C. (296.6° F.). When ignited, it is consumed without leaving a residue. Aloin dissolves in water, forming a yellow solution, which is neutral to litmus-paper, turns brown on standing, and has an intensely bitter taste. Ammonia-water and caustic alkalies dissolve aloin, forming a yellow solution, soon turning red and exhibiting a greenish-red fluorescence. Aloin when added to alkaline solutions is rapidly decomposed, but if mixed with acid solutions decomposition is slower. Added in minute quantity to concentrated sulphuric acid, aloin forms a yellowish-red solution, which, upon addition of a small crystal of potassium dichromate, changes to an olive green, then to a dark green, and, finally, on standing, to a blue. If a large amount of potassium dichromate be used, the yellowish-red solution first turns purple, then brown, and finally green. Bromine-water added to an aqueous solution of aloin produces a pink color. Gold chloride test-solution when added to an aqueous solution of aloin turns it carmine red, changing later to violet. A drop of ferric chloride test-solution added to an alcoholic solution of aloin

produces a brownish-green color.—U. S. The peculiar color reactions from orange to deep cherry red, observed when 5 per cent. ammonia-water is shaken with an ethereal extract, obtained from a decoction of aloes by agitation with ether, known as Borntraeger's reaction, are due to emodin, and not to aloin; pure aloin, freed from emodin, fails to show these colors.

Tests.—Aloin made from Curaçao aloes forms a cherry-red solution with nitric acid (distinction from nataloin, socaloin, and capaloin). On shaking 1 Gm. of aloin with 10 Cc. of benzene for 1 minute and filtering, the filtrate should not impart more than a faint pink color to an equal volume of 5 per cent. ammonia-water when shaken with it (limit of emodin). If to a dilute solution of aloin obtained from Curaçao aloes, 1 drop of copper sulphate test-solution be added, a bright-yellow color will be produced; upon adding a few drops of a solution of sodium chloride, the liquid will acquire a red color, and upon the further addition of a little alcohol the color will be changed to violet (distinction from nataloin and capaloin).—U. S. This last test, which is known as Klunge's reaction, depends, according to Tschirch, upon the presence of a small proportion (0.4 to 0.5 per cent.) of isobarbaloin, an isomeric body. The red color obtained in the reaction will be intensified if, in place of the sodium chloride, a small quantity of hydrocyanic acid be added. Aloin of commerce is sometimes contaminated with resinous and other matter, which can be detected by imperfect solubility of the sample in cold water.

Barbaloin. *Curaçaoaloin.* $C_{16}H_{16}O_7 + 3H_2O$ (Br.).—This is the chief aloin of the market, although largely made from Curaçao aloes. It conforms to the description and requirements given above. Boiled with nitric acid, barbaloin yields chrysammic acid, but if oxidized by means of potassium dichromate and sulphuric acid, aloxanthin (methyltetroxyanthraquinone), $C_{14}H_3.CH_3(OH)_4O_2$, results.

Socaloin ($C_{34}H_{38}O_{15} + 5H_2O$, Flückiger; $C_{15}H_{16}O_7$, Sommaruga and Egger), also known as *zanaloin*, may be obtained from Zanzibar aloes by treating the same repeatedly with cold 35 per cent. alcohol and expressing after each treatment. The residue is treated with hot alcohol and the resulting solution allowed to crystallize. It occurs in small, yellow, prismatic crystals, which are soluble at 15.5° C. (60° F.) in 90 parts of water, 9 parts of acetic ether, or 380 parts of ether. Treated with nitric acid it yields, like barbaloin, chrysammic acid, and with chromic acid, aloxanthin.

Nataloin ($C_{25}H_{28}O_{11}$, Tilden; $C_{16}H_{18}O_7$, Sommaruga and Egger).—This variety of aloin is obtained from Natal aloes, after treatment with warm 94 per cent. alcohol, by crystallizing the insoluble residue from boiling alcohol. It occurs in the form of yellowish rectangular plates, melting at 210° C. (410° F.), and soluble in 60 parts of 90 per cent. alcohol or 50 parts of acetic ether, but requiring 230 parts of absolute alcohol or 1250 parts of ether for solution. Nataloin may be readily distinguished from barbaloin and socaloin by the following reaction, known as Histed's reaction: If nataloin be dissolved in concentrated sulphuric acid and a glass rod previously dipped into fuming nitric acid be passed over the solution, the latter assumes a green color, changing to blue, then to violet, and finally to orange red. Barbaloin and socaloin are scarcely changed by this treatment. Natal aloin when treated with oxidizing agents yields neither chrysammic acid nor aloxanthin, but, instead, oxalic and picric acids (E. Schmidt).

Action and Uses.—Aloin is used very largely in place of aloes itself in laxative pills (see ALOES). The dose of aloin is ¼ grain (0.015 Gm.), usually given in pill.

ALSTONIA.—Dita Bark.

Ditarinde, G.; *Écorce de dita*, Fr.; *Pali-mari*, Ind.

The dried bark of *Alstonia scholaris* (L.) R. Br. (*Echites, s.* L.—Fam. *Apocynaceæ*).

Dita Bark is the product of a stately, fragrant-flowered tree of the East Indies, eastern Australia, and the Philippines and adjacent islands, which is held is superstitious reverence by the natives. Its wood yields a valuable timber. The bark is said to yield a yellow dye in Australia. It is a widely used antiperiodic and tonic in the countries where it grows.

The bark is in curved pieces, of variable size and 3 to 8 Mm. (⅛ to ⅓ In.) thick. It is externally of a yellowish color, has a scaly appearance from its longitudinal and transverse fissures, and is not infrequently marked with small black spots. Internally, it is light yellowish-brown, the inner surface brown-gray and longitudinally striate. The bark breaks with a short, or rather horny, somewhat porous fracture, showing in the outer layer groups of yellow stone-cells, and in the inner layer narrow wavy medullary rays, and yields a yellowish-gray powder, which is inodorous and has a slightly bitter, not unpleasant taste.

Constituents.—Three alkaloids have been investigated. *Ditamine* ($C_{16}H_{19}NO_2$, Hesse) is a white bitter amorphous powder, soluble in ether, alcohol, chloroform, and benzene, red with sulphuric acid, violet-red on warming, yellow by nitric acid, dark-green to violet on warming. *Echitamine* ($C_{22}H_{23}N_2O_4$, Hesse), about 1 per cent., is in glossy prisms, containing $4H_2O$, strongly basic, dissolves readily in water, alcohol, and, when freshly precipitated, in ether and chloroform, but is nearly insoluble in benzin and benzene. Its hydrochloride is sparingly soluble in cold water and nearly insoluble in hydrochloric acid and in alkaline chlorides. Sulphuric acid imparts a deep purplish-red color, changing to green. This alkaloid was first called *Ditaine* by Harnack, but this name had already been applied to an impure substance extracted by Gruppe. *Echitenene* ($C_{20}H_{27}NO_4$, Hesse) is amorphous, brown, soluble in alcohol and somewhat in water, reddish-violet by sulphuric acid, purple, afterward green and yellow, by nitric acid. A number of unimportant resinous substances have also been separated and determined.

FIG. 10.

Alstonia scholaris (⅔ Nat.).

Action and Uses.—Alstonia is rarely used in medicine in this country. In those countries in which it is native the drug has been used with success in the treatment of cholera and chronic dysentery. It has also been employed as an antiperiodic, and is said to be an excellent tonic during convalescence from exhausting diseases.

It is given in substance in the dose of from 3 to 5 grains (0.20–0.30 Gm.).

A tincture may be prepared by percolating 3 ounces and 148 grains of coarsely ground root with 1 pint of dilute alcohol (100 Gm. to 480 Cc.), the dose of which is 1 fluidrachm (4 Cc.). Tinctura Alstonia (P. I.—1 in 8), dose 1 to 2 fluidrachms (4–8 Cc.). Infusum Alstoniæ, dose 1 to 2 fluidounces (30–60 Cc.). Extractum Alstoniæ Liquidum, dose 3 to 8 minims (0.20–0.50 Cc.).

Alstonia constricta apparently possesses great antiperiodic and tonic properties. It has been likened to the combined action of quinine and nux vomica.

Other Species.—The genus contains about 30 species, growing in eastern Asia and the Pacific islands.

The closely allied *Poele bark* of Java, which comes from *Alstonia spectabilis* R. Brown, yielded to Hesse 0.8 per cent. of echitamine, or fully 6 times the quantity contained in dita bark; it contains also the other alkaloids in larger proportion than the latter; and in addition thereto *alstonamine*, which resembles ditamine in behavior, but is crystallizable; it was isolated by A. Scharlée in 1862, and then named *alstonine*, but this name is now used for one of the alkaloids of the next.

ALSTONIA BARK, from *Alstonia constricta* F. v. Mueller, a native of Australia, differs greatly in appearance from the dita bark in being 3 to 5 Cm. (1¼ to 2 In.) thick, deeply furrowed, externally brown-gray, or after abrasion ochrey-yellow and ridged upon the inner surface; the bast-layer is about 6 Mm. (¼ In.) thick, yellow, tough and fibrous, and is covered by the thick, spongy, and friable corky layer, which is composed of alternating bands of lighter and darker ochre color, these bands being present also in the much thinner bark from young wood, with a relatively thin periderm; the powder is grayish-yellow, odor slight, taste persistently bitter. The bark was described and its origin determined by Charles Mohr (1879). Palm (1863) found in it a neutral bitter principle, *alstonin;* Hesse (1865), 2 alkaloids *chlorogenine* and *porphyrine;* Mueller and Rummel described an alkaloid, *alstonine;* and Oberlin and Schlagdenhauffen (1879) a second uncrystallizable alkaloid, *alstonicine.* The alkaloids characterized by Hesse in 1881 are: *alstonine* (chlorogenine), $C_{21}H_{20}N_2O_4$, brownish-

yellow, amorphous, readily soluble in alcohol, and, when freshly precipitated, also in chloroform and water, sparingly soluble in ether; its salts are insoluble in dilute acids; *porphyrine* $C_{21}H_{25}N_3O_2$, white, amorphous, soluble in petroleum naphtha, freely soluble in ether, alcohol, and chloroform, the acid solutions of a blue fluorescence: sulphuric or nitric acid dissolves it with a purple color, that with nitric acid changing to yellowish- and brownish-green; *alstonidine* crystallizes from its solutions in chloroform, ether, alcohol, acetone, and hot petroleum naphtha; is not colored by sulphuric or nitric acid, but its solutions show blue fluorescence. One or more other alkaloids are present in minute quantity.

A. VILLOSA Bl., of Java, is also said to contain one or more alkaloids.

ALTHÆA, *U. S.*—Marshmallow.

Radix Hibisci, Radix Bismalvæ.—*White mallow, Wymote, Mortification-root,* E.; *Althee, Eibisch,* G.; *Guimauve,* Fr.; *Altea, Malvabisco,* Sp.; *Malvaisco,* Port.; *Malvavischio,* It.

The dried root of *Althæa officinalis* L. (Fam. *Malvaceæ*), collected from plants of the second year's growth and deprived of the periderm.

Althæa is official in most pharmacopœias, but not in the British. The German calls attention to the bright-yellow coloration of the infusion on treatment with dilute alkalies. Both the entire and the cut root should be free from a coating of chalk or other whitening substance.

The marshmallow plant is a native of Europe and Asia, but the drug is collected from cultivated plants. During the first and second years it consists of a nearly straight tap-root, bearing small rootlets, which in subsequent years develop into large branches, after which the main root is tough and woody and unfit for use. Sometimes the branches are then collected, but are inferior to the tap-root collected in the second year of its growth. Collection is made in the late fall or early winter, the outer bark is peeled off and the root carefully dried.

Description.—Slenderly conical, bearing several broad, shallow furrows, separated by blunt ridges; white externally, marked by brownish, more or less circular scars and fibrous-hairy with partially detached, long bast-fibers; internally yellowish-white, the fracture short and mealy, fibrous in the outer layer; bark occupying about $\frac{1}{10}$ of the radius, containing small groups of bast-fibers in indistinct concentric circles, and separated by a brown cambium from the slightly radiate central cylinder, which has narrow medullary rays and small indistinct vascular bundles of 3 or 4 pitted ducts; there is an abundance of starch in the thin-walled parenchyma. The starch-grains are mostly oval, occasionally indented at one edge, frequently have a simple or branched light band (the cleft hilum) running from end to end, and usually show the rings but faintly. Their polarization is unequal. They are of medium size, commonly about 10, occasionally up to 20, mikrons. There are many large cells filled with mucilage and a few containing crystalline clusters of calcium oxalate. The odor is slight but characteristic; taste sweet, starchy, and mucilaginous.

No substitute for althæa in the entire condition is likely to occur, though old and woody roots and discolored roots whitened with lime or calcium sulphate are commonly seen, and we have even received entire, branched wild roots in an unpeeled condition. All these are readily distinguished. Adulteration of the ground root is very common, almost always with other starchy substances, readily detected by the appearance of the starch-grains. Instead of being marketed in the above-described form, the root is frequently cut up into small cubes, and these are rather more frequently subject to artificial whitening.

Constituents.—A. Büchner reports starch 37 per cent., mucilage 35 per cent., pectin 11 per cent., sugar 11 per cent., fat 1.25 per cent., and asparagin up to 2 per cent. Betaine (*trimethylglycocoll*) was found by Orlow. The gum is said to contain one less water-molecule than that of acacia. The asparagin (*amido-succinamic acid*) is tasteless, and has been called *althein.*

Action and Uses.—Althæa is rarely used in medicine in this country. It possesses certain demulcent properties, and is employed in Europe in inflammatory conditions of the gastro-intestinal and genito-urinary tracts. The bruised leaves in the fresh state and the ground root are occasionally employed as poultices in localized inflammations of the skin. It may be given in infusion (50 Gm. to 1000 Cc. of water) in doses of from 1 to 4 fluidounces (30–120 Cc.), or as the syrup of althæa in the dose of 1 to 4 fluidrachms (4–16 Cc.).

ALUMEN, *U. S., Br., P. G.*—Alum.

Aluminii et potassii sulphas, U. S. 1870.—*Potassium alum, Aluminum and potassium sulphate*, E.; *Alun, Sulfate d'alumine et de potasse*, Fr.; *Alaun, Kalialaun*, G.; *Solfato di alluminia e di potassio*, F. It.; *Alumbre*, Sp.

Formula, $KAl(SO_4)_2 + 12H_2O$ or $K_2Al_2(SO_4)_4 + 24H_2O$. Molecular weight, 471.02 or 942.04.

Alumen, Br.; *Alum, Ammonium alum*, E.; *Alun ammoniacal*, Fr.; *Ammoniak-alaun*, G.

Formula, $(NH_4)_2Al_2(SO_4)_4 + 24H_2O$ or $NH_4Al(SO_4)_2 + 12H_2O$. Molecular weight, 904.42 or 452.21.

It should contain not less than 99.5 per cent. of pure aluminum and potassium sulphate.—U. S.

Origin.—The term alum is a class name given to a number of double sulphates, which consist of a molecule of a sulphate of a univalent metal and a molecule of a sulphate of a trivalent metal crystallizing together with 24 molecules of water, and are represented by the type formula $M'_2SO_4.M'''_2(SO_4)_3.24H_2O$. The name is derived from the oldest and principal member, namely, ordinary potassium alum (alumen). The alums readily crystallize in cubes and octahedra, and resemble one another closely in properties. In the type formula, M' may be K, Na, (NH_4), etc., and M''' may be Al, Cr, Fe, etc. Ordinarily, the name *alum* is indiscriminately used for the alumino-ammonium and for the alumino-potassium alum, both kinds being recognized as such by the British Pharmacopœia, while the United States, French, and German Pharmacopœias recognize the latter only.

The minerals used in the manufacture of alum are *bauxite, cryolite, clay, alum-stone*, or *alunite*, and *alum-slate*. Bauxite is aluminum hydroxide combined with considerable iron, found in rich deposits in Georgia and Alabama, and is a very important raw product for alum-making. *Cryolite* is sodium-aluminum fluoride, extensively employed in the manufacture of sodium hydroxide, whereby aluminum hydroxide is obtained as a by-product, which is worked up into the sulphate or alum. *Clay* is an aluminum silicate. Alum-stone contains aluminum and potassium sulphates and aluminum hydroxide. It yields the purest alum. *Alum-slate* or *schist* consists of a clayey material intermixed with pyrites (iron sulphide) and bituminous matter, and a small quantity of lime, etc.

Preparation.—Various methods are followed according to the raw material used:

1. Alum-stone is first calcined to render the aluminum hydroxide in it insoluble, and then made into piles which are kept moist; after several months the mass becomes disintegrated and converted into alum, which is extracted by water and purified.

2. Bauxite is fused with soda, which gives soluble sodium aluminate, Na_3AlO_3. CO_2 is passed through the solution of this, precipitating aluminum hydroxide, which, when dissolved in sulphuric acid, and mixed with potassium sulphate, forms alum. Cryolite is treated in a similar manner, or is heated directly with sulphuric acid, thus forming sulphate, from which alum is made.

3. Calcined clay moistened with strong H_2SO_4 and allowed to stand some time yields aluminum sulphate, from which alum is obtained as in 2.

4. Alum-slate is allowed to lie in heaps exposed to weather in the air or is slowly roasted by making heaps of alternating layers of slate and wood or coal, and igniting. By the one or other process sulphuric acid is formed from the sulphur in the pyrites, and ultimately aluminum sulphate, which, on lixiviating, is obtained in solution and converted into alum as above.

All alums of commerce are more or less impure, containing variable but small quantities of iron. The variety known as *Roman* or cubical alum is very pure; it crystallizes in cubes, which is an index to the absence of iron. *Roche* alum is a variety named after Rocca, Syria, where it first originated; it occurs in fragments about the size of an almond, of a pale-rose color.

Alum is manufactured on a very large scale, as it finds application in a variety of ways, for example, as a mordant in dyeing industries, in tanning, in preparing colors and lakes, in paper-making, etc., besides its extensive use in medicine.

Properties.—The two official alums are similar in every respect, except that the ammonium alum gives the odor of ammonia on the addition of an excess of potassium

hydroxide or carbonate, and, when heated to full redness, leaves finally alumina. Potassium alum, at a white heat, leaves a mixture of alumina and potassium sulphate.

Alum crystallizes in colorless, inodorous, transparent regular octahedrons, which are usually combined with the cube. Its specific gravity is 1.724—of ammonium alum, only 1.631. It has an acidulous sweetish and astringent taste, and an acid reaction to test-paper. Its aqueous solution dissolves iron, zinc, and other metals which are soluble in diluted sulphuric acid, with the evolution of hydrogen. It is insoluble in alcohol or ether, effloresces slightly on exposure to the air, losing at 40° C. (104° F.) 2.7 per cent., at 47° C. (116.6° F.) 9.6 per cent. of water; when heated to about 92° C. (197.6° F.) it fuses and loses all of its water of crystallization (45.51 per cent.) at 200° C. (392° F.), leaving a voluminous white mass (see Alumen Exsiccatum). Ammonium alum loses all its water of crystallization (47.6 per cent.) above 205° C. (401° F.). At a full red heat both are decomposed, but to effect the complete decomposition of potassium alum a white heat is required, when sulphuric and sulphurous anhydride and oxygen are given off. According to Poggiale (1843), 100 parts of water dissolve at—

	0°	10°	20°	30°	40°	50°	80°	100° C.
Ammonium alum . .	5.22	9.16	13.66	19.29	27.27	36.51	103.08	421.9 parts.
Potassium alum . . .	3.9	9.52	15.13	22.01	30.92	44.11	134.47	357.48 "

The determinations made by Mulder (1864) closely agree with those of Poggiale for ammonium alum, but differ considerably for potassium alum. 1 part of the latter, according to Redtenbacher (1865), dissolves at 17° C. (62.6° F.) in 7.41 parts, and according to Poggiale, at 20° C. (68° F.) in 6.61 parts, and at 10° C. (50° F.) in 10.5 parts of water; this last figure is given by both the British and German Pharmacopœias as the solubility of alum at 15° C. (59° F.), while Mulder's results at the same temperature are 10.9 parts.

The U. S. P. gives the solubility of potassium alum at 25° C. (77° F.) as 1 in 9 parts of water, and in 0.3 part of boiling water; it is also freely soluble in warm glycerin.

Tests.—The alkalies and alkali carbonates precipitate white gelatinous aluminum hydroxide, which is insoluble in ammonia and the carbonated alkalies, but dissolves in an excess of potassium or sodium hydroxide. Commercial alum always contains a little iron, from which it can not be completely freed by recrystallization. It is owing to its presence that solutions of alum become blue on the addition of potassium ferrocyanide, and yield a grayish precipitate with ammonium sulphide. The limit of this impurity is thus ascertained: A solution of 1 Gm. of alum in 20 Cc. of water should not at once assume a blue color on the addition of 5 drops of test-solution of potassium ferrocyanide. —U. S. The German Pharmacopœia requires the same limit. The solution of alum in potassium or sodium hydroxide should not give off the odor of ammonia (absence of more than traces of ammonium alum), nor should 10 Cc. of the aqueous solution (1 in 20), acidulated with 1 Cc. of diluted hydrochioric acid, be colored or rendered turbid by an equal volume of fresh hydrogen sulphide test-solution when kept at 35° C. (95° F.) for at least half an hour (absence of heavy metals). When a saturated solution of alum is shaken with sodium tartrate test-solution, it yields a white crystalline precipitate within half an hour (potassium).

Action and Uses.—Alum is at first sweetish to the taste, and afterward decidedly astringent. Primarily, it excites the flow of saliva, but subsequently materially decreases it. When locally applied to mucous membranes, it whitens and constringes the tissue, and when used upon the skin, thickens and toughens it. It contracts peripheral capillaries and decreases secretion; but if employed indefinitely, it may increase secretion. It has the power of coagulating albumin, and when injected into the blood causes thrombosis and embolism. Small doses of alum frequently cause constipation. Very large amounts produce gastro-enteritis, with vomiting and purging. The drug is only slightly absorbed, but traces of it may circulate in the blood without detriment, and it may be found in the liver and in the urine. Alum was at one time considered a panacea in many conditions, but at present its use in internal medicine has been largely replaced by other more efficacious and agreeable remedies. It is recommended in gastralgia, acute and chronic dysentery, and in diabetes mellitus and insipidus. It may be employed with success in hæmatemesis of a passive character, particularly that resulting from circulatory obstruction or cardiac incompetency. As an emetic, it may be employed

in pseudomembranous croup for the purpose of dislodging the membrane. As it is quite slow in its action, it is not wise to employ this drug for the purpose of emptying the stomach after the ingestion of poisons. Alum may be employed as an antidote in acute lead-poisoning, and in conjunction with opium is of value in the treatment of lead colic. A solution containing 20 grains (1.3 Gm.) in 1 fluidounce (30 Cc.) of water, may be employed in the form of a fine spray in the treatment of hæmoptysis, bronchorrhœa, and chronic bronchitis. Aphonia resulting from laryngeal atony may also be benefited in this way. The various forms of stomatitis are relieved by its use. A gargle containing 1 ounce (30 Gm.) in 8 fluidounces (240 Cc.) of water may be used successfully in the treatment of pharyngitis and tonsillitis; but as this agent has a destructive action upon the enamel of the teeth, it is better to employ a saturated solution upon a swab, or, in the case of follicular tonsillitis, to use the alum stick. A saturated solution is frequently recommended in the treatment of vaginal leucorrhœa resulting from a relaxed condition of the vaginal mucous membrane; and an injection containing from 5 to 10 grains (0.30–0.60 Gm.) to the ounce of water, may be effective in treating chronic gonorrhœa and gleet.

A lotion containing 2 grains (0.12 Gm.) to the ounce of water or dilute alcohol sometimes proves successful in combating the night-sweats of phthisis, and localized sweating of the feet and hands. This lotion is also largely employed for the purpose of preventing bedsores. Because of its great affinity for water and its power of coagulating albumin, dried alum is employed for the destruction of exuberant granulations and the stimulation of indolent ulcers. It is used for ingrowing toenail, a piece of lint or cotton having first been placed between the nail and the granulating surface. Alum in hot concentrated solution is largely employed as a hæmostatic in those conditions where the leaking vessels can be easily reached. In epistaxis and in hemorrhage following tooth extraction its application is usually attended with success.

The alum poultice, made by coagulating white of egg with alum and enclosing the coagulated albumin in a cambric bag, may be beneficial in overcoming recent ecchymosis. The curd obtained by coagulating milk may be employed in the same way.

Internally alum is given in doses of from 5 to 30 grains (0.30–2 Gm.). The emetic dose is from 1 to 2 drachms (4–8 Gm.), given in syrup or warm water. Alum whey is prepared by boiling 2 drachms (8 Gm.) in 1 pint (480 Cc.) of milk, and straining to separate the curd. The dose is 2 fluidounces (60 Cc.).

ALUMEN EXSICCATUM, *U. S., Br.*—Dried Alum.

Alumen ustum, P. G.—*Burnt alum*, E.; *Alun calciné, A. desséché, A. brulé*, Fr.; *Gebrannter Kali Alaun*, G.; *Allume usto*, It.

Formula, $KAl(SO_4)_2$ or $K_2Al_2(SO_4)_4$. Molecular weight, 256.46 or 512.92.

Preparation.—Alum, in small pieces, 100 Gm.; to make 55 Gm. Place the alum in a shallow porcelain capsule, so as to form a thin layer, and heat it on a sand-bath until it liquefies. Then continue the application of a moderate heat, with constant stirring, until aqueous vapor ceases to be disengaged, and a dry white porous mass is obtained, weighing 55 Gm. When cold, reduce the product to a fine powder, and preserve it in well-stoppered bottles.—U. S.

The Br. P. gives the same process, simply adding that the temperature shall not be allowed to rise above 204.4° C. (400° F.).

Properties.—After exsiccation, dried alum forms a light porous mass which is easily rubbed into a white granular powder. It is very slowly (but completely) soluble in cold water, about 17 parts, at 25° C. (77° F.), U. S., 30 parts at 15° C. (59° F.), P. G., but dissolves in a short time in 1.4 parts of boiling water (U. S.), these tests being sufficient to prove its faultless preparation. Owing to its slow solubility, its taste is at first slight, but soon becomes more styptic than that of crystallized alum. *Impurities* may be detected in the same manner as in alum.

Action and Uses.—Dried alum is a powerful astringent and stimulant, and when applied to tissues in process of growth may become escharotic. Hence, as was more particularly pointed out in the preceding article, it is used to repress fungous granulations and stimulate indolent and sanious ulcers, as well as mucous membranes tending to hypertrophy, or throwing off morbid secretions. Powdered dried alum is peculiarly fitted for insufflation.

ALUMINI HYDROXIDUM, *U. S.*—Aluminum Hydroxide.

Alumini hydras, U. S., 1890; *Alumina hydrata*, P. G., 1872; *Argilla pura s. hydrata.* —*Aluminum hydrate, Hydrated alumina*, E.; *Hydrate d'alumine*, Fr.; *Thonerdehydrat*, G.

Formula, $Al(OH)_3$ or $Al_2(OH)_6$. Molecular weight, 77.54 or 155.08.

It should contain not less than 99.5 per cent. of pure aluminum hydroxide.—U. S.

Preparation.—Alum, 100 Gm.; monohydrated sodium carbonate, 43 Gm. Dissolve each salt separately in 1000 Cc. of water, filter the solutions, and heat them to boiling. Then, having poured the hot solution of monohydrated sodium carbonate into a capacious vessel, gradually pour in the hot solution of alum with constant stirring, and add 2000 Cc. of boiling water. Allow the precipitate to subside, decant the clear liquid, and pour upon the precipitate 2000 Cc. of hot water. Again decant, transfer the precipitate to a strainer, and wash it with hot water until the washings produce not more than a faint cloudiness with barium chloride test-solution. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder.—U. S.

Nearly pure aluminum hydroxide is prepared from cryolite. The sodium aluminate obtained in the manufacture of sodium carbonate (see SODII CARBONAS) is treated with milk of lime, resulting in the production of sodium hydroxide and a precipitate of calcium aluminate; on dissolving a portion of the latter in hydrochloric acid, chlorides of aluminum and calcium are formed, and this solution, on being digested with another portion of the precipitate, yields more calcium chloride, which remains in solution, and aluminum hydroxide: $Al_2Cl_6 + Al_2(O_2Ca)_3 + 6H_2O$ yields $3CaCl_2 + 2Al_2(OH)_6$.

On mixing solutions of sodium carbonate and alum a decomposition takes place, resulting in the formation of sodium sulphate, potassium sulphate, aluminum hydroxide, and carbon dioxide: $3Na_2CO_3 + 2KAl(SO_4)_2 + 3H_2O = 3Na_2SO_4 + K_2SO_4 + 2Al(OH)_3 + 3CO_2$. On adding the alkali carbonate to the alum solution, the aluminum hydroxide persistently retains sulphuric acid and alkali; but on slowly adding the alum solution to the alkali carbonate, so that the latter remains continually in excess, only a minute amount of basic sulphate will enter into the precipitate, and will be almost completely decomposed by digesting the latter with the alkaline liquid. In order to obtain it absolutely free from sulphate, Berzelius found it necessary to redissolve the washed hydroxide in hydrochloric acid, and to precipitate this solution with an excess of ammonia. For the washing of the precipitate hot (not boiling) water is directed—a precaution necessary to avoid decomposition of the hydroxide. Sainte-Gille (1855) determined that by prolonged contact with boiling water the hydroxide, $Al_2(OH)_2O_2$, is formed, which is insoluble in dilute acids. Drying the hydroxide at a low temperature leaves it in a smooth condition and prevents it from becoming gritty.

Aluminum hydroxide is occasionally found native, forming the rare crystal mineral *gibbsite*, $Al_2(OH)_6$, of North America, and *diaspore*, $Al_2(OH)_2O_2$, of eastern Europe. It is more frequently found in the ashes of cryptogamous plants than those of phænogams.

Properties.—Aluminum hydroxide is a white, light, amorphous powder, permanent in dry air, odorless and tasteless, and insoluble in water or alcohol; soluble without residue in (dilute) hydrochloric or sulphuric acid, and also in solution of potassium or sodium hydroxide. When heated to redness, it loses 34.0 per cent. of water of hydration.—U. S. A portion of the water is given off at a temperature a little above 100° C. (212° F.), but for expelling the last 10 or 12 per cent. of it a full red heat is required, when *aluminum oxide*, Al_2O_3, is obtained. When added to a turbid or colored liquid the impurities suspended and the coloring-matter contained therein are precipitated; freshly precipitated aluminum hydroxide (*alumine engelée*, Fr.) is best adapted for this purpose; hence its use for the clarification of vegetable juices and the preparation of *lakes*, which consist of aluminum hydroxide united with and tinged by pigments.

Tests.—A solution of 1 Gm. of aluminum hydroxide in 20 Cc. of diluted hydrochloric acid should not at once assume a blue color on the addition of 1 drop of potassium ferrocyanide test-solution (limit of iron), and should not give more than a faint cloudiness with barium chloride test-solution (limit of sulphate). If 1 Gm. of the salt be boiled with 20 Cc. of distilled water, the filtrate should not have an alkaline reaction, and on evaporation should not leave a residue weighing more than 0.005 Gm. (limit of

alkali salts). A solution of the salt (1 in 20) in dilute hydrochloric acid should not yield a color or precipitate with an equal volume of fresh hydrogen sulphide test-solution after standing corked at 35° C. (95° F.) for at least half an hour (absence of heavy metals).—U. S.

Action and Uses.—Aluminum hydroxide may be used as an absorbent and protective in irritations of the skin. Internally it is a mild astringent antacid of some value in the treatment of diarrhœa, due to acidity in the intestine. The dose is from 3 to 6 grains (0.20–0.40 Gm.).

ALUMINI SULPHAS, *U. S.*—Aluminum Sulphate.

Aluminium sulfuricum, P. G.; *Sulfate d'alumine*, Fr.; *Aluminiumsulfat, Schwefelsaure Thonerde*, G.

Formula (crystallized), $Al_2(SO_4)_3 + 16H_2O$. Molecular weight, 625.93.

It should contain not less than 99.5 per cent. of pure aluminum sulphate.—U. S.

Preparation.—Aluminum sulphate, intended for medical purposes, should be made from freshly prepared aluminum hydroxide, which need not be previously dried, by dissolving it in the requisite quantity of diluted sulphuric acid, and crystallizing the resulting solution. Instead of setting the solution aside for crystallization, it may be evaporated on a water-bath to dryness. An excess of acid should be avoided, as well as an excess of the hydroxide; in the event of the latter, basic sulphates are likely to be formed. 100 Gm. of aluminum hydroxide, obtained from 607.33 Gm. of official alum, require 188.31 Gm. of absolute or 203.58 Gm. of official (92.5 per cent.) sulphuric acid to form a normal salt.

Properties and Tests.—Aluminum sulphate occurs as a white, crystalline powder, or shining plates, or crystalline fragments, without odor, having a sweetish and afterward an astringent taste, and permanent in the air. It is soluble in 1 part of water at 25° C. (77° F.), more soluble in boiling water, but insoluble in alcohol. When gradually heated to about 200° C. (392° F.), it loses its water of crystallization (45.7 per cent. of its weight). The aqueous solution of the salt has an acid reaction upon blue litmus-paper. With barium chloride test-solution, the aqueous solution of the salt yields a white precipitate insoluble in hydrochloric acid; and with potassium hydroxide test-solution, a white, gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride test-solution. If 1 Gm. of aluminum sulphate be gently heated with 5 Cc. of potassium hydroxide test-solution, the liquid should not evolve the odor of ammonia. A filtered, aqueous solution of the salt (1 in 10) should not become more than faintly opalescent within 5 minutes after the addition of an equal volume of tenth-normal sodium thiosulphate solution (limit of free acid). The addition of 5 drops of potassium ferrocyanide test-solution to 20 Cc. of the aqueous solution of the salt (1 in 20) should not produce at once a blue coloration (limit of iron). The aqueous solution of the salt (1 in 10), when acidulated with a small quantity of diluted hydrochloric acid, and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen sulphide test-solution, after standing, well stoppered, in a warm place, 35° C. (95° F.), for at least half an hour (absence of heavy metals).—U. S.

For use in the arts, aluminum sulphate is prepared by heating ammonium alum to a dull-red heat, when the ammonium sulphate is decomposed and expelled, leaving anhydrous aluminum sulphate; or it is made from alum-shale and other aluminum silicates, and is known to dyers as concentrated alum or cake-alum.

Action and Uses.—As a remedy in internal medicine aluminum sulphate is rarely employed, and even as a topical application its use is limited. In saturated aqueous solution it may be applied as an astringent and mild caustic to enlarged tonsils, nasal polypi, and cancerous growths, and as a local stimulant to promote the healing of so-called ulcers of the cervix uteri. The addition of benzoin to the solution renders the action of the aluminum sulphate less irritating, but no less efficient, and in this form it is especially useful as an antiseptic and deodorant douche in fetid leucorrhœa. In powder it has been applied for its caustic action to cancerous and other chronic morbid growths.

Benzoinated Basic Aluminum Sulphate, Mentel's Solution, is prepared by dissolving 4 ounces of aluminum sulphate in 8 fluidounces of water, adding precipitated aluminum hydroxide to saturation, and finally 8 drachms of powdered benzoin. Warm to about 65° C. (149° F.) for 6–8 hours and stir occasionally. When the specific gravity has reached 1.26 filter and set aside in a cool place for a week. The solution acquires a balsamic odor and taste and is astringent. Diluted with 30–40 parts of water it is applied to chronic sores and ulcers.

Platt's Chlorides.—A well-known and popular disinfectant, said to be composed of aluminum sulphate, 170; zinc chloride, 40; sodium chloride, 55; calcium chloride, 85; water, 1000.

ALUMINUM—Aluminum.

Alumine, Fr.; *Aluminium*, G.

Symbol, Al. Atomic weight, 26.9.

Occurrence.—The metal aluminum occurs widely and abundantly distributed in nature, but always in combination. Next to oxygen and silicon it is the most abundant element in the solid crust of the earth. It is a constituent of the feldspars, micas, and clays, which occur in such abundance. It also occurs as oxide and hydroxide, and in the mineral *cryolite*, a fluoride of sodium and aluminum.

Preparation.—The metal was first isolated by Wöhler in 1827 by the action of potassium on aluminum chloride. In 1854 St. Claire-Deville obtained it on a commercial scale by heating sodium and the double aluminum sodium chloride, and in the same year Bunsen obtained it by electrolysis of molten aluminum chloride. At the present day nearly all of the metal is made by the action of powerful electric currents on molten mixtures of its compounds; for example, the oxide dissolved in cryolite. Formerly the metal was quite expensive, but it is now so cheap that it may be considered among the common metals. In 1879 a pound cost about 20 dollars, now it is worth from 35 to 40 cents. The chief works for producing aluminum in this country are located at Niagara Falls, and are operated by the Pittsburg Reduction Company. In 1897, 4,000,000 pounds of the metal were produced in this country alone.

Properties.—Aluminum is silvery-white, very malleable and ductile, has a specific gravity of about 2.6, melts at 628° C. (1162.4° F.), conducts electricity well, when pure does not tarnish in air, and approaches iron in toughness. These properties make it a highly useful metal, and it is being employed for many purposes for which iron was formerly used. Most of the metal is used for making alloys. Aluminum bronze is a golden-yellow alloy of 90 per cent. of copper and 10 per cent. of aluminum. Other alloys, containing silver, gold, zinc, iron, chromium, respectively, are made. It is scarcely affected by cold concentrated or dilute nitric or sulphuric acid. Hydrochloric acid and sodium or potassium hydroxide dissolve it with evolution of hydrogen. Acetic acid and phenol act similarly. Solutions of salts in general, but especially of ammonium salts, corrode the metal; hydrogen sulphide does not tarnish it.

COMPOUNDS OF ALUMINUM.

Alumini Acetas.—*Aluminum acetate*, E.; *Acétate d'alumine*, Fr.; *Aluminiumacetat*, G. $Al_2(C_2H_3O_2)_6 + Aq$.—Prepared by dissolving aluminum hydroxide in cold acetic acid; or by decomposing aluminum sulphate with lead acetate, and evaporating at a low temperature, it is obtained as a gum-like mass having an acid reaction and a styptic taste. The solution, heated in the presence of other salts, is decomposed, with the separation of basic aluminum acetate. An impure solution of the salt, containing also potassium or ammonium sulphate, obtained by mixing the aqueous solutions of 6 parts of sugar of lead and 5 parts of alum, and filtering from the precipitated lead sulphate, is extensively employed in dyeing as a mordant and is serviceable as a disinfectant.

Liquor Alumini Acetatis (*Acetici*, P. G.).—*Solution of aluminum acetate*, E.; *Soluté d'acétate d'alumine*, Fr.; *Aluminiumacetat-Lösung*, G.—Dissolve aluminum sulphate 30 parts in water 80 parts; add acetic acid (specific gravity 1.041) 36 parts; triturate calcium carbonate 13 parts with water 20 parts, and add this mixture slowly and with continued stirring to the first solution; set the whole aside for 24 hours without applying heat, and stir occasionally; then strain, press the precipitate without washing it, and filter the liquid. It is a clear colorless liquid, having the specific gravity 1.044 to 1.046, a faint odor of acetic acid, an acid reaction, and a sweetish, astringent taste. On adding to it one-fiftieth of its weight of potassium sulphate and heating it on a water-bath, it coagulates, but after cooling becomes clear again in a short time. The solution is not colored by hydrogen sulphide, and on being mixed with twice its volume of alcohol becomes opalescent, but does not produce a precipitate. On

precipitating 10 Gm. of the solution with ammonia, 0.25 to 0.30 Gm. of alumina should be obtained, proving 7.5 to 8 per cent. of basic aluminum acetate.—P. G. The formula of this compound is $Al_2(OH)_2(C_2H_3O_2)_4$; its molecular weight 323.44. The above process is more simple, and yields more uniform results, than the one devised by Hager (1871), in which aluminum sulphate was decomposed by basic lead acetate.

Alumini Acetotartras.—*Aluminum Acetotartrate*, E.; *Essig-weinsaure Thonerde, Alsol-Athenstädt*, G.—This compound was first prepared by *Athenstädt*, and the process for its manufacture has been patented in Germany. 5 parts of basic aluminum acetate are dissolved in a sufficient quantity of water by aid of 2 parts of tartaric acid, and the solution evaporated to dryness. Or, 100 parts of freshly prepared solution of aluminum acetate are evaporated on a water-bath with 3.5 parts of tartaric acid and finally dried at 30° C. (86° F.) or less on glass plates. It occurs in shining almost colorless amorphous masses, with faint acetous odor and an acidulous astringent taste. It forms with water an acid solution, but is insoluble in alcohol. According to Fresenius, it is a true chemical compound, having the following average composition: Alumina, 23.67; acetic anhydride, 30.77; tartaric acid, 27.17; water, 18.08. The salt has been used in aqueous solution as a non-toxic reliable antiseptic and astringent.

Alumini Betanaphtholdisulphonas.—*Aluminum betanaphtholdisulphonate, Alumnol.* $Al(C_{10}H_6(OH)SO_3)_3$.—A colorless powder, soluble in water and glycerin, slightly soluble in alcohol. Alkalies precipitate $Al(OH)_3$. Albumins and gelatins precipitate it, but excess redissolves it. Astringent and antiseptic.

Alumini Boras.—*Aluminum borate*, $Al_2(B_4O_7)_3$, is made by action of a solution of 11.5 parts of crystallized borax on 6.7 parts of crystallized aluminum sulphate in solution.

Alumini Boroformas.—*Aluminum boroformate*, approximately $(Al_2O_3)(H_3BO_3)(H_2CO_2)$. $5H_2O$, is made by dissolving $Al_2(OH)_6$ in a mixture of 2 parts of formic acid and 1 part of boric acid. Pearly crystals, soluble in water and alcohol. Disinfectant.

Alumini Borotannas.—*Aluminum borotannate, Cutal.*—Solution of 1 part of tannic acid, 4 parts of crystallized borax, in 80 parts of water, poured into 3 parts of crystallized aluminum sulphate in 12 parts of water. Light-brown insoluble powder.

Alumini Borotartras.—*Aluminum borotartrate, Boral.*—1 part of aluminum borate, 1 part of tartaric acid, 9 parts of water. Solution is evaporated to dryness.

Alumini Chloridum.—*Aluminum chloride.—Salzsaure Thonerde*, G., *Chlorure d'alumine*, Fr. Al_2Cl_6.—Prepared pure by passing chlorine over a mixture of Al_2O_3 and carbon at red heat. It forms colorless crystalline masses, giving off hydrochloric acid fumes in moist air. The commercial product contains iron and is yellow. It is used in organic synthesis, in what is known as the Friedel-Crafts reaction. Aluminum chloride in an impure state has been used to some extent. A solution sufficiently pure for disinfecting purposes is obtained by mixing the solutions of 2 parts of alum and 1 part of anhydrous calcium chloride and filtering from the precipitated calcium sulphate. The pure salt, Al_2Cl_6, is best prepared by dissolving aluminum hydroxide in hydrochloric acid and evaporating carefully, when crystals containing $12H_2O$ are obtained, which are readily soluble in water and alcohol and are decomposed by heat. In the anhydrous state, however, aluminum chloride is volatile.

Chloralum, a solution of 20 parts of aluminum chloride in 80 parts of water, containing as impurities lead, copper, iron, calcium, etc. A deodorizer and disinfectant.

Alumini Gallas.—*Basic aluminum gallate, Gallal.*—67 parts of crystallized aluminum sulphate in 500 parts of water, 29 parts of sodium bicarbonate in 500 parts of water, to which add 38 parts of gallic acid; add former to latter solution. Dry precipitate out of light. Brown tasteless powder, soluble in ammonia water, alkalies, hydrochloric and sulphuric acids. Recommended in ozæna.

Alumini Nitras.—*Aluminum nitrate*, E.; *Salpetersaure Thonerde*, G. $Al_2(NO_3)_6.18H_2O$.—The gelatinous aluminum hydroxide obtained from 33 parts of potassium alum or from 31.5 parts of ammonium alum, when dissolved in 20 parts of official nitric acid, yields a solution containing 26 parts of this salt; diluted with water to 260 parts, the solution contains 10 per cent. of the salt, which is with difficulty obtained in deliquescent crystals, soluble also in alcohol.

Alumini Oxidum.—*Alumina, Aluminum oxide*, E.; *Thonerde*, G. Al_2O_3.—This oxide, which is formed when aluminum hydroxide, $Al_2(OH)_6$, is heated to a high temperature, occurs in nature in a variety of forms, all of which are valuable.

Corundum, E., *Corindon*, Fr., *Korund*, G., is a mineral consisting of Al_2O_3. It varies in color, forms rhombohedric crystals, is nearly as hard as diamond, and has the specific gravity 3.9. Transparent varieties of it are the gems *ruby* (*rubis*, Fr., *Rubin*, G.), which is colored red by chromium; the *sapphire* (*saphir*, Fr., G.), which is blue, or if yellow is known as *Oriental topaz*, if green as *Oriental emerald*, and if violet-colored as *Oriental amethyst*. A coarse variety of corundum is known as—

Lapis Smiridis s. Smyris; Emery, E.; *Emeril, Corindon granuleux ferrifère*, Fr.; *Smirgel, Schmirgel*, G.—Its English and French names are derived from Cape Emeri, on the island of Naxos, where the mineral has been mined from ancient times. It is also found in other parts of Europe and in the United States. Owing to its hardness, it is largely employed for cutting and polishing glass, metals, and other hard substances, and is prepared for this purpose by crushing under stampers, sifting, and, for delicate operations, by elutriation. Its color varies between gray, bluish, and brown.

Alumini Paraphenolsulphonas.—*Aluminum paraphenolsulphonate, Sozal.* $Al(C_6H_4(OH)\text{-}SO_3)_3$.—A crystalline powder, soluble in water, alcohol, and glycerin, obtained by solution of $Al_2(OH)_6$ in sulphuric acid. It behaves toward albumin like alumnol. Disinfectant and astringent.

Alumini Salicylas.—*Aluminum salicylate, Salumin* (insoluble). $Al_2(C_6H_4(OH)CO_2)_6.3H_2O$. —A reddish-white powder, insoluble in water, obtained by double decomposition between an aluminum salt and sodium salicylate. Used in catarrh of the nasal passages and pharynx.

Salumin (soluble), obtained by treating insoluble salumin with ammonia water.

Alumini Silicas.—*Aluminum silicate.* Various double silicates of aluminum are known as minerals. The most useful and abundant silicate is *clay*, which is essentially a hydrous aluminum silicate, $Al_4Si_3O_{12}.4H_2O$ or $2Al_2O_3.SiO_2.4H_2O$. Clays are argillaceous or unctuous to the touch, adhere to the tongue, are easily scraped, form a pasty mass with water, may be moulded into forms, and resist high heat. They vary in color, texture, usefulness, etc., according to the impurities present, which usually are iron, calcium, and magnesium compounds, sand, etc. The purest clay is known as *kaolin, fullers' earth*, or *porcelain clay. Bolus* or *bole* is a name that was formerly applied to clays. Different kinds were distinguished: *bolus alba, terra alba, argilla*, is a white nearly pure clay.

Bolus Armena, Bolus rubra, Argilla ferruginea rubra, Armenian bole.—It is reddish-brown in color, due to iron. It was called also *terra sigillata rubra*, because it came into market in cakes bearing a seal.

Terra lemnia, Lemnian bole, is nearly the same as the preceding.

Bolus Veneta, Venetian red, is used in painting.

Creta rubra, Red chalk, Reddle, Rubrica fabrilis.—Deep yellow in color, firm and dense in texture. Used for crayons.

The boles were formerly used in medicines as absorbents and astringents, externally and internally, but are very seldom used now. The only one now found in the shops is Armenian bole, which is used mostly in tooth-powders to give color.

Terra Tripolitana, Tripoli.—Used in scouring metallic surfaces. It is variously colored and does not form a paste with water.

Sienna.—Known in two varieties. *Raw sienna*, a yellowish-brown, smooth clayey body, light in weight and compact. When burnt, it becomes reddish-brown and is known as *burnt sienna*. Both are used in paints. The Italian are the best grades.

Ultramarine. E., Fr.; *Outremer*, Fr.; *Ultramarin*, G., is a pigment which was formerly obtained from *lapis-lazuli* or *lazulite*, a mineral found chiefly in Asia, and composed of sulphur compounds and silicates of aluminum and sodium. The preparation of artificial ultramarine was first made known by C. Gmelin in 1828, and about the same time discovered by Guimet. Shortly afterward it was manufactured on a large scale, and its consumption, which was 3,500,000 kilos in 1862 and 8,500,000 kilos in 1872 (R. Hoffmann), was estimated by R. Wagner in 1880 to be 30,000,000 kilos. It is prepared by heating in crucibles a mixture of clay, sodium sulphate, and charcoal nearly to a white heat for several hours. A white compound is first formed, called *white* ultramarine; this passes into *green* ultramarine, which is employed in the arts to a certain extent, but is mostly converted into *blue* ultramarine, usually by roasting it in the presence of sulphur. By increasing the amount of silica in the first operation the product acquires a more purplish tint, and by treating these products at an elevated temperature with acids *violet* and *red* ultramarines are prepared. All these compounds are decomposed by acetic acid, which does not affect lazulite. Mineral acids decompose them, separating gelatinous silicic acid, sulphur, and hydrosulphuric acid; red ultramarine evolves sulphurous acid gas on being treated with acids. The exact composition is still unknown. Ultramarine blue is largely used for whiting—that is, neutralizing—the yellow tint of sugar, starch, paper, etc.

Alumini Tannas.—*Basic aluminum tannate, Tannal* (insoluble).—Is made by precipitating aluminum sulphate with tannic acid neutralized by ammonia. Insoluble brown powder. Astringent in chronic catarrh.

Tannal (soluble) is made by dissolving the former in tartaric acid and evaporating.

AMARANTHACEÆ.—The Amaranth Family.

Genera about 40, species nearly 500, very widely distributed except in cold countries, especially abundant in tropical America; many species widely distributed as pernicious weeds; economic importance slight, chiefly proteid-nutrient, many species used as pot-herbs, resembling those of the Chenopodiaceæ; many excellent fodder-plants, though not cultivated; some cultivated for ornament; constituents indefinite; none poisonous; none with distinct medicinal properties, though many ignorantly used in native practice as alteratives, as antidotes to snake-bite, etc.

Amaranthus spinosus L., *A. campestris* W., and many other species are used as diuretics. *Euxolus oleraceus* (L.) Moq. (*Amaranthus o.* L.), *Celosia cristata* L., *Ki Kwan* of China, and a few other species are used as astringents in diarrhœa and menstrual disorders. *Euxolus caudatus* (Jacq.) Moq. (*Amaranthus c.* Jacq.), of Africa and Java, *Ærva lanata* (L.) Juss. (*Achyranthes l.* L.), *Æ. tomentosa* Lam., *Kumra-pindi*, etc., of India, and a number of other species are used as anthelmintics.

AMARYLLIDACEÆ.—The Amaryllis Family.

Genera about 70, species about 700, in tropical and subtropical regions, some genera penetrating the temperate zones; highly ornamental, both wild and cultivated. Various species of *Agave* yield leaf-fibers of great use in the arts. Some (*Bomarea edulis* Herb., *Conanthera Simsii* Sweet, etc.) have starchy edible bulbs or rhizomes, while others (*Curculigo stâns* Lab., *Cumingia trimaculata* Don) are rich in mucilage or pectin, for which they are eaten. *Gethyllis Afra* L., of the Cape, yields an edible fruit. Although the family is scarcely known in professional medicine, it is rich in species physiologically active, some of them highly poisonous. The constituents have not been much investigated, but are bitter and probably for the most part glucosidal, though with many alkaloids. From what is known of their action, most of them should be classed physiologically with SCILLA. The following are worthy of special mention:

AGAVE AMERICANA L., the *Maguey* or *Century plant*, most inappropriately called *American aloe*, together with (and apparently for the most part) other species of *Agave*, is one of the most important cultivated vegetable products of the Mexican table-lands. The plant is chiefly propagated by offsets. At about the seventh year, on the average, it becomes of immense size, weighing several, often many hundred pounds and develops a great terminal bud preparatory to flowering. This bud is removed, leaving a cavity in which the watery sap collects. This sap is removed daily for weeks, several tons of it being said to be occasionally collected from a single plant. It may be evaporated to form a crude syrup, and is frequently drunk in the fresh state as a laxative and diuretic, but is usually fermented into the cider-like beverage *pulque*. A spirituous liquor, *mezcal*, of the nature of an impure rum, is also distilled from it. *Agave Virginica* L., of the Southern United States, yields a very bitter root, which is used as an antispasmodic and stomachic.

NARCISSUS PSEUDONARCISSUS L. (*Narcisse des prés*, *Porrillon* or *Gelbe Narcisse*), the common daffodil, native of Southern Europe and largely cultivated, yields an alkaloid, is emetic and poisonous, and has been considerably used in domestic medicine. The genus Narcissus contains some 35 species, more than a dozen of which have been similarly used or reputed poisonous.

Hæmanthus coccineus L., of the Cape of Good Hope, *Crinum Ceylanicum* L., of southeastern Asia, and other species of *Crinum*, have been used as substitutes for squill. *Galanthus nivalis* L. (*Schneeglöckchen*), of southern Europe, *Leucojum æstivum* L., which contains the alkaloids *leucojine* and *leucojitine*, as well as *L. vernum* L., *Hippeastrum Reginæ* Herb., of Brazil, *H. rutilum* Heck., and other species of *Hippeastrum*, *Amaryllis Belladonna* L., and other species of *Amaryllis*, one known in China as *Shau-tsze-kuh* or *Mau-kuh*, *Buphane toxicaria* Herb. (used in southern Africa as an arrow poison), *Crinum Asiaticum* L. (also used as an arrow poison), *Sprekelia formosissima* Herb., *Pancratium maritimum* L., and other species of *Pancratium*, *Hymenocallis tubiflora* Sal., *H. Caribæa* Herb., and several other species of *Hymenocallis*, are all emetics and heart poisons.

AMBRA GRISEA.—Ambergris.

Ambra cinerea.—Ambre, Ambre gris, Fr.; *Amber, Graue Ambra*, G.

Origin.—Ambergris is regarded as a morbid product of the sperm whale, *Physeter macrocephalus* L., and is found in its intestines as well as floating on the sea. One whale has been known to yield 750 pounds of this product.

Description.—It comes in irregular pieces, varying considerably in size, is opaque, of a gray or gray-brown color, with lighter and darker-colored streaks and spots, lighter than water, friable in the cold, but softening when held in the hand. It is of a waxy appearance, fusible in hot water, mixing with melted fats, and soluble in volatile oils, ether, and hot alcohol. It has a peculiar fragrance, is nearly tasteless, and on ignition leaves but little ash.

Composition.—Ambergris consists mainly (about 85 per cent.) of a fatty substance resembling cholesterin, which Pelletier and Caventou have named *ambreïn*. It crystallizes from hot alcohol in white, shining, tasteless, and inodorous needles, which fuse near 35° C. (95° F.). The remaining constituents, according to John (1818), are some balsamic matter, chloride of sodium, benzoic acid (?), and coloring-matter.

Adulterations.—Adulterated and fictitious ambergris can be readily recognized by its different physical properties.

Action and Uses.—Ambergris, like other strongly odoriferous animal products, has been believed to possess a stimulant action upon the nervous and circulatory systems, with a special influence on the generative organs. It was used in low fevers and in spasmodic disorders, especially of the hysterical sort, and often associated with musk, castor, and valerian. It was prescribed in substance in the dose of from 5 to 20 grains (0.3–1.3 Gm.), or more frequently in ethereal solutions. It is seldom if ever employed at the present day as a medicine, but it enters into various perfumes.

Tinctura ambræ of the French Codex is prepared by macerating 10 parts of ambergris, which, according to Stanislas Martin, should be finely powdered by trituration with washed sand, in 100 parts of 80 per cent. alcohol. It is often used for fixing very volatile delicate perfumes.

AMMONIACUM, *Br.*, *P. G.*—Ammoniac.

Gummi-resina ammoniacum or *Doremæ.*—*Ammoniakgummi*, G.; *Ammoniaque, Gomme-resine ammoniaque*, Fr.; *Gomma ammoniaco*, F. It., Sp.

A gum-resinous exudation from *Dorema Ammoniacum* Don. (Fam. *Umbelliferæ*).

Part of the commercial article is believed to come from *D. Aucheri* Boiss, and a distinct, though similar, production comes from *D. robustum* Loftus, both of western Persia.

Origin.—The plant, a tall, stout, naked, and hollow-stemmed perennial, abounds in the deserts of western Asia (see ASAFŒTIDA). Upon the production of the stem, at about the fifth year, the plant fruits and dies. The milky juice exudes, upon insect-puncture, from the stem and flowering branches, and hardens into the tears of commerce. From the base of the stem, among the leaves, there occurs an exudation which turns brown and remains semiliquid. This is often used as a matrix in which more or less of the tears are imbedded to form *cake-ammoniac*, an inferior form. *Drossy ammoniac* is either a similar substance, exuding and becoming mixed with the soil, or artificially so mixed. *Seed-ammoniac* consists of particles about as large as rice-grains or smaller. Sometimes such grains are mixed with the brown mass above mentioned.

Description.—In roundish tears, from 2 to 6 Mm. ($\frac{1}{12}$ to $\frac{1}{4}$ In.) or more in diameter: externally pale yellowish-brown, internally milk-white, brittle when cold, and breaking with a flat, conchoidal, and waxy fracture; or the tears are superficially united into irregular masses without any intervening, dark-colored substance. It has a peculiar odor, and a bitter, acrid, and nauseous taste. When triturated with water, it readily yields a milk-white emulsion.

Ammoniac is official in most pharmacopœias, which give the botanical name variously, as follows: *Diserneston gummiferum* Jaub.; *Heracleum gummiferum* W.; *Peucedanum Ammoniacum* Baill. The Australian admits a purplish-white or milky fracture. The British excludes an alliaceous odor. The Swiss requires that it yield not more than 5 per cent. of ash. Other requirements are that it soften at the heat of the hand; that the freshly fractured surface is colored yellow by solution of potassium hydroxide, and dark-red by solution of chlorinated soda; distinguished from galbanum and asafœtida by not exhibiting a blue fluorescence when a very dilute solution made, after strongly heating in a test-tube, with boiling water, is treated with ammonia solution.

Composition.—The greatest discrepancy exists in statements of the relative percentages of the volatile oil and gum, especially the former, which is placed all the way from $\frac{1}{4}$ to 4 per cent. The discrepancy is probably due in large part to the fact that different methods or degrees of care in the distillation result in the recovery of different products. The oil of the lower percentage yield is described as having a specific gravity of 0.891, and being dextrogyrate and free from sulphur. It has the characteristic odor of ammoniac and is dark-yellow. The amount of resin ranges from 65 to 72 per cent., the moisture about 6 per cent., gum (closely related to acacia) 18 to 26 per cent., and ash, in good samples, not more than 2 to 4 per cent. The resin is partly soluble, partly insoluble in ether. Ammoniac yields no umbelliferon. (For Dieterich's method of ascertaining the acid, resin, and saponification numbers, see *Pharm. Jour.*, June, 1900, page 647.)

African Ammoniac, from *Ferula tingitana* L., is not found in our market. It differs markedly from the official, in that it yields umbelliferon.

Action and Uses.—Ammoniac may be regarded as a circulatory stimulant. In large doses it produces nausea, vomiting, purging, and colicky pains. It has been recommended as an emmenagogue, diuretic, and diaphoretic. The drug may be considered a stimulant to mucous membranes, and has been used in the later stages of bronchitis after the acute inflammatory condition has subsided. In the later stages of gonorrhœa it has been found of value, but on account of its acrid taste is rarely employed.

Locally in the form of the plaster (*Emplastrum Ammoniaci cum Hydrargyro*) it is a mild counterirritant, and has been employed in chronic bronchitis, lumbago, chronic rheumatism, and in pleurisy.

Ammoniac may be administered in the dose of 10 to 30 grains (0.60–2 Gm.), either in pill or as an emulsion.

AMMONII BENZOAS, *U. S.*, *Br.*—Ammonium Benzoate.

Ammoniæ benzoas, Ammonium benzoicum.—Benzoate d'ammoniaque, Fr.; *Ammoniumbenzoat, Benzoësaures Ammonium*, G.

Formula, $NH_4C_7H_5O_2$. Molecular weight, 138.06.

It should contain not less than 98 per cent. of pure ammonium benzoate (C_6H_5-$COONH_4$), and should be kept in well-stoppered bottles.—U. S.

Preparation.—Dissolve benzoic acid in 20 per cent. ammonia water (specific gravity 0.925) by warming and stirring, so that the solution is always alkaline to test-paper. Set aside to crystallize. On evaporating a solution of ammonium benzoate, ammonia is given off; hence to prevent formation of an acid benzoate, the solution should be made alkaline by addition of ammonia water before setting aside to crystallize. The crystals should be dried on filter-paper in the air, and kept in well-closed bottles.

Properties.—Ammonium benzoate crystallizes in colorless or white thin 4-sided hygroscopic laminæ, having a slight odor of benzoic acid, and a saline, somewhat bitter taste, with a slight acrid after-taste; it is readily soluble in alcohol and water, requiring 10.5 parts of water or 25 parts of alcohol at 25° C. (77° F.) and 1.2 parts of boiling water or 7.6 parts of boiling alcohol (U. S.); 6 parts of cold water, 30 parts of alcohol (90 per cent.), and 8 parts of glycerin (Br.). The salt fuses at 193° to 194° C. (379.4°–381.2° F.), with decomposition, and when strongly heated gives off vapors of benzoic acid and ammonia, and finally evaporates without residue. Its neutral solution gives, with ferric salts, a bulky light-yellowish or flesh-colored precipitate, evolves ammonia when heated with potassium hydroxide, and, if it be not too dilute, deposits benzoic acid when acidulated with hydrochloric acid. The acid salt is less soluble, requiring about 60 parts of water and 12 parts of alcohol. Ammonium benzoate gradually loses ammonia in the air and acquires an acid reaction.

Tests.—If diluted nitric acid be added in slight excess to the aqueous solution of the salt (1 in 10), the precipitated benzoic acid, after collecting and washing, should respond to the tests of purity and identity given under Acidum Benzoicum, and the filtrate should not be affected by barium chloride test-solution (absence of sulphate) or by silver nitrate test-solution (absence of chloride). The filtrate from the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should give no color or precipitate when mixed with an equal volume of fresh hydrogen sulphide test-solution after standing corked at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals).—U. S.

Action and Uses.—Ammonium benzoate possesses slight diuretic properties, which are due to the acid radical present (see Acidum Benzoicum). It is employed in phosphaturia and in cystitis resulting from an alkaline urine, and to relieve muscular rheumatism. The salt is more efficient than benzoic acid, inasmuch as the ammonium base is eliminated by the kidney as nitric acid.

The dose is from 10 to 30 grains (0.60–2 Gm.), largely diluted, or given in capsule after meals, and repeated several times daily.

AMMONII BROMIDUM, *U. S.*, *Br.*—Ammonium Bromide.

Ammonium bromatum, P. G.—*Bromure d'ammonium*, Fr.; *Bromammonium, Ammoniumbromid*, G.; *Bromuro di ammonio*, F. It., Sp.

Formula, NH_4Br. Molecular weight, 97.29.

It should contain not less than 97 per cent of pure ammonium bromide, and should be kept in well-stoppered bottles.—U. S.

Preparation.—Ammonium bromide may be prepared by neutralizing hydrobromic acid with ammonia or ammonium carbonate, and evaporating the solution. It may also be obtained by the action of ammonia-water on a solution of ferrous bromide—$FeBr_2 + 2NH_4OH = Fe(OH)_2 + 2NH_4Br$—and filtering off the insoluble ferrous hydroxide;

or, according to Charles Rice (1873), by interaction of equivalent quantities of ammonium sulphate and potassium bromide in boiling strong solution, and when cold addition of alcohol to make about a 15 per cent. solution, which facilitates separation of the potassium sulphate formed: $(NH_4)_2SO_4 + 2KBr = K_2SO_4 + 2NH_4Br$. The bromide obtained by evaporating the filtrate is contaminated with small quantities of ammonium and potassium sulphate. Another method of preparation consists in dropping slowly bromine into ammonia water, 35 parts of bromine to 52 parts of 20 per cent. ammonia water (specific gravity 0.925) and cooling the flask in cold water to moderate the reaction: $3Br + 4NH_3 = N + 3NH_4Br$. The liquid, which should smell decidedly of ammonia, is allowed to stand 2 or 3 days or until a sample does not turn yellow on acidifying with dilute sulphuric acid (absence of bromate), and is then evaporated.

Properties.—The salt occurs as a white granular powder or in prismatic crystals, odorless, neutral to litmus-paper, and having a pungent, saline taste. When pure, it does not become discolored when exposed to light. Impure crystals exposed to light gradually turn yellow and acquire an acid reaction, this change being due usually to iron as an impurity. When heated, it sublimes without melting. It is soluble in 1.2 parts of water and in 12.5 parts of alcohol at 25° C. (77° F.), in 0.7 part of boiling water, and in 9 parts of boiling alcohol (U. S.). Ether dissolves a minute quantity of the salt. Chlorine-water, carefully added so as to avoid an excess, liberates from the aqueous solution of the salt bromine, which dissolves in carbon disulphide or in chloroform with a yellow, reddish-yellow, or yellowish-brown color, which is free from violet tint (iodine).

Tests.—Ammonium bromide may be regarded as pure if, on being heated upon platinum-foil, no residue is left behind. A small portion of the salt placed upon a porcelain tile should not at once acquire a yellow color on the addition of a few drops of diluted sulphuric acid (absence of bromate). 10 Cc. of an aqueous solution of the salt (1 in 20), when acidulated with acetic acid, should not give a turbidity with 1 Cc. of potassium sulphate test-solution (absence of barium), nor should another portion, when slightly acidified with hydrochloric acid, give a color or turbidity with an equal volume of fresh hydrogen sulphide test-solution on standing stoppered at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). 20 Cc. of a 1 per cent. solution (5 per cent., P. G.) of the salt should not at once assume a blue color on addition of potassium ferrocyanide test-solution (limit of iron). If 3 Gm. of the salt be dissolved in water to 100 Cc., then 10 Cc. of this solution, after adding a few drops of potassium chromate test-solution, should require not more than 31.6 Cc. of tenth-normal silver nitrate solution to produce a permanent red color (U. S.). By this titration 3 per cent. of chloride is allowed. 1 Cc. of the silver nitrate solution represents 0.009729 Gm. of NH_4Br, hence for 0.3 Gm. of pure salt, 30.83 Cc. of the silver nitrate would be required. The presence of NH_4Cl in NH_4Br increases the amount of silver nitrate required, because of its lower molecular weight (53.11). If all the NH_4Br were replaced by NH_4Cl, 0.3 Gm. would require for titration 56.48 Cc. of silver nitrate (each Cc. representing 0.005311 Gm. of NH_4Cl)—that is, an excess of 25.65 Cc. over that required for 0.3 Gm. of NH_4Br. This excess represents 100 per cent. impurity of NH_4Cl, hence 0.77 Cc., the excess of 31.6 Cc. of silver nitrate allowed in the U. S. P. titration, over 30.83 Cc., the amount required for absolutely pure NH_4Br, represents 3 per cent. impurity of NH_4Cl in NH_4Br. This calculation holds good only in case the impurity reacting with silver is NH_4Cl. It is not likely, however, to be otherwise. The precipitate of 10 grains of ammonium bromide by sufficient silver nitrate, after washing with water acidulated with nitric acid and drying, will weigh 19.17 grains (1.917 Gm. from 1 Gm. of NH_4Br). The presence of ammonium chloride would increase the weight of the silver precipitate.

According to the British Pharmacopœia, 0.5 Gm. (or 0.3 Gm.) of dried NH_4Br should require not more than 51.8 Cc. (or 31.3 Cc.) nor less than 51.1 Cc. (or 30.66 Cc.) of decinormal silver nitrate solution.

Action and Uses.—Ammonium bromide may be employed in all conditions in which potassium bromide is successfully used unless gastric irritation is present (see POTASSII BROMIDUM). It is a slight stimulant to the circulation, but is not sufficiently powerful to be employed in cardiovascular depression. This salt is irritating to the mucous membranes, and, if given in doses sufficiently large to produce the physiological effects of the bromides, frequently produces gastric irritability. It is stated, however,

that when this drug is combined with other bromides, the combined action is more powerful than that produced by any one of them when administered alone. It may occasionally be given with advantage in epilepsy when some special condition contraindicates the employment of the potassium salt. Ammonium bromide is given in doses of from 10 to 30 grains (0.60–2 Gm.) 3 times daily, largely diluted with water.

AMMONII CARBONAS, *U. S.*, *Br.*—Ammonium Carbonate.

Ammoniæ sesquicarbonas; Ammonium carbonicum, P. G.; *Sal volatile siccum, Alkali volatile.—Volatile salt*, E.; *Carbonate d'ammoniaque, Alcali volatil concret, Sel volatile d'Angleterre*, Fr.; *Ammoniumcarbonat, Kohlensaures Ammon, Flüchtiges Laugensalz, Reines Hirschhornsalz*, G.; *Carbonato di ammonio*, F. It., Sp.

Formula, $NH_4HCO_3NH_4NH_2CO_2$. Molecular weight, 156.01.

It should contain not less than 97 per cent. of a mixture of acid ammonium carbonate and ammonium carbamate, and should yield not less than 31.58 per cent. of ammonia-gas. It should be kept in well-stoppered bottles in a cool place. For dispensing purposes, only the translucent portions should be used.—U. S.

Origin.—Ammonium carbonate was first prepared by Raymund Lully, in the thirteenth century, by the distillation of putrid urine, which contains the normal carbonate, $(NH_4)_2CO_3$, formed from urea, CON_2H_4, and $2H_2O$, water. It was subsequently obtained by the dry distillation of horn, bone, blood, and other animal matters, and for a long time purified by resubliming this crude product in the presence of animal charcoal. In the fifteenth century Basil Valentine observed its production from sal ammoniac and potassium carbonate, in place of which afterward chalk was employed. At present it is largely manufactured by modifications of this process.

Preparation.—A mixture of powdered sal ammoniac with twice its weight of chalk, or of 4 parts each of ammonium sulphate and chalk with 1 part of charcoal, is gradually heated to dull redness in an iron or earthen retort, the vapors being passed through an iron pipe into a leaden chamber, where they condense. The chalk is used in excess to prevent sublimation of undecomposed ammonium chloride, which would otherwise be apt to contaminate the product. It is then purified by resublimation from iron vessels. The reaction results in the formation of calcium chloride (or sulphate) and neutral ammonium carbonate, which on condensation is converted into a salt of the above composition, water and ammonia being given off: $4NH_4Cl + 2CaCO_3$ yield $2CaCl_2 + N_3H_{11}C_2O_5 + NH_3 + H_2O$. The ammonia is utilized either by passing the uncondensed vapors into water or through a cylinder filled with coke which is impregnated with dilute sulphuric acid, resulting in the formation of ammonium sulphate. Barium carbonate may be employed in the place of chalk, and is advantageously used with ammonium chloride, when barium chloride is obtained at the same time. The ammonium salts used being almost exclusively those obtained from coal-gas liquor, the first sublimate contains tarry products, from which it is freed by resublimation.

Properties.—Ammonium carbonate is found in commerce in white crystalline translucent masses, having a strong ammoniacal odor, an alkaline reaction, and a pungent, saline and caustic taste. Exposed to the air, it parts with ammonia and carbon dioxide, becomes opaque, and yields a white powder of acid ammonium carbonate, NH_4HCO_3; this salt is likewise obtained by washing the powdered official carbonate with a little cold water, which dissolves chiefly ammonium carbamate. It is slowly but completely soluble in about 4 parts of water at 25° C. (77° F.), U. S.; in 5 parts of water at 15° C. (59° F.); in 4 parts of water (Br.). It is decomposed by hot water, with the elimination of ammonia and carbon dioxide, and is completely dissipated by prolonged boiling with water. Alcohol dissolves ammonium carbamate, and on being heated yields a sublimate of this salt. The salt should be kept in well-stoppered bottles.

Composition.—The formula given above represents the salt as a compound of 1 molecule of acid ammonium carbonate with 1 of ammonium carbonate from which a molecule of water has been separated. The last-mentioned compound is regarded as the ammonium salt of carbamic acid (which is unknown in the isolated state), and hence is called *ammonium carbamate*, the formula of which is $NH_4NH_2CO_2$. In its pure state this forms tabular crystals, is deliquescent, volatilizes completely at 59° C. (138.2° F.), with decomposition into ammonia and carbon dioxide, and in aqueous solution is soon

converted into normal ammonium carbonate: the solution of the official salt, therefore, contains a mixture of normal and acid ammonium carbonate.

Tests.—Ammonium carbonate should be completely volatilized without charring when heated upon platinum-foil (absence of organic matters and non-volatile salts). It should dissolve in diluted acids without residue, and this solution should be free from empyreumatic odor. 1 Gm. of the salt, on being supersaturated with nitric acid and evaporated to dryness by means of a water-bath, should leave a colorless (white) residue, which at a higher heat volatilizes completely.—U. S., P. G. Empyreumatic products impart a yellow or brown color to the residue. Ammonium thiosulphate, which may be present from decomposition of the sulphate during sublimation, is detected by the brown color produced on adding to the aqueous solution of the salt first an excess of solution of silver nitrate and afterward of nitric acid. After dissolving the salt in a slight excess of diluted nitric acid, it should not be precipitated by barium chloride (sulphate), silver nitrate (chloride). The aqueous solution of the salt (1 in 20), slightly acidified with hydrochloric acid, should not be colored or made turbid by an equal volume of fresh hydrogen sulphide test-solution after being stoppered at 35° C. (95° F.) for at least half an hour, either before or after rendering alkaline with ammonia-water (absence of heavy metals). The presence of ammonium bicarbonate is indicated by the change of the translucent mass into an opaque pulverulent condition. Occasionally the bicarbonate has been observed in translucent solid masses mixed with the official article. In this condition it has but a faint odor of ammonia, and dissolves slowly in water at the ordinary temperature, giving off carbon dioxide.

If 2 Gm. of unaltered, translucent ammonium carbonate be dissolved in a mixture of 50 Cc. each of distilled water and normal sulphuric acid, boiled for a few minutes to expel the liberated carbon dioxide, and then cooled, not more than 12.7 Cc. of normal potassium hydroxide should be required for exact neutralization, litmus test-solution being used as indicator, U. S.; each Gm. should require at least 18.7 Cc. of normal sulphuric acid, Br. Each Cc. of the normal acid solution represents 0.052033 Gm. of the salt. Hence the 37.3 Cc. (50–12.7) of acid required represents 97 per cent. of the pure salt.

Ammonii Bicarbonas, *Ammonium bicarbonate,* NH_4HCO_3, is obtained by treating the powdered official ammonium carbonate with about twice its weight of water, when the bicarbonate will be left as residue, or by keeping the former for two weeks under a bell-glass over sulphuric acid and slaked lime, when the carbamate will evaporate, being decomposed into carbon dioxide, CO_2, and ammonia, NH_3. Ammonium bicarbonate is a white powder, when perfectly dry free from ammoniacal odor, of a cooling, saline taste, insoluble in alcohol, but soluble in 8 parts of water at 15° C. (59° F.); the solution, heated to 36° C. (96.8° F.), begins to give off carbon dioxide. From a concentrated solution clear rhombic prisms of the salt may be obtained. Vogler (1878) ascertained that the salt is not permanent in the air, but is slowly volatilized, with the production of an ammoniacal odor.

Ammonii Carbonas, *Normal ammonium carbonate.* $(NH_4)_2CO_3.H_2O$.—It is obtained by moistening the commercial carbonate with very concentrated ammonia water, letting stand 2 or 3 days in a cool place, and drying the powder quickly between filter paper. It is decomposed quickly in the air into ammonia, water, and bicarbonate. Easily soluble in water, difficultly in alcohol. It is to be distinguished from official *Ammonii carbonas.*

Ammonii Carbamas, *Ammonium carbamate.* $NH_4NH_2CO_2$.—It may be prepared by bringing together dry carbon dioxide and dry ammonia gas, or by passing both into absolute alcohol. It is a crystalline deliquescent powder, smelling strongly of ammonia. Heated to 140° C. (284° F.) in a sealed tube, it yields water and urea, $CO(NH_2)_2$. With water it reacts thus, $NH_4NH_2CO_2 + H_2O + (NH_4)_2CO_3$.

Action and Uses.—Ammonium carbonate is similar to the preparations of ammonia in its action upon the system. When locally applied to mucous membranes, it acts as a decided irritant, and if given by the stomach in overdose causes gastro-enteritis, with burning pain in the œsophagus, stomach, and intestines. Vomiting, purging, spina

convulsions, and collapse may occur. Moderate amounts when given for a long period sometimes produce indigestion, colicky diarrhœa, and emaciation. Ammonium carbonate is a rapidly acting stimulant. It is quickly absorbed from the stomach and intestines, enters the blood, increasing its alkalinity, and is eliminated by the skin, breath, and kidneys. This drug sometimes augments the secretion of the urine and sweat. Ammonium carbonate may be employed in nearly all conditions which demand a rapidly acting stimulant to the heart or respiration. It is employed to overcome surgical shock, especially in children. It may be used during the course of low fevers, in various adynamic conditions, and at the crisis of the acute infectious diseases. Either alone or in combination with ammonium chloride, it is of value in the treatment of the later stages of croupous and catarrhal pneumonia, and in subacute and chronic bronchitis. The atonic stomach of drunkards is also said to be benefited by its use, as it liquefies the mucus covering the viscus and stimulates the glands to normal secretion. Alcoholic intoxication is moderated by its employment. Locally a solution has been used to neutralize the poison of and relieve the pain caused by the bites of insects and venomous serpents. Poisoning by the drug requires the prompt administration of mild acids, such as vinegar or lemon-juice. If convulsions occur, inhalations of amyl nitrite should be employed. The maintenance of bodily heat should not be forgotten. Stimulants such as strychnine and digitalis should be given when indicated.

The dose of ammonium carbonate is from 2 to 10 grains (0.12–0.60 Gm.), best administered in syrup of acacia and water.

AMMONII CHLORIDUM, *U. S.*, *Br.*—Ammonium Chloride.

Ammonium chloratum, P. G.; *Ammonium muriaticum s. hydrochloratum depuratum, Sal ammoniacum, Ammoniæ hydrochloras s. murias.—Purified ammonium chloride, Muriate of ammonia, Sal ammoniac*, E.; *Chlorure d'ammonium, Sel ammoniac, Chlorhydrate d'ammoniaque*, Fr.; *Salmiak, Chlorammonium, Ammoniumchlorid, Reiner Salmiak*, G.; *Cloruro di ammonia*, F. It.; *Clorhidrato de amoniaco*, Sp.

Formula, NH_4Cl. Molecular weight, 53.11.

It should contain not less than 99.5 per cent. of pure ammonium chloride.—U. S.

Origin.—The sal ammoniacum of ancient writers was perhaps in all cases rock-salt. In the eighth century Geber prepared sal ammoniac from urine. Subsequently it was manufactured in Egypt from camels' dung and urine, and exported to Europe, where its manufacture was begun in Venice in the seventeenth century, in Great Britain in 1756, and soon after in Germany and France. At present it is obtained from the products of the dry distillation of bones and other animal matters, and of coal. It is frequently met with in the neighborhood of volcanoes, and is a constituent of several mineral springs, such as Hall, Homburg, Wiesbaden, and others.

Preparation.—The so-called coal-gas liquor is a watery liquid condensed in the preparation and purification of illuminating-gas from coal, and contains principally ammonium carbonate, besides some sulphide, cyanide, and empyreumatic products. The liquor is distilled with lime and the generated ammonia gas is passed into sulphuric acid, forming ammonium sulphate. Most of the gas liquors are now worked up into this salt. By subliming a mixture of the sulphate and sodium chloride, ammonium chloride is formed, $(NH_4)_2SO_4 + 2NaCl = Na_2SO_4 + 2NH_4Cl$. The ammonia gas may also be passed directly into hydrochloric acid to form the chloride.

Any liquid containing ammonia or ammonium carbonate, like the aqueous liquor obtained on the destructive distillation of bones or other animal matter, may be employed in the same manner as coal-gas liquor.

When the crude article is refined by carefully resubliming it, ammonium chloride may be obtained sufficiently pure for medicinal use. Commercial sal ammoniac contains, usually, variable quantities of ferrous and ferric chloride, and should be purified by dissolving 2 parts of it in 3 parts of hot water, adding a small quantity of chlorine water to convert the ferrous into ferric chloride, and afterward ammonia water in slight excess, then filtering the hot solution from the precipitated ferric hydroxide. If the sal ammoniac has been otherwise pure, the filtrate may be evaporated to dryness, and the salt granulated by stirring it continually. If, however, it contains other saline impurities besides the iron, it is best to allow the filtrate to cool, stirring it occasionally, and to

collect the crystalline powder upon a muslin strainer. The impurities will remain in the mother-liquor.

Perfectly pure chloride may be made by bringing together in a suitable apparatus vapors of ammonia and hydrochloric acid, or by neutralizing the pure acid with pure ammonia water. Practically all of the salt used in this country is imported. The *crude* salt, known as sal ammoniac, comes from Calcutta, and is used principally by metal-workers in brazing, to keep surfaces bright; the *refined* salt comes from England.

In chemistry the chloride is the most important ammonium salt, as it is the starting-point for making the various ammonium compounds.

Properties.—Impure ammonium chloride, known in commerce as sal ammoniac, is imported in casks, and consists of colorless or whitish translucent masses which are of a fibrous crystalline structure, very tough and difficult to powder. It is free from odor and has a cooling and strongly saline taste. Its specific gravity is 1.53, and it is soluble in about 3 parts of cold and in little more than its own weight of boiling water. During the solution of the salt in water a considerable reduction of temperature is observed. When the solution is heated with potassium hydroxide or lime ammonia is given off, and when treated with silver nitrate a curdy white precipitate soluble in ammonia is produced. It is less freely soluble in spirituous liquids, requiring 14 parts of boiling alcohol for solution. The salt is permanent in the air, but its solution on being boiled evolves a little ammonia and acquires an acid reaction. At an elevated temperature ammonium chloride evaporates completely without melting, and on cooling is condensed unchanged. Metals which are dissolved by hydrochloric acid are likewise attacked by the hot solution or the vapor of this salt; hence commercial sal ammoniac contains iron, derived from the vessels in which it has been prepared, and its solution turns blue on the addition of potassium ferrocyanide.

Purified ammonium chloride forms a snow-white granular, crystalline powder, the hot solution of which has a faint acid reaction, and does not acquire a bluish-black color by tannin or a blue coloration on the addition of potassium ferrocyanide. It is soluble in 2 parts of water; in 50 parts of alcohol, and in 5 parts of glycerin, at 25° C. (77° F.), and its own weight of boiling water, U. S.; in 3 parts of cold water and 60 parts of alcohol (90 per cent.), Br.

Tests.—The salt should be completely volatilized from platinum-foil (non-volatile salts), and should yield a clear solution with 4 parts of water (absence of barium sulphate, lead salts). The solution, in 20 parts of water, acidulated with hydrochloric acid, should not be affected by an equal volume of fresh hydrogen sulphide test-solution within at least half an hour at 35° C. (95° F.), either before or after adding ammonia-water to slight alkalinity (heavy metals); nor should the neutral solution be affected by ammonium oxalate (calcium), diluted sulphuric acid (barium), barium chloride (sulphate), nor, after acidulating with hydrochloric acid, by ferric chloride; a red color produced with the last test would indicate the presence of sulphocyanate, observed by Warington. The limit of iron, according to the U. S. and P. G., is to be tested by solution of potassium ferrocyanide (10 per cent.), 5 drops of which should not at once produce a blue color if added to 20 Cc. of a 5 per cent. solution of the salt. Empyreumatic and non-volatile impurities may be detected by moistening 1 Gm. of the salt with nitric acid and drying at the heat of a water-bath, when it should not acquire a brown tint, and on heating to a higher temperature the residue should be completely volatilized. If 1 Gm. of the salt be dissolved in distilled water to 100 Cc., then 10 Cc. of this solution should, after adding 5 drops of potassium chromate test-solution, require not less than 18.73 Cc. of tenth-normal silver nitrate solution to produce a permanent color.—U. S. Each Cc. of the silver solution represents 0.005311 Gm. of NH_4Cl.

Ammonii et Ferri Chloridum. *Ammonium chloratum ferratum*, P. G.; *Ferrum ammoniatum; Ammonio-chloride of iron, Ammoniated iron*, E.; *Sel ammoniac martial*, Fr.; *Eisensalmiak*, G.—32 parts of ammonium chloride are mixed with 9 parts of solution of ferric chloride (P. G.), and evaporated with constant stirring to dryness. It is an orange-colored, somewhat deliquescent powder, having a strongly saline and ferruginous taste, and containing 7.25 per cent. of ferric chloride, Fe_2Cl_6, equal to 12.1 per cent. of crystallized ferric chloride or to 2.5 per cent. of metallic iron. It should yield a clear

solution with water, and, being decomposed in the sunlight, should be kept in a dark place.

Because of its disagreeable taste ammoniated iron has been practically discarded. It has received some mention in the treatment of epilepsy, scrofula, and rickets, and especially in those cases in which a marked anæmia exists.

The dose is from 5 to 10 grains (0.30–0.60 Gm.) 3 times daily.

Action and Uses.—Large doses of ammonium chloride irritate the stomach, and cause a burning sensation, which is sometimes followed by nausea and vomiting. It is rapidly absorbed by the stomach and intestines, combines with the blood cells, circulates in the blood, and is eliminated unchanged by all of the mucous membranes, especially those of the lungs and kidneys. Ordinary doses occasionally augment the flow of urine, but in man have no effect upon the central nervous system, respiration, or circulation. Ammonium chloride is employed chiefly for its stimulating effect upon depraved mucous membranes. In the later stages of croupous pneumonia, and in subacute and chronic bronchitis, especially when the mucus is tough, glairy, and ropy, and expectorated with great difficulty, it is one of the best remedies to employ. It increases the flow of and liquefies the mucus, causes desquamation of dead epithelium, and excites the rapid formation of new and healthy mucosa. This drug is also equally valuable in the subacute and chronic gastro-intestinal catarrhs of children, and will often be found of service after all other remedies have failed. It has been recommended in subacute hepatitis, chronic hepatic torpor, hepatic abscess, cirrhosis of the liver, and in catarrhal jaundice, but it is probably most efficacious in the last-named condition. Intercostal neuralgia, trifacial neuralgia, ovarian neuralgia, hemicrania, sciatica, myalgia, and dysmenorrhœa are said to be benefited by its use. It has also been employed with success in the treatment of pyrosis. This remedy has been used with asserted success in the treatment of many glandular enlargements, especially those of the thyroid and prostate glands, but its value in these conditions is questionable. A solution containing 1 ounce (30 Gm.) of the salt in 12 fluidounces (360 Cc.) of water and 4 fluidounces (120 Cc.) of alcohol, may be employed locally in the treatment of senile gangrene. In the above condition it should be used as a fomentation. The same solution is also useful in recent contusions, and in contused and lacerated wounds.

Ammonium chloride is given internally in the dose of from 5 to 20 grains (0.30–1.30 Gm.). As a rule, however, the larger dose is given only to combat neuralgia. It is best administered in a mixture of fluid extract of glycyrrhiza and water, or when employed as an expectorant in *Mistura Glycyrrhizæ Composita*. A spray containing from 10 to 20 grains (0.60–1.30 Gm.) of the salt in 1 fluidounce (30 Cc.) of water is occasionally employed. The fumes may be obtained for inhalation by heating a few grains of the drug in an iron spoon or by means of three bottles, one containing water of ammonia, another hydrochloric acid, and the third water; the first two are connected with the third by glass tubing, and the third is provided with a tube from which the patient inhales. As the vapors pass from the first two bottles into the third, they combine, pass through the water, and any excess either of ammonia or hydrochloric acid which they may contain is in this way prevented from reaching the patient.

AMMONII IODIDUM, *U. S.*—Ammonium Iodide.

Ammonium jodatum.—Iodure d'ammonium, Fr.; *Jodammonium, Ammoniumiodid*, G.; *Yodhidrato de amoniaco*, Sp.

Formula, NH_4I. Molecular weight, 143.83.

It should contain not less than 99.5 per cent. of pure ammonium iodide.—U. S.

Preparation.—This salt is most advantageously prepared by the process recommended by Jacobsen in 1863, which, with some modifications, was adopted by the U. S. Pharmacopœia of 1870. After correcting the errors in the latter this process is as follows: Mix potassium iodide in coarse powder 2½ parts, and ammonium sulphate in coarse powder 2 parts; add to the mixture 2 parts of boiling water; stir well, allow to cool slowly, add 1 part of alcohol, and place the mixture in a bath of iced water, stirring occasionally; throw the mixture into a glass funnel stopped with moistened cotton, collect the clear liquid, and wash the crystalline salt with diluted alcohol; lastly evaporate the

filtrate rapidly to dryness, stirring constantly. Contact with iron or other metals is to be avoided. The two salts interact, forming ammonium iodide and potassium sulphate, which, because of its lesser solubility, crystallizes in great part on cooling and is separated nearly completely by the addition of alcohol. The minute quantity of potassium sulphate contained in the ammonium iodide does not interfere with its medicinal properties. If a still purer salt is desired, the product may be dissolved in alcohol, filtered from the insoluble potassium sulphate, and evaporated as before.

Other processes have been proposed, of which the following may be mentioned: Hydriodic acid is neutralized with ammonia or ammonium carbonate. Ferrous iodide is decomposed by ammonium carbonate, and the filtrate evaporated (Ch. Ellis, 1835). Potassium iodide and ammonium bitartrate are made to react upon each other in hot solutions; on cooling, potassium bitartrate crystallizes, and the evaporated filtrate, still containing a little of this salt, is treated with 70 per cent. alcohol, which dissolves only the ammonium iodide (W. H. Pile, 1862). Iodine is treated with ammonium sulphide until the brown color has completely disappeared, when the solution is boiled, filtered from the liberated sulphur, and evaporated (Spencer, 1852).

When iodine is added to ammonia water, ammonium iodide is produced, but at the same time the extremely explosive compound nitrogen iodide results. Mixtures of the two substances named should therefore be made with great caution.

Ammonium iodide should be preserved in small, well-stoppered vials, protected from light. When deeply colored, it should not be dispensed, but it may be deprived of free iodine by adding to its concentrated aqueous solution sufficient ammonium sulphide test-solution to render it colorless, then filtering, and evaporating on a water-bath to dryness.—U. S.

Properties.—Ammonium iodide is in white granular crystals, and on the slow evaporation of its solution, which should be kept slightly alkaline by ammonia, is obtained in colorless and inodorous cubes having the specific gravity 2.498. If the air is excluded, the salt sublimes undecomposed when heated; in contact with the atmosphere it acquires a yellowish-brown color and a slight odor of iodine. The salt is very deliquescent, and dissolves freely in water and alcohol, requiring 0.6 part of water and 9 parts of alcohol at 25° C. (77° F.), 0.43 part of boiling water, and 3.7 parts of boiling alcohol for solution (U. S.); the solutions have a slight acid reaction and become yellow on exposure. Iodine is liberated on addition of nitric acid, and ammonia by addition of potassium hydroxide or lime. On the addition of a little chlorine-water to the aqueous solution of the salt, iodine is set free, which will dissolve in chloroform or in carbon disulphide with a violet color, and will impart a blue color to mucilage of starch; excess of chlorine will prevent these color-reactions through the formation of colorless compounds.

Tests.—The purity of the salt is recognized by its complete volatility, and by its solution yielding not any, or only a slight, turbidity with barium chloride (sulphate). Ammonium bromide and chloride are recognized by precipitating the solution with silver nitrate and adding ammonia water in excess, in which silver iodide is very sparingly soluble, so that the ammoniacal liquid will yield merely a slight turbidity on the addition of nitric acid. If a precipitate occurs, this is agitated with chlorine water gradually added in the presence of chloroform, which will be colored red if bromine be present; if the chloroform is not colored, the impurity is a chloride. The limits of impurities are thus ascertained: 10 Cc. of a 5 per cent. solution, when acidified with hydrochloric acid, should not be rendered turbid by 1 Cc. of potassium sulphate test-solution (absence of barium). Another portion of this solution, when treated with hydrogen sulphide solution as directed under Ammonii Chloridum, should not be affected (absence of heavy metals). If 0.25 Gm. of the salt be dissolved in 5 Cc. of ammonia-water, then shaken with 19 Cc. of decinormal silver nitrate solution, and the filtrate be supersaturated with 5 Cc. of nitric acid, no cloudiness should make its appearance within 10 minutes (absence of more than about 0.5 per cent. of chloride or bromide). A 1 per cent. aqueous solution should not at once be colored blue by test-solution of potassium ferrocyanide (limit of iron), nor, after being agitated with 1 Cc. of chloroform, should the latter assume a violet color (limit of free iodine).—U. S. The solution of 10 grains of ammonium iodide, treated with sufficient silver nitrate, yields a precipitate of silver iodide, which, after washing and drying, weighs about 16.2 grains (or 1.618 Gm. from 1 Gm. of NH_4I).

Action and Uses.—Ammonium iodide is employed both internally and externally as an alterative. It may be used in all conditions in which potassium iodide (see

POTASSII IODIDUM) is of service. It is to be remembered that while the ammonium base is less depressing to the circulation, it is much more irritating to mucous membranes, and if given in large doses is apt to cause gastric irritability, It has been employed internally in the treatment of scrofulosis, syphilis, gout, and chronic rheumatism. An ointment containing from 20 to 40 grains (1.30–2.60 Gm.) of the drug in 1 ounce (30 Gm.) of lard is recommended in the treatment of scaly affections of the skin, such as psoriasis, lepra, tinea capitis, and those arising from syphilitic infection. A 10 per cent. solution of the salt in glycerin locally applied to enlarged tonsils, particularly if the enlargement is due to struma, is frequently attended with benefit.

Ammonium iodide, or any preparation containing it, should be excluded from light and air, as it is easily decomposed. The ordinary dose of this salt is from 3 to 5 grains (0.20–0.30 Gm.), but as much as 20 grains (1.30 Gm.) can be tolerated by the stomach in some cases.

AMMONII SALICYLAS, *U. S.*—Ammonium Salicylate.

Ammonium salicylicum.—Salicylate d'ammoniaque, Fr.; *Ammoniumsalicylat, Salicylsaures Ammon.*, G.

Formula, $NH_4C_7H_5O_3$ or $C_6H_4(OH)CO_2NH_4$. Molecular weight, 153.94.

It should contain not less than 98 per cent. of pure ammonium salicylate, and should be kept well stoppered and protected from heat and light.

Preparation.—The salt may be prepared by dissolving 10 parts of salicylic acid in 12 parts of 10 per cent. ammonia-water. The solution, which should be slightly acid, is then evaporated to dryness. A colorless crystalline powder or satiny needles are obtained.

Properties.—The salt is odorless and has at first a slightly saline, bitter taste, with a sweetish after-taste. It is permanent in dry air, soluble in 0.9 parts of water and 2.3 parts of alcohol at 25° C. (77° F.), and 1 part of boiling alcohol. When heated the salt fuses with decomposition, emitting inflammable vapors and an odor of phenol, and is finally completely volatilized. The concentrated aqueous solution should be colorless, and it should redden blue litmus-paper.

Tests.—The tests for impurities and for salicylic acid may be found under Sodii Salicylas. Ammonia may be tested for by the methods given under any of the ammonium salts.

Action and Uses.—Ammonium salicylate is considered less depressing than any of the other salts of salicylic acid. It is probably more irritating to mucous membranes than the others, and should be given with caution when repeated large doses are needed. It may be employed in those conditions in which salicylic acid (see Acidum Salicylicum) is beneficial, and it has been especially recommended by Wood in the treatment of rheumatic fever. This drug has also been used with some success as a stimulating expectorant in the later stages of bronchitis.

The ordinary dose of ammonium salicylate is from 2 to 10 grains (0.12–0.60 Gm.), repeated as occasion demands. Larger amounts than the above dose frequently cause gastric irritability.

AMMONII VALERAS, *U. S.*—Ammonium Valerate.

Ammonii valerianas, U. S. 1890.—*Ammonium valerianate*, E.; *Valérianate d'ammoniaque*, Fr.; *Ammoniumvalerianat, Baldriansaures Ammon.*, G.; *Valerianato de amoniaco*, Sp.

Formula, $NH_4C_5H_9O_2$. Molecular weight, 118.24.

It should contain not less than 98 per cent. of pure ammonium valerate, and should be kept in well-stoppered bottles.—U. S.

Preparation.—The practical details of the process recognized by the U. S. Pharmacopœia of 1870 were published by B. J. Crew (1860), and are based upon Chevreul's observations that concentrated valerianic acid, placed in an atmosphere of ammonia, yields this salt in crystals. A convenient quantity of valerianic acid (specific gravity 0.935) is placed in a tall, narrow glass vessel and saturated with dry ammonia gas, which is generated from a mixture of equal weights of ammonium chloride and slaked lime, the gas being dried by passing it through a bottle filled with pieces of burned lime. On the

combination of the dry ammonia gas with the acid much heat is produced, and after neutralization has been attained the salt crystallizes readily on cooling; after several hours the mass is broken into pieces, drained, if necessary, in a glass funnel, dried on bibulous paper, and preserved in a well-stoppered bottle. Valerianic acid which is weaker than the above and of higher specific gravity yields few or no crystals by this process.

Properties.—Ammonium valerate, thus prepared, forms colorless or white quadrangular plates having the odor of valerianic acid and possessing a sharp and sweet taste. It effloresces when placed in a dry atmosphere, and deliquesces in moist air. On the application of heat, it fuses, giving off ammoniacal and acid vapors, and is finally dissipated without residue. It dissolves freely in water and alcohol, the solutions being neutral and on evaporation acquiring an acid reaction from the loss of ammonia. Alkalies decompose it with the evolution of ammonia, and the stronger acids with the separation of oily valerianic acid, floating upon the aqueous solution. Should the salt have an acid reaction, its solution, when dispensed, should be neutralized by the careful addition of ammonia, whereby the disagreeable odor and taste of valerianic acid are masked to a considerable extent. The commercial salt very often has an acid reaction, due to decomposition and loss of ammonia.

Tests.—Heated to redness upon platinum-foil, the salt should leave no residue (potassium, etc., salts). If a neutral solution of the salt be completely precipitated by ferric chloride test-solution, the filtrate should not possess a deep-red color (absence of acetate). The aqueous solution (1 in 20), when slightly acidified with hydrochloric acid and filtered through a small, wetted filter, should not be affected by an equal volume of fresh hydrogen sulphide test-solution after being corked at 35° C. (95° F.) for at least half an hour, either before or after making alkaline with ammonia.—U. S.

Action and Uses.—The spinal cord is slightly stimulated by small doses and depressed by large doses of ammonium valerate. The salt is chiefly used in the nervous manifestations occurring during pregnancy and in hysterical women. It is probable that its virtue depends more upon the mental impression made by the disagreeable and lasting odor of the drug rather than upon any direct physiological action which it possesses. It has been recommended in chorea, epilepsy, and in other clonic convulsions, but its administration in these conditions is of little value.

The dose of ammonium valerate is from 2 to 10 grains (0.12–0.60 Gm.), usually given in the form of the elixir (see Elixir Ammonii Valerianatis, N. F.).

OTHER AMMONIUM SALTS.

Ammonii Acetas, *Ammonium acetate.* CH_3COONH_4.—The salt cannot be prepared by evaporating its solution, as it volatilizes with the water vapor and is also broken up. It is prepared by saturating glacial acetic acid as free as possible from water with dry ammonia gas. It forms colorless crystalline masses, melting at 89° C. (192.2° F.). Very easily soluble in water and alcohol. It is hygroscopic, and should be kept in bottles with paraffined corks. Because of its deliquescent properties, ammonium acetate is rarely employed in medicine except in solution (see Liquor Ammonii Acetatis).

Ammonii Arsenas, *Ammonium arsenate.* $(NH_4)_2HAsO_4$.—Obtained by saturating a concentrated solution of arsenic acid with ammonia water or the carbonate, and evaporating spontaneously. The crystals have an alkaline reaction, and lose half their ammonia on exposure to the air. It has been recommended in stubborn skin affections.

Ammonii Biboras, *Ammonii boras, Ammonium borate.* $(2NH_4HB_2O_4).3H_2O$.—Obtained by dissolving 1 part of boric acid in 3 parts of warmed ammonia water, specific gravity 0.96, and allowing to cool slowly. Semitransparent crystals, with alkaline taste and reaction, efflorescing and losing ammonia in air, soluble in 11 parts of water. Highly recommended in calculus, renal colic, and chronic catarrh of the bladder. Dose 10–20 grains (0.60–1.30 Gm.) in liquorice water every hour.

Ammonii Borofluoridum, *Ammonium borofluoride.* NH_4BF_4.—A salt of hydroborofluoric acid, HBF_4, which is formed when gaseous boron fluoride, BF_3, is brought into water. Used as an antiseptic, by inhalation, in all infectious diseases of the nose and throat.

Ammonii Camphoras, *Ammonium camphorate,* a salt of camphoric acid, $C_8H_{14}(COOH)_2$.—White soluble crystals. A nerve sedative, dose 1 to 3 grains (0.06–0.20 Gm.).

Ammonii Embelas, *Ammonium embelicum, Ammonium embelate.* $C_9H_{13}O_2NH_4$.—A brick-red powder, soluble in dilute alcohol. It is said to be an efficient anthelmintic. Dose 3 grains (0.2 Gm.) for children, 8 grains (0.5 Gm.) for adults.

Ammonii Fluoridum, *Ammonium fluoride.* NH_4F.—Small prismatic crystals, stable in air, obtained by subliming a mixture of 1 part of NH_4Cl and 3¼ parts of NaF in a platinum crucible. Used in decomposition of silicates; to prevent butyric and lactic fermentation in spirit manufacture; in medicine, chiefly in enlargement of the spleen, also as antipyretic. Dose beginning with 5 drops, increased to 30 drops of a solution 4 grains to the ounce.

Ammonii Glycerophosphas, *Ammonium glycerophosphate.* $C_3H_5(OH)_2OPO(ONH_4)_2$.—A translucent salt of glycerophosphoric acid, and used for the same purpose (see under Acida).

Ammonii Molybdas, *Ammonium Molybdate.* $(NH_4)_6Mo_7O_{24}+4H_2O$.—Large colorless prisms, obtained by dissolving molybdic oxide ("acid"), MoO_3, in ammonia water and crystallizing. By precipitating the solution with alcohol, normal ammonium molybdate is obtained, $(NH_4)_2MoO_4$, in small unstable prisms. The salt is a valuable reagent in the laboratory for detecting alkaloids and phosphoric acid. With the latter in nitric acid solution it gives a fine yellow insoluble precipitate, ammonium phosphomolybdate, $(NH_4)_3PO_4.12MoO_3.6H_2O$.

Ammonii Nitras (U. S. 1890), *Ammonium nitrate, Ammonium nitricum, Nitrum flammans.* NH_4NO_3.—For preparing ammonium nitrate, nitric acid is neutralized with ammonia water or ammonium carbonate, or, in place of the latter, the pulverulent bicarbonate which accumulates in the shops may be advantageously employed; the solution is concentrated by evaporation and crystallized, or until it congeals on cooling. On the large scale it is manufactured from ammonium sulphate and potassium nitrate, the mixed solutions of which yield, first, crystals of the less freely soluble potassium sulphate, afterward crystals of ammonium nitrate, which require to be purified by recrystallization. Ammonium nitrate crystallizes in colorless hexagonal prisms, or on the rapid refrigeration of the concentrated solution in long, flexible, thread-like needles; after fusion it forms colorless crystalline inodorous masses. It has the specific gravity 1.70, and possesses a sharp, bitterish taste. It deliquesces in contact with moist air, and dissolves at ordinary temperatures in about half its weight, and in much less of boiling water. It dissolves in 20 parts of alcohol at 15° C. (59° F.), and in 3 parts of boiling alcohol. The solutions on exposure or on heating lose ammonia and acquire an acid reaction. The salt deliquesces in ammonia gas, forming a solution in liquefied ammonia, as observed by Divers (1872). When rapidly heated, it is decomposed into water, nitrogen trioxide, and nitrogen, or into nitrous and nitric oxides, ammonium nitrite, and ammonia; but if gradually heated, it is decomposed into water and nitrous oxide, or *laughing gas,* N_2O. This decomposition is effected according to the following equation: $NH_4NO_3 = N_2O + 2H_2O$. It is evident from this that in the preparation of nitrous oxide gas to be used for inhalation the heat should be carefully regulated and the gas passed through solutions of potassium hydroxide (or lime water) and ferrous sulphate, whereby all the gaseous impurities, except the nitrogen which may be present, are completely removed, even if chlorine should have been evolved in consequence of the presence of ammonium chloride in the nitrate. The salt detonates when thrown upon red-hot charcoal or when mixed with powdered charcoal and heated to 170° C. (338° F.). When mixed with sulphuric acid, nitric acid vapors are given off, and potassium or calcium hydroxide evolves ammonia when heated with the aqueous solution. The salt should be completely volatilized without charring when heated upon platinum-foil, and a 10 per cent. aqueous solution acidulated with nitric acid should not be precipitated either by silver nitrate or barium chloride (absence of chloride and sulphate). Ammonium nitrate is rarely employed in medicine. It is stated that its properties are similar to those of potassium nitrate, and that it causes less cardiac depression than the latter drug. It may be given in doses of from 5 to 20 grains (0.30–1.30 Gm.) 3 times daily.

Ammonii Oxalas, *Ammonium oxalate.* $(NH_4)_2C_2O_4.H_2O$.—Obtained by neutralizing oxalic acid with ammonia water and crystallizing. Long, colorless, shining prismatic crystals, soluble in 23.7 parts of water at 15° C. (59° F.). Used as a reagent and test for calcium salts.

Ammonii Persulphas, *Ammonium persulphate,* $(NH_4)_2S_2O_8$, obtained by electrolysis of a saturated solution of ammonium sulphate, $2(NH_4)_2SO_4 = H_2 + (NH_4)_2S_2O_8$. Colorless crystals, stable at 100° C. (212° F.) when dry. When moist, it decomposes slowly, giving oxygen which is strongly ozonized: $(NH_4)_2S_2O_8 + H_2O = 2NH_4HSO_4 + O$. Soluble in 2 parts of water.

Ammonii Phosphas (Br.); *Ammonium phosphate, Ammonium phosphoricum, Diammonium orthophosphate,* E.; *Ammonium Phosphat, Phosphorsaures Ammon,* G. $(NH_4)_2HPO_4$.—The salt may be prepared by adding ammonia water (about 20 per cent.) to phosphoric acid (about 50 per cent.) until a strongly alkaline reaction results, and evaporating to the point of crystallization. Ammonia water should be added occasionally to preserve the alkaline reaction, in order to avoid the formation of monophosphate, $NH_4H_2PO_4$. The crystals should be quickly dried on filter-paper and placed in a securely stoppered bottle. The salt may also be obtained from bones calcined to whiteness by the process for sodium phosphate (which see), if the sodium carbonate there directed is replaced by ammonium carbonate. If necessary, the salt obtained is to be purified by recrystallization from distilled water, with the addition of a little ammonia, until the crystals are free from sulphate. If the crystallizing liquid should have been rendered excessively alkaline by ammonia, the salt would consist of or contain tri-ammonium (the so-called basic) orthophosphate, of the formula $(NH_4)_3PO_4$. By boiling solutions of di- or tri-ammonium phosphate until ammonia ceases to come off, mono-ammonium phosphate is formed on crystallization. Ammonium phosphate crystallizes in transparent, colorless, monoclinic prisms having the specific gravity 1.678 (Buignet, 1861). It has a cooling and sharply saline taste, effloresces superficially in a damp atmosphere through loss of ammonia, is insoluble in alcohol, but dissolves in 4 parts of water at 15° C. (59° F.) and in 0.5 part of boiling water, yielding a solution which is at first slightly alkaline, but on exposure becomes neutral through loss of ammonia, and by continued boiling loses one-half of it. The solution yields a yellow precipitate with silver nitrate, soluble in nitric acid and ammonia, and evolves ammonia when heated with potassium hydroxide. The salt, when heated, fuses and

is gradually decomposed into metaphosphoric acid, ammonia, and water, and at a bright-red heat is completely volatilized. 2 Gm. of the salt, dissolved in water and precipitated by a solution of ammonio-magnesium sulphate, yield a crystalline precipitate, which, when well washed with diluted ammonia water, dried, and ignited, weighs 1.68 Gm. (Br.). The solution should not be affected by ammonium sulphide, or, after being acidulated with nitric acid, by hydrogen sulphide (absence of metals), and should yield no precipitate with barium chloride (sulphate) or silver nitrate (chloride). 10 grains of the salt, gradually heated upon platinum-foil to redness, should leave a residue weighing 6.1 grains. Ammonium phosphate has never been employed to any extent in medicine. It was first introduced as a remedy in the treatment of rheumatism and gout, but probably has no distinct advantages over the other alkaline preparations employed for these conditions. It is also recommended in the treatment of diabetes resulting from a gouty or lithæmic diathesis. Ammonium phosphate is given in doses of from 10 to 30 grains (0.60–2 Gm.), dissolved in water, 3 times daily.

Ammonii Picras, *Ammonium picrate, Ammonium carbazotate.* $C_6H_2(NO_2)_3ONH_4$.—Obtained by neutralizing picric acid, 1 part in 8 parts of water, with ammonia water, in hot solution, and adding 8 parts of alcohol. On cooling, small orange-colored needles form. It is very bitter, and stains organic bodies permanently yellow; for example, silk, hair, skin, and nails. It precipitates most alkaloids as picrates from their salts. It is used chiefly in preparing histological staining fluids.

Ammonii Silicofluoridum, *Ammonium silicofluoride.* $(NH_4)_2SiF_6$.—Ammonium salt of hydrosilicofluoric acid, H_2SiF_6 (see under Acida). An antiseptic in infectious diseases of throat and nose. It is said to be effective in diabetes, gout, and tuberculosis.

Ammonii Sodii Phosphas, *Ammonium sodium phosphate, Microcosmic salt.* $(NH_4)NaHPO_4.4H_2O$.—Obtained by the alchemists by evaporation of ammoniacal urine. May be prepared by crystallizing a mixture of disodium and mono-ammonium phosphates, as transparent prisms. When heated, ammonia and water escape, leaving a molten bead of $NaPO_3$, sodium metaphosphate, which, like the borax bead, has the property of dissolving metallic salts with characteristic colors. Hence it is a useful salt in qualitative chemical analysis.

Ammonii Succinas, *Ammonium succinate.* $C_4H_4O_4(NH_4)_2$.—Colorless crystals, soluble in water. Specific in cramp colic.

Ammonii Sulphas, *Ammonium sulphate, Ammonium sulphuricum; Schwefelsaures Ammon, Ammoniumsulfat,* G. $(NH_4)_2SO_4$.—Ammonium sulphate was observed by Libavius (1595), and first prepared from oil of vitriol and volatile alkali by Glauber (1667), after which time it was much employed as a purgative. The salt is a constituent of a few minerals, and is sometimes found in the neighborhood of volcanoes. Ammonium sulphate is largely obtained from coal-gas liquor (see Ammonii Chloridum) by mixing it with lime, and distilling off the ammonia and catching it in sulphuric acid. Most of the salt obtained thus is used as fertilizer. In England, about 200,000 tons are made annually from the gas liquors, shale distilling, and coke burning; in Germany about 100,000 tons, and in France 35,000 tons. In this country about 20,000 tons are made yearly. Crude ammonium sulphate is impure, often containing sulphocyanate, NH_4CNS, which is injurious to plants, and therefore depreciates the value of the sulphate as a fertilizer. A pure sulphate for chemical purposes is manufactured by neutralizing pure diluted sulphuric acid with ammonia water and crystallizing. It forms colorless rhombic prisms isomorphous with potassium sulphate, free from odor, and of a sharp saline and bitterish taste. It has the specific gravity 1.76, fuses at 140° C. (284° F.), and is decomposed at a heat exceeding 260° C. (500° F.), yielding ammonia, water, nitrogen, and a sublimate of ammonium sulphite with a little ammonium sulphate. It is soluble in 1.3 parts of water at 15° C. (59° F.) and in 1 part of boiling water. The solution in cold water has a neutral reaction to test-paper, but on exposure or on boiling evolves a little ammonia and acquires a faint acid reaction (Debbits, 1872). It is insoluble in absolute alcohol, requires for solution about 500 parts of alcohol (specific gravity 0.88), but dissolves more freely in weaker alcohol. Its solution evolves ammonia when heated with potassium or calcium hydroxide, and barium chloride produces in it a white precipitate insoluble in diluted nitric acid. When gradually heated to redness the salt should not be blackened, and should finally leave no residue upon platinum-foil. Metals, chlorides, and other impurities are detected in the same manner as in other ammonium salts. Ammonium sulphate is never employed in medicine; it is used in the manufacture of other ammonium preparations.

Ammonii Uras, *Ammonium (acid) urate.* $C_5H_3N_4O_3(NH_4)$.—Obtained by adding an excess of ammonium chloride to a solution of uric acid in 10 per cent. caustic alkali and digesting in a warm place for some time, then allowing to stand a day in a cool place. A granular, crystalline, white, odorless, nearly tasteless powder, soluble in about 1600 parts of cold water.

AMYGDALA AMARA, *U. S.*—Bitter Almond.

Bittere Mandeln, G.; *Amandes amères,* Fr.; *Almendra amarga,* Sp.; *Amendoas amargas,* Port.; *Mandorle amare,* It.

The ripe seed of *Prunus Amygdalus amara* DC. (*Amygdalus communis* L.—Fam. *Rosaceæ*).

Bitter almond is official in most pharmacopœias. The Portuguese requires the seed to be preserved in the shell until needed, an unnecessary precaution, since, if kept with ordinary care, there is little deterioration—not enough to compensate for the inconvenience. Bitter almonds should be kept unbroken and in a dry atmosphere, to prevent the decomposition of amygdalin and of the fixed oil.

FIG. 11.

Bitter almond.

Origin.—The generic identity or distinction of *Prunus* L. and *Amygdalus* L. has long been a bone of contention. The present tendency of systematists is to regard them as distinct.

The almond is probably native of western Asia, but is now cultivated in many subtropical regions. It has the habit of a peach-tree. The fruit is like a peach, but the sarcocarp is thinner, leathery, and dehiscent, leaving the unshelled almond as the equivalent of a peach-stone. The seed, removed from this shell or endocarp, is the official article.

Description.—About 25 Mm. (0.98 In.) long, oblong-lanceolate, flattish, covered with a cinnamon-brown, scurfy testa, marked by about 16 lines emanating from a broad scar at the blunt end. The embryo has the shape of the seed, is white, oily, consists of 2 plano-convex cotyledons, and a short radicle at the pointed end, and has a bitter taste.

When triturated with water, bitter almond yields a milk-white emulsion, which emits the odor of hydrocyanic acid.—U. S.

Almonds, the embryo of which has become discolored or acquired a rancid odor and taste, or has been partly converted into gum (bassorin), as described by Vulpius (1878), are unfit for medicinal purposes.

Adulteration is chiefly with the cheaper sweet almond (especially the Valencia variety) and with peach-seeds. Owing to the existence of several varieties of the bitter, and many of the sweet, no absolute rule for the distinction of the two by their general appearance can be stated, though commonly the bitter variety is shorter, broader, thinner or more flattened, slightly less plump and darker than the sweet. The flavor will, of course, immediately determine any suspected seed. In the ground condition, the adulteration can be detected only by the determination of the percentage of amygdalin. Peach-seeds are readily distinguished by their much smaller size. An artificial almond has been reported in European commerce, consisting chiefly of glucose and scented with nitrobenzol, which bears a remarkably close resemblance to the genuine.

Constituents.—The brown testa contains (Ludwig and Scheitz) tannin, a green resin, and a bitterish, acrid yellow substance (glucoside?). Preserved in dilute alcohol for several days they become covered with minute crystals of asparagin (Portes). The kernel contains fixed oil (*Oleum Amygdalæ Expressum*) about 46 per cent., mucilage 3 per cent., sugar (chiefly glucose, some saccharose) 6 per cent., proteids 24 to 30 per cent., amygdalin (the important constituent) 1 to 3 per cent., and ash (chiefly the phosphates of potassium, calcium, and magnesium) 3 to 5 per cent. The two proteids are modifications of vegetable casein (Ritthausen). Both are soluble in cold water; one, *conglutin* or *amandin*, being precipitated by acetic acid, the other, *emulsin* or *synaptase*, together with some inorganic salts, by alcohol. Both act as emulsifying agents in suspending the fixed oil when almonds are triturated with water, but it appears to be the emulsin only which is capable of decomposing the amygdalin into hydrocyanic acid and benzaldehyde (see OLEUM AMYGDALÆ AMARÆ). This change cannot take place in the unbroken seed, since the amygdalin exists in the parenchymatic tissue of the cotyledons, while the enzyme lies in their vascular bundles and in the caulicle. *Amygdalin* ($C_{20}H_{27}NO_{11}$) was discovered by Robiquet and Boutron-Charlard in 1830, by exhausting bitter almonds deprived of their fixed oil, by alcohol, they observing that the residue would not yield oil of bitter almond. Liebig and Wöhler found in 1837 that grape-sugar was also yielded by amygdalin, this being the first discovery of a glucoside. Amygdalin occurs sometimes in an amorphous condition, but as obtained by alcohol from bitter almonds, peach-seeds, etc., it crystallizes with $2H_2O$, this water being expelled at 120° C. (248° F.). It is soluble in about 15 parts of water, has no odor, a bitter taste, and is not poisonous unless decomposed by emulsin. 17 grains of anhydrous amygdalin yield 1 grain of hydrocyanic acid. The seeds yield nearly 1 per cent. of volatile oil and 0.25 per cent. of hydrocyanic acid. On boiling amygdalin with an alkali, it is decomposed into ammonia and *amygdalic acid* ($C_{20}H_{28}O_{13}$), the latter, on being boiled with dilute acids, yielding glucose and *mandelic* or *phenylglycolic acid* ($C_8H_8O_3$ or $C_6H_5.CHOH.COOH$). Amygdalin can also be decomposed by enzymes present in the flours of rye, wheat, peas, and probably of other seeds.

Action and Uses.—The oil of bitter almond, because of its hydrocyanic acid, has been employed in the coughs of phthisis and in the irritative coughs of children. Because of its rapid elimination it is probably of less service than was formerly supposed. The drug should be given in small quantities at first, because of the variable amount of hydrocyanic acid which it contains. The synthetic oil of bitter almond contains no HCN, and is used only for flavoring purposes. The ordinary dose is from $\frac{1}{4}$ to $\frac{1}{2}$ minim (.015–0.025 Cc.).

Other Amygdalin-yielding Seeds.—The seeds of many other plants related to the almond, both in the *Drupaceæ* (peach, plum, apricot, and cherry) and in the *Pomaceæ* (apple, pear, *Eriobtrya*, etc.), contain amygdalin, and can be made to yield hydrocyanic acid and oil of bitter almond. The former class of seeds are marketed on a large scale for this purpose. The product does not probably go usually into pharmaceutical channels, but is found equally good for confectioners' purposes. It is said that apricot seeds have thus very largely replaced bitter almonds in the manufacture of some classes of confectionery. Peach-kernel oil undoubtedly often substitutes that of bitter almonds and there are tests for distinguishing it (see Oil of Bitter Almond).

AMYGDALA DULCIS, *U. S.*—Sweet Almond.

Süsse Mandeln, G.; *Amandes douces*, Fr.; *Almedra dulces*, Sp.; *Amendoas doces, Mido de Amendoas*, Port.; *Mandorle dolce*, It.

The ripe seed of *Prunus Amygdalus dulcis* D. C. (*Amygdalus communis* L.—Fam. *Rosaceæ*).

Official in most pharmacopœias, which usually apply the important safeguard of cautioning against admixture of the bitter variety. The adulteration of sweet almond with bitter almond is not economical, and need not be expected to occur except by accident. The general distinctions have been stated under Bitter Almond. Admixture in the ground condition is at once determined by the odor when water is added. Adulteration of the paste, oil, and similar preparations with those of the peanut is practised upon a large scale. This subject is treated under Oleum Amygdalæ Expressum.

The native home of the sweet is the same as that of the bitter almond, and it is even more widely cultivated, large quantities being now produced in southern California.

Description.—Closely resembling the bitter almond (see Amygdala Amara), but having a bland, sweetish taste, free from rancidity.

When triturated with water, it yields a milk-white emulsion, free from the odor of hydrocyanic acid.

The cultivated varieties of the sweet almond are very numerous, but hardly require consideration here, since they vary but little in composition.

Composition.—The composition of the sweet almond is practically identical with that of the bitter, with the single exception that it contains no amygdalin, yielding therefore no hydrocyanic acid nor oil of bitter almond. It yields from 6 to 10 per cent. more of the fixed oil than does the bitter. The presence of peptone has been fully demonstrated, E. Lemport having obtained 0.25 per cent. from them.

Pharmaceutical Preparations.—Emulsion (Mixture) of Almond, U. S. P.; Syrup of Almond, U. S. P.

Action and Uses.—Sweet almond when made into an emulsion with water forms an excellent vehicle for the administration of other drugs. The fixed oil is a demulcent, and has been employed in irritated states of the upper air-passages, stomach, and intestines. When deprived of the fixed oil, sweet-almond flour forms a useful article of diet for diabetic patients, as the bread prepared from it contains no starch.

The drug is usually administered in the syrup or emulsion, the dose of either being from 1 to 4 fluidrachms (4–16 Cc.). The expressed oil is given in the dose of from $\frac{1}{2}$ to 1 fluidrachm (2–4 Cc.) or more.

AMYLENUM HYDRATUM, *P. G.*—Amylene Hydrate.

Dimethyl-ethylcarbinol, Tertiary amyl alcohol, E.; *Hydrate d'amylène*, Fr.; *Amylenhydrat*, G.

Formula, $2CH_3.C_2H_5.C.OH = C_5H_{12}O$. Molecular weight, 87.43.

Origin.—Of the alcohols corresponding to the general formula $C_5H_{11}OH$, no less than 8 are theoretically possible, and of this number 7 have been actually prepared.

The best known of the amyl alcohols is that produced in the fermentation of grain, potatoes, etc. (see page 129), and designated as isobutyl carbinol. Tertiary amyl alcohol was first prepared by Wurtz.

Preparation.—A mixture of 100 measures each of sulphuric acid, water, and commercial amylene is exposed to a low temperature with frequent agitation; the amyl-sulphuric acid formed is separated after a lapse of 30 minutes, and added to twice its volume of ice-cold water, filtered, and neutralized with milk of lime or solution of sodium hydroxide, after which it is distilled. The distillate is dehydrated with potassium carbonate, and subjected to fractional distillation, the portion being collected which comes over between 100° and 102.5° C. (212° and 216.5° F.).

Properties.—Amylene hydrate is a limpid, colorless, volatile, neutral liquid of peculiar penetrating odor which reminds of camphor and peppermint, and a burning taste; its specific gravity at 15° C. is 0.815 to 0.820, and its boiling-point, when pure, 102.5° C. (216.5° F.); it congeals at —12.5° C. (9.5° F.). It is hygroscopic. It is soluble in 8 parts of water, and miscible in all proportions with alcohol, chloroform, benzin, glycerin, and fixed oils.

Tests.—It should be neutral to litmus, and in solubility, specific gravity, and boiling-point agree with the above. When 2 drops of potassium permanganate test-solution are added to 20 Cc. of a 5 per cent. aqueous solution of amylene hydrate, the solution should not become decolorized within 10 minutes (absence of amyl alcohol, aldehyde, etc.). If ammonium-silver nitrate solution be added to the aqueous solution and the mixture heated for 10 minutes on a water-bath, no reduction to metallic silver should take place (absence of aldehyde).

Action and Uses.—Amylene hydrate acts purely as an hypnotic, but its effect is exercised only in functional insomnia, and not upon that resulting from pain. According to Hannach and Meyer, it at first stimulates the respiration and nervous system, but afterward paralyzes them. It depresses the heart and causes a continuous fall in blood-pressure. If the dose be sufficiently large, the heart's action becomes irregular and cardiac paralysis eventually occurs. This drug causes a great decrease of bodily heat, prevents tissue-waste, and lessens the excretion of urea. It may be employed as a hypnotic in those cases in which paraldehyde is of service, but it is stated to be more rapid and more fleeting in its effect. W. Niersen has used amylene hydrate with success in the treatment of diabetes insipidus, effecting a cure in a few cases and marked improvement in others.

Excessive amounts of this drug cause deep sleep or stupor, slow irregular respiration and slow pulse, great fall of temperature with loss of reflex action, and finally death. This condition should be treated by the application of external heat, and, if need be, artificial respiration. Appropriate stimulants, such as strychnine, digitalis, and atropine, should be promptly given.

As a hypnotic amylene hydrate should be given in doses of from 15 to 60 minims (1–4 Cc.). It is best administered in capsules, but may be given in alcoholic solution.

Allied Compounds.—AMYLENUM, *Amylene, Valerene, Pentene*, E.; *Iso-amylen, Fuselöl-amylen*, G. C_5H_{10}.—This hydrocarbon was first obtained by Balard (1844). It is prepared by mixing equal parts of amyl alcohol and fused zinc chloride in a capacious retort, and, after a few days, subjecting the mass to distillation on a sand-bath. The distillate, treated with fused calcium chloride to remove moisture, is distilled, and the portion coming over between 30° and 40° C. (86°–104° F.) collected. Amylene consists of varying proportions of 2 or 3 isomeric compounds boiling between 32° and 40° C. (89.6°–104° F.), trimethylethylene, besides isopropylethylene, etc. Amylene is a colorless, thin, volatile, highly inflammable liquid, with a disagreeable, cabbage-like odor, and sweetish taste. Its specific gravity at 15.5° C. is 0.660 to 0.670. It boils at 30°–40° C., but is readily polymerized into compounds having higher boiling-points. It should be neutral to wet litmus-paper and have the specific gravity and boiling-point as above.

AMYL HYDRIDE. C_5H_{12}.—One of the lightest liquids known. Contained in the volatile products of petroleum and cannel coal. A thin, colorless, tasteless, highly inflammable liquid, having an agreeable ethereal odor resembling chloroform. Specific gravity 0.626 at 17° C. (62.6° F.), and boiling at 38° C. (100.4° F.). It is soluble in water, but miscible with alcohol, ether, and chloroform. This product has been recommended as an antiseptic. It is never employed as an internal medicine.

PENTAL, *Trimethyl-ethylene, Beta-isoamylene*.—This is a purer form of amylene, and is prepared from amyl alcohol by digestion with zinc chloride for 24 hours and subsequent fractional distillation, or by the interaction of crystallized oxalic acid and amylene hydrate at 60° to 90° C. (140°–194° F.). It is a colorless liquid, very volatile and inflammable, insoluble

in water, and with a mustard-like odor. Its specific gravity is 0.667, and its boiling-point at 38° C. (100.4° F.). Its solubility is similar to that of amyl hydride. Used as a general anæsthetic in dental surgery. 2 to 3 drachms (8–12 Cc.) being sufficient.

AMYLIS NITRIS, *U. S.*—Amyl Nitrite.

Amyl nitris, Br. (U. S. 1890); *Amylium nitrosum*, P. G.; *Amylæther nitrosus.—Amylo-nitrous ether*, E.; *Azotite d'amyl, Ether amylazoteux*, Fr.; *Amylnitrit*, G.; *Etere isoamil nitroso*, F. It.; *Nitrito de amilo*, Sp.

Formula, $C_5H_{11}NO_2$. Molecular weight, 116.24.

A liquid containing about 80 per cent. of amyl (chiefly isoamyl) nitrite, when assayed by the process given below.—U. S.

The British Pharmacopœia defines amyl nitrite as a liquid produced by the interaction of amyl alcohol which has been distilled between 127.7° and 132.2° C. (262° and 270° F.) and nitrous acid, consisting chiefly of isoamyl nitrite, but containing also other nitrites of the homologous series. It requires that a 5 per cent. volume solution of amyl nitrite in alcohol shall yield not less than 6 times its bulk of nitric oxide gas.

Preparation.—The process now generally followed is identical with the one prescribed in the U. S. P., 1890, for the manufacture of ethyl nitrite in the preparation of spirit of nitrous ether, except that amyl alcohol is substituted for common or ethyl alcohol. A mixture of sodium nitrite, amyl alcohol, and diluted sulphuric acid is subjected to distillation in a retort, that portion being collected which vaporizes between 95° and 100° C.; the distillate is well washed with a solution of sodium bicarbonate, dehydrated with fused calcium chloride, and redistilled below 100° C. (212° F.). The reaction occurring is explained by the following equation: $2C_5H_{11}OH + 2NaNO_2 + H_2SO_4 = 2C_5H_{11}NO_2 + Na_2SO_4 + 2H_2O$; theoretically, 138 parts of sodium nitrite and 176 parts of amyl alcohol are capable of producing 234 parts of amyl nitrite; this yield, however, is never obtained, owing to impurities in the amyl alcohol and sodium salt, as well as possible carelessness during the process. Amyl nitrite is a mixture of α-amyl nitrite and β-amyl nitrite. The former is optically inactive, and boils at 97° C. (206.6° F.), while β-amyl nitrite boils at 94° C. (201.2° F.) and shows dextrorotatory power (Dunstan and Williams, *Pharm. Jour. and Trans.*, Dec. 22, 1888, p. 487). Isobutyl nitrite, boiling-point 67° C. (152.6° F.), is a frequent impurity in amyl nitrite.

Properties.—Amyl nitrite is an ethereal liquid, of a yellowish color, neutral reaction, a peculiar fruit-like odor, and a pungent, aromatic taste, very volatile and inflammable. Its specific gravity is 0.865 to 0.875 at 25° C. (77° F.) (U. S.), or 0.870 to 0.880 at 15.5° C. (60° F.) (Br., P. G.). It boils at 96° to 99° C. (204.8°–210.2° F.), and its vapor (specific gravity 4.03), as well as the liquid, when ignited, burns with a fawn-colored, sooty flame. It is insoluble in water, but dissolves in all proportions in alcohols, in ethers, carbon disulphide, benzene, benzin, and other hydrocarbons. It dissolves fixed oils, fatty acids, phosphorus, and a small proportion of sulphur, caoutchouc, and gutta-percha. On exposure to air and light it acquires an acid reaction, and should therefore be preserved in small glass-stoppered vials kept in a cool and dark place. Strong alkali solutions decompose it into amyl alcohol and nitrite of the base of the alkali. The decomposition is accelerated by heat and the presence of alcohol. If it be added drop by drop to potassium hydroxide heated to fusion, potassium valerianate is formed.

Tests.—Amyl nitrite should remain transparent, or nearly so, when exposed to the temperature of melting ice (absence of water).—U. S., Br., and P. G. If 1 Cc. of normal potassium hydroxide solution and 10 Cc. of water be mixed with a drop of phenolphthalein solution, and then shaken with 5 Cc. of amyl nitrite, the red tint of the aqueous layer should still be perceptible (limit of free acid).—U. S. If equal volumes of amyl nitrite and 5 per cent. solution of potassium hydroxide be thoroughly mixed, the aqueous layer should not acquire a deeper tint than pale yellow (limit of aldehyde).—Br. Absence of aldehyde is indicated when a mixture of 1 volume of amyl nitrite, 1.5 volumes of 5 per cent. solution of nitrate of silver, and 1.5 volumes of absolute alcohol, with sufficient ammonia-water added to just redissolve the precipitate, fails to turn brown or discolor on gently warming the mixture. Submitted to distillation, about 70 per cent. passes over between 90° and 100° C. (194° and 212° F.), the bulb of the thermometer not dipping below the surface of the residual liquid.—Br. The U. S. P. gives the following method of assaying the amyl nitrite content of any commercial sample: Transfer 3 Cc. of the amyl nitrite, which has been previously shaken with 0.5 Gm. of

potassium bicarbonate, and carefully decanted, to a tared 100 Cc. measuring flask, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 Cc., and mix thoroughly. Introduce into a nitrometer exactly 10 Cc. of the alcoholic solution (representing $\frac{1}{10}$ of the original quantity of amyl nitrite), followed by 10 Cc. of potassium iodide test-solution, and afterward by 10 Cc. of normal sulphuric acid. When the volume of gas has become constant (within 30 to 60 minutes) note the volume of gas collected. Multiply this volume in cubic centimetres by 4.8, and divide the product by the original weight of the amyl nitrite. At the standard temperature and pressure the quotient will represent the percentage of amyl nitrite in the liquid. The temperature correction is one-third of 1 per cent. of the total percentage just found for each degree—additive if the temperature is below 25° C. (77° F.), and subtractive if it is above 25° C. (77° F.). The barometric correction is four-thirtieths of 1 per cent. for each millimetre; additive if it is above, and subtractive if it is below 760.

The reaction occurring in the above test is shown by the following equation: $C_5H_{11}NO_2 + KI + H_2SO_4 = NO + C_5H_{11}OH + I + KHSO_4$, from which it is seen that 116.24 parts of absolute amyl nitrite will yield 29.81 parts of nitrite oxide gas. 1 Cc. of this gas at 25° C. (77° F.) weighs 0.0012234 Gm., and corresponds to 0.004773 Gm. of amyl nitrite, and as only one-tenth of the original weight of amyl nitrite is used in the assay, the Pharmacopœia directs that the number of Cc. of gas obtained be multiplied by 4.8, and divided by the original weight of the sample, to find the percentage, which is practically equivalent to multiplying by 0.004773 and by 100, and dividing by one-tenth of the original weight. The temperature and pressure corrections, given in the Pharmacopœia, are sufficiently accurate for all practical purposes.

The "Chlorate Method," proposed by Carl E. Smith (*Am. Jour. Pharm.*, June, 1898, 273–285), is based on the method of B. Grützner for the valuation of alkali nitrites. It is readily applied and is capable of greater accuracy than the gasometric method in general use. The details are as follows: Dissolve 5 or 6 Gm. of amyl nitrite in sufficient alcohol to make 100 Cc. Pour into a flask successively 10 Cc. of distilled water, 10 Cc. of a cold aqueous saturated solution of potassium chlorate, and 10 Cc. of the amyl nitrite solution, add 10 Cc. of 10 per cent. nitric acid, stopper the flask quickly, and shake frequently during 30 minutes. Then add 20 Cc. of decinormal silver nitrate solution, shake briskly for a few moments, add 10 drops of ferric ammonium test-solution as indicator, and titrate the excess of silver solution with decinormal potassium sulphocyanate solution without delay. The interaction between the amyl nitrite and potassium chlorate results in the formation of amyl nitrate and potassium chloride; the latter is decomposed by the silver nitrate, forming silver chloride, which is precipitated. Since each Cc. of decinormal potassium sulphocyanate solution used represents a like volume of the silver nitrate solution in excess, the number of Cc. used subtracted from 20 leaves the volume of silver solution precipitated by potassium chloride. Each Cc. of decinormal silver nitrate solution thus precipitated corresponds to 0.0351 Gm. of amyl nitrite.

Carbonic oxide amyl nitrite is amyl nitrite charged with carbonic acid. The preparation is more suitable for inhalation than the plain amyl nitrite.

Action and Uses.—Amyl nitrite produces cyanosis, throbbing in the head, vertigo, staggering, roaring in the ears, hurried and deep or occasionally irregular respiration, increase in the force and rapidity of the heart, decrease in blood-pressure and temperature, and finally complete relaxation. Medicinal amounts depress the motor centers of the spinal cord, and overdoses depress the motor nerves, the sensory centers of the cord, and the muscles. Small quantities stimulate the heart muscle, but moderate doses depress the circulation. It depresses the vasomotor center, the muscular coats of the arteries, and the vagus center. By so doing, it increases the rapidity but not the force of the pulse. Oxyhæmoglobin is converted into methæmoglobin, and the oxygen-carrying power of the blood is decreased. Amyl nitrite first stimulates the respiratory center, but overdoses produce death by respiratory paralysis. After its administration an increased secretion of urine frequently occurs, and transient glycosuria occasionally results: the former condition is said to be due to vascular dilatation in the kidneys, and the latter to a similar condition in the liver. Tissue-waste is probably lessened, and there may be a decrease in the excretion of urea. Normal temperature is lowered because of the vascular dilatation, the decreased oxygenation, and possibly of some effect

upon the centres governing heat-production and heat-dissipation. The drug is rapidly absorbed, and rapidly eliminated by the lungs and kidneys; a part of it, however, is oxidized in the tissues. Amyl nitrite probably has no direct action upon the cerebrum. The confusion, fulness in the head, and occasional convulsions which it causes are usually attributed to vascular dilatation; while the peculiar visual symptoms, such as an object surrounded by a yellow circle, and that again by a blue one, are possibly the result of medullary irritation. After the ingestion of poisonous amounts consciousness usually remains until death occurs.

Amyl nitrite is always employed by inhalation except in those cases in which spasm of the respiratory muscles prevents its administration by inhalation. When such conditions exist, it should be given by hypodermic injection. This drug lends itself to the control of all forms of general and local spasm. It is successfully employed in controlling and preventing the convulsions accompanying hysteria, tetanus, and strychnine-poisoning. Epileptiform convulsions may be relaxed, and, if preceded by an aura, prevented or aborted by its inhalation. It may be employed in puerperal convulsions, but post-partum hemorrhage may result from the uterine relaxation which it not infrequently causes. Infantile convulsion has also been successfully combated by its administration. Minor spasmodic conditions, such as whooping-cough, laryngismus stridulus, spasmodic croup, asthma, dysmenorrhœa, and the convulsive movements occurring in cocaine-poisoning, are all benefited by its employment. Small quantities have been given with asserted success during labor complicated by an over-distended heart and failing right ventricle. Its momentary administration is also valuable in the treatment of sudden cardiac failure, especially that occurring during the administration of an anæsthetic. It is a good drug to employ in the treatment of angina pectoris, as it relieves the arterial spasm and also the pain. This drug has been successfully used in migraine with hemianopsia, and de Schweinitz recommends it also in the treatment of quinine amblyopia.

Amyl nitrite may be administered by the mouth, but is usually given by inhalation or hypodermic injection. The ordinary dose is from 3 to 5 minims (0.20–0.30 Cc.), but as much as 10 minims (0.6 Cc.) may be inhaled without deleterious results. Pearls made of very thin glass containing these amounts may be obtained, and, when needed, crushed in a handkerchief and their contents inhaled.

According to Bals and Broglio, tertiary amyl nitrite is said to possess the same physiological action without the toxic effects of ordinary amyl nitrite. Slight hypnotic properties have also been ascribed to it. The dose is stated to be from 3 to 5 minims (0.20–0.30 Cc.), as required. It is never employed as a hypnotic.

The following derivatives of amyl alcohol are allied to the preceding, and are of interest:

AMYLIS ACETAS.—*Amyl acetate, Oil of pear,* E.; *Amylacetat, Essigsäure-amylester,* G. C_5H_{11}-$C_2H_3O_2$ or $CH_3CO_2C_5H_{11}$.—A fruit ether. 105 parts of amyl alcohol and 130 parts of concentrated sulphuric acid are mixed, and after several days poured upon 100 parts of dry sodium acetate, or 120 parts of potassium acetate, and the mixture submitted to distillation. The distillate, washed with dilute alkaline solution, is dehydrated by means of fused calcium chloride and again distilled. A colorless liquid, of an agreeable pear-like odor. Specific gravity 0.875 at 15° C. (59° F.). Boils at 138° C. (280.4° F.). It is but slightly soluble in water, but is miscible with alcohol and ether. It is a good solvent of some resins. Used as a component of fruit essences and as a solvent of resins in the preparation of lacquers and varnishes.

AMYLIS NITRAS.—*Amyl nitrate.* $C_5H_{11}NO_3$.—It was discovered by W. Hofmann (1848), and is most advantageously prepared, according to Chapman and Smith (1867), by dropping through a long tube, and *with constant stirring,* 50 Cc. of amyl alcohol into 150 Cc. of a mixture made of 1 volume of nitric and 2 volumes of sulphuric acid, and kept cool by ice and table-salt. Without visible reaction an oily layer of amyl nitrate separates on the surface, which is obtained pure by washing with dilute potassium hydroxide solution and water, drying with calcium chloride, and rectifying. It is a colorless oily liquid of a peculiar odor and sweet and burning taste. Its density at 15° C. (59° F.) is 0.902, and it boils at 147° C. (296.6° F.). It dissolves in glacial acetic acid, benzene, and in ethyl, methyl, and amyl alcohol, but not in water. Amyl nitrate is never employed in internal medicine.

AMYLIS SALICYLAS.—*Amyl salicylate,* E.; *Amylsalicylat, Salicylsäure-amylester,* G. $C_5H_{11}C_7$-H_5O_3 or $C_6H_4OHCO_2C_5H_{11}$.—This compound may be prepared by treating a mixture of amyl alcohol, salicylic acid, and sulphuric acid after the manner stated under Methyl Salicylate. It is a colorless, refractive liquid, emitting an odor resembling that of salol, and boiling at 270° C. (518° F.). Amyl salicylate is soluble in alcohol, ether, and chloroform, but is almost insoluble in water. It is preferred by some to methyl salicylate, for internal and external use

in the treatment of rheumatism, and may be given in capsules, in doses of 8 to 10 grains (0.5–0.6 Gm.), 3 times a day.

AMYLIS VALERIANAS.—*Amyl valerianate or valerate, Apple oil*, E.; *Amylvalerianat, Baldriansäure-amylester*, G. $C_5H_{11}C_5H_9O_2$ or $(CH_3)_2CH.CH_2.CO_2.C_5H_{11}$.—A fruit ether. 105 parts of concentrated sulphuric acid and 88 parts of amyl alcohol are mixed, cooled, added to 124 parts of dry sodium valerianate and the mixture distilled on a sand-bath. The distillate is washed with a dilute solution of sodium bicarbonate, dehydrated with fused calcium chloride, and redistilled. A colorless liquid of an agreeable apple-like odor, having a specific gravity of 0.880 at 15° C., and boiling at 188°–190° C. (370.4°–374° F.). Used as a component of fruit essences. Amyl valerianate has been successfully employed in the treatment of gall-stone colic. It is stated that it not only acts as a sedative and aids in the expulsion of the calculus, but that it also possesses the power of dissolving cholesterin. Its employment in renal colic is said to be less satisfactory. The drug is given in doses of from 2 to 3 grains (0.10–0.20 Gm.), usually in capsule, 2 or 3 times daily.

AMYLUM, *U. S., Br.*—Starch.

Corn-starch, E.; *Kraftmehl, Maisstärke*, G.; *Fécule (Amidon) de Maize*, Fr.

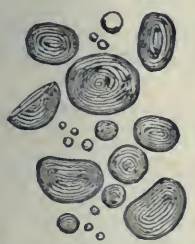
Formula, $C_6H_{10}O_5$. Molecular weight, 161.62.

The starch grains obtained from the fruit of *Zea Mays* L. (Fam. *Gramineæ*).

The maize plant, as well as its grain, is too well known to call for description. It originated in tropical America, and is now cultivated in tropical and warm-temperate regions throughout almost the entire world. Besides its enormous use in the form of meal, it is an important source of glucose and glucose syrup, fixed oil, Bourbon whiskey, alcohol, and starch. The average composition of corn is water 11, starch 55, gum and sugar 3, cellulose 13, gluten 8, fat 4.7, and ash 1.1. The starch is formed by the action of chloroplastids on carbon dioxide and water, in sunlight, in the leaf and other chlorophyll-bearing parts of the plant, first in the form of related saccharine compounds, then dissolved and in this state transported to the growing seed. Here, in the absence of light, it is taken up by amyloplasts, by which it is accumulated in successive layers. These layers, containing water in different proportions, have different refractive powers, thus imparting a stratified appearance to the starch-grain, usually indistinct in corn starch. The nucleus continues to occupy a nearly central position, and is recognized as the "hilum." As the starch-grain matures, several fissures usually radiate from this hilum, imparting to it an irregularly stellate appearance. The grains are at first solitary and rounded in outline, but with growth they become polyhedral by close packing and very commonly cohere in groups of 2 to several, the so-called "compound starch-grain," in the extracted starch. Each starch-grain consists of a thin resistent membrane, enclosing starch-granulose and starch-cellulose, the latter forming an outside layer.

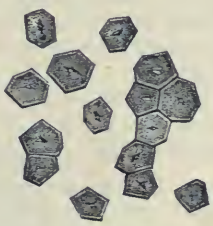
Various methods, differing chiefly in the mechanical details, are followed in the extraction of starch. The "alkaline" or "sweet" process is commonly used in America.

FIG. 12.



Wheat starch.

FIG. 13.



Corn starch.

FIG. 14.

Rice starch.

Each magnified 250 diameters.

The corn is steeped in large tanks until soft, to remove most of the oil and inorganic matter. It is then ground and, with a stream of water, is passed through strainers, the settled matter being stirred for some hours with a solution of caustic soda. The alkali takes into solution the remaining oil and some albuminoid, and precipitates the gluten and other impurities as a dark heavy layer, upon which the white starch subsides. This starch is moulded into blocks, partly dried over porous bricks, and then kiln-dried for 3 to 15 days at 68.8° to 80° C. (156° to 176° F.). Kept at the higher temperature for a short time, it produces the "small pipe" masses or "crystals"; while at the lower temperature, for a longer time, it forms large irregular chunks. It now con-

tains 0.5 to 1 per cent. of moisture, but quickly absorbs up to 15 to 18 per cent. from the air.

Description.—In irregular, angular masses, which are easily reduced to a fine powder; white, inodorous, and tasteless; insoluble in ether, alcohol, or cold water. Under the microscope appearing as granules, nearly uniform in size, averaging about 0.019 Mm. (0.0012 In.), more or less angular in outline, with indistinct striæ and with a distinct hilum near the center.

Triturated with cold water, it gives neither an acid nor an alkaline reaction with litmus-paper.

When boiled with water, it yields a white jelly having a bluish tinge, which, when cool, acquires a deep-blue color on the addition of iodine test-solution.

When completely incinerated, starch should not leave more than 1 per cent. of ash.—U. S.

The Ph. It. limits the loss of moisture at 120° C. (248° F.) to 20 per cent. Starch is official in all pharmacopœias, but there is the greatest diversity in the variety or varieties specified. If pure, there is little difference among them, from a pharmaceutical standpoint, except as to abundance and price. There is, however, considerable difference in the liability to impurity.

Adulteration.—The only object in the selection of corn starch as the official article is to secure an abundant, cheap, and unobjectionable article. Because these objects are so well attained, adulteration is largely excluded. The only serious danger is of adulteration by potato starch, or possibly by sweet potato or yam starch, which two latter are considered toward the close of this article.

Fig. 15.

Potato starch.

Potato starch (Fig. 15) when boiled with acidulated, and to a less extent with pure, water gives off a peculiar and unpleasant, "herbaceous" odor. The paste produced by mixing it with twice its weight of hydrochloric acid is transparent and jelly-like. Its grains float upon chloroform. They are of exceedingly irregular size, the larger and characteristic ones 0.06 to 0.1 Mm. (0.0024 to 0.0039 In.), ovate, the hilum at the smaller end only occasionally stellate or fissured, the rings incomplete, coarse, and strongly marked, so that the appearance of the grain has been compared with that of an oyster shell. The smaller grains are nearly circular.

Pharmaceutical Preparations.—Glycerite of Starch, U. S. P.; Iodized Starch, N. F.

Action and Uses.—In the form of a very fine powder, starch is an excellent remedy for intertrigo or chafing. It may be dusted upon the skin to absorb secretions, and is commonly dusted about the genitals of infants to prevent excoriation.

Internally starch is demulcent and nutritive, and in the form of starch paste, made by boiling it with water, is used in gastro-enteritis and in inflammatory conditions of mucous membranes elsewhere. Starch paste is the best antidote to iodine-poisoning.

Starch water, made by diluting starch paste with water, is an excellent vehicle for the administration of drugs by the rectum.

Starch poultices, made by boiling starch with a sufficient amount of water to make a gelatinous mass, may be employed in chronic skin diseases to aid in the separation of crusts, and are also of value in removing excessive quantities of iodine from the skin.

Other Starches.—Starch (*Stärke*, G.; *Amidon*, Fr.; *Almidon*, Sp.; *Amido*, It.) is the most widely distributed and abundant hydrocarbonaceous reserve food of plants. It may be stored in the most temporary way, that made during the day consumed during the following night, or it may be stored during one season in buds, fleshy rhizomes, tubers, or roots, to provide for the next season's growth, or in seeds for the use of the newly germinated embryo. From this it may be supposed that the sources of commercial starch are numerous. Besides the enormous quantities of many sorts in general trade, many others are extracted upon a smaller scale for local consumption by both civilized and savage peoples. An enumeration of all the plants which have been thus utilized for the extraction of their starch, or for consumption because of its presence, would make a formidable list.

Quite aside from these economic considerations, starch possesses great interest because of its extensive use, or that of substances containing it, for purposes of adulteration or sophistication, an interest that is of special importance to the pharmacist, since it applies so largely to powdered drugs. Since the different starches usually present individual characteristics, they commonly afford evidences of such adulteration, and frequently of its precise nature. This

aspect of the subject is omitted from the present article, but is taken up in connection with the different drugs to which it relates.

The origin, mode of formation, and nature of starch have been indicated in a general way in our account of the official variety. There are, however, numerous general or special deviations from that type. The starch grains may remain single, instead of uniting in groups, as there described. This form will then be free from angular outlines. Their form is subject to the widest variation, as is the degree of flattening, the position and appearance of the hilum, the character and distinctiveness of the rings. The size of the grains must, of course, be non-characteristic in the smaller direction, since they are in different stages of growth, but in their degree of enlargement they are usually subject to a fair degree of definition, so that the upward limit becomes of value in identification. In some plants starch is not in grains, appearing in rod-like forms, or is even amorphous. A small amount may exist in the amorphous state, while most is in granules.

ARROW-ROOT STARCH (Fig. 16) (*Maranta starch; Marantastärke*, G.; *Arroru*, Sp.), from the rhizome of *Maranta arundinacea* L. (Fam. *Marantaceæ*).—This plant is a native of tropical America, and has been largely introduced to cultivation in other tropical countries. Its cultivation is one of the most important industries of the West Indies, especially of Bermuda and St. Vincent, which latter island is said to have exported nearly 21,000 barrels in 1890. It is often known as "Bermuda arrow-root," because at one time chiefly exported from there. Although highly prized and expensive, its qualities differ little from those of other starches. One reason for this preference is doubtless the great care and scrupulous cleanliness observed in its preparation. The name "arrow-root" was derived from the fanciful idea that it was useful as an antidote to arrow poisons. The fresh rhizome yields from 13 to 20 per cent. Because of its high price, this variety is largely subject to adulteration, or even entire substitution, especially by potato, sweet potato, and yam starches (which see). It emits no disagreeable odor when boiled with acidulated water, and the paste produced by mixing it with twice its weight of hydrochloric acid is white and opaque. 1 part with 96 parts of boiling water gives a moderately thin, pellucid mucilage. It occurs either as a powder or in lumps less than ¼ inch in diameter. The most of the grains are shortly and broadly ovate, a few circular, 0.0327 to 0.0375 Mm. (0.00129 to 0.00148 In.) in diameter, hence much more uniform than other starches. The hilum is near the larger end, and is almost invariably fissured or stellate. Viewed under water, the rings are very distinct. The use of arrow-root starch has declined enormously, especially in the United States. That which is known as Florida arrow-root is the starch of the stem of *Zamia integrifolia* Jacq. (coontee or wild sago), produced chiefly in Florida, but also, from this and other species of *Zamia*, in the West Indies. *Talcahuana arrow-root starch*, produced in Chili, is from *Alstræmeria Ligtu* L. (Fam. *Amaryllidaceæ*). *Tahiti arrow-root starch* is from *Tacca pinnatifida* and *T. oceanica* Forst. (Fam. *Taccaceæ*). The grains are of about the size of those of cassava, but are flattened and angular. Used principally as a food for infants and invalids.

FIG. 16.

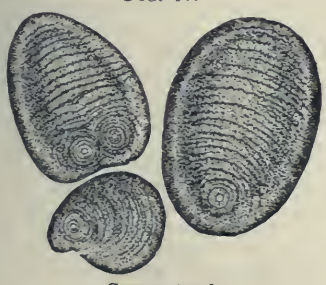
Maranta starch

ARUM STARCH or ARUM ARROW-ROOT (*Amido da Serpentina*), from *Arum Dracunculus* L. (Fam. *Araceæ*), is somewhat like tapioca, but is commonly truncated at two ends, with the hilum eccentric, and rarely exceeding 0.014 Mm. (0.00055 In.) in diameter.

BARLEY STARCH consists usually of very small, angularly circular grains, about 0.0185 Mm. (0.00073 In.) in diameter, but with a few grains reaching to nearly four times this size.

CANNA STARCH (Fig. 17) (*Tous-les-mois, Toulema, Amidon de canne, Fécule de Tolomane, Cannastärke*).—From the rhizome of *Canna edulis* Ker. (Fam. *Cannaceæ*, according to some authors

FIG. 17.



Canna starch.

FIG. 18.

Curcuma starch.

a subfamily of *Marantaceæ*). This showy plant is a native of tropical America, and is considerably cultivated for its starch in the West Indies. Probably other species of the genus contribute part of the product. It is decidedly similar in general characters to arrow-root starch, but its granules are much larger, about the largest in commerce,

measuring 0.0469 to 0.132 Mm. (0.0018 to 0.0052 In.). Three distinct forms are recognized, the smallest ovoid, the intermediate pear-shaped, while the largest are oval-elliptical or sometimes pointed at the ends. The hilum is near one end, almost always circular, and the rings are fine, regular, and incomplete. The grains swell very rapidly in potassium hydroxide solution. Potato starch may be easily mistaken for this, but its polarization is not nearly so regular.

Curcuma Starch (Fig. 18) (*Curcuma arrow-root, East India arrow-root*), from *Curcuma angustifolia* Roxb. (Fam. *Marantaceæ*), possesses elongated triangular or irregularly oval, nearly transparent grains, from 0.0304 to 0.0609 Mm. (0.0012 to 0.00238 In.) in diameter. The rings are distinct but very incomplete, the eccentric hilum faint. Under the influence of potassium hydroxide solution they swell very irregularly, becoming greatly deformed.

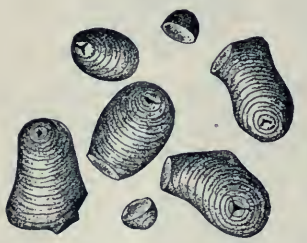
Oat Starch is quite similar to corn starch, irregularly 3- to 6-sided, and 0.0044 to 0.03 Mm. (0.00018 to 0.00118 In.) in diameter.

Potato Starch (*Amylum Solani; Kartoffelstärke*, G.; *Fécule de pomme de terre*, Fr.; *Fecula de Patata*, Sp.; *Amido da Bapata*, Port.), official in the Belgian, Dutch, French, Portuguese, and Spanish Pharmacopœias. From the tubers of *Solanum tuberosum* L. (Fam. *Solanaceæ*). This well-known tuber has the following composition in round numbers: water 13, starch 82, nitrogenous matter 2¼, woody fiber 1, fat ⅕, ash ½, besides some unimportant water-soluble constituents, including nearly ½ per cent. of sugar. The characters of the starch-grains have been given under the adulterants of the official article.

Rice Starch (Fig. 19) (*Amylum Oryzæ; Rice flour; Reisstärke*, G.; *Farine de riz*, Fr.; *Amido do Rizo*, It. and Sw.), from the grain of *Oryza sativa* L. (Fam. *Gramineæ*). Rice is native of India and is cultivated in most tropical and warm-temperate countries. It is the most important food-plant of India, China, and other eastern countries. Its composition is, in round numbers, water 14, nitrogenous substance 7, fat ½, starch 78, ash ½. Its starch-grains are the smallest of any commercial variety, about ⅛ as large as those of maize, 0.005 to 0.0075 Mm. (0.0002 to 0.0003 In.) in diameter, of similar form and very much inclined to be compound. The hilum is usually stellate.

Sago Starch, or *Sago* (Fig. 19), is the product of *Arenga saccharifera* Labill. (*Saguerus Rumphii* Roxb.), the *Areng. Sugar, Condiar*, or *Lantar palm* of the East Indies, *Phœnix farinifera* Roxb., *Cycas circinalis* L., *C. revoluta* Thunb., and other species of *Cycas*, as well as from several species of *Metroxylon* Rottb. Sago is obtained from the pith of the stems of these plants. It exists in commerce in both the raw and prepared forms, the latter having been subjected to partial cooking, which obliterates or obscures the hilum and the rings and makes it somewhat transparent. Obtained as it is from so many different species, it presents marked differences of size and form. In general it may be stated that the grains range from 0.0282 to 0.066 Mm. (0.00111 to 0.0026 In.) and from oval to ovate in form, the hilum circular and at the more rounded end, the opposite end tending to be truncate. The rings are indistinct. The prepared sago is commonly in the form of globules, "Pearl Sago." This form is very frequently only potato or other starch, sold under a fictitious title.

Fig. 19.



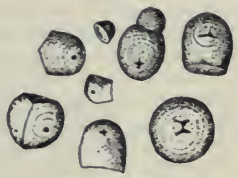
Sago starch.

Sweet Potato Starch, from the tuberous root of *Ipomœa Batatus* Poiret, the sweet potato or camote (Fam. *Convolvulaceæ*), is quite largely manufactured and much used for purposes of adulteration, especially of pepper and other species. Its grains are very large, 0.022 to 0.0352 Mm. (0.0008 to 0.0014 In.), oval in shape, with the hilum near one end and with numerous distinct rings.

Tapioca Starch or Tapioca (Fig. 20) (*Amylum manihot, Cassava starch, Cassavastärke, Brazilian arrow-root, Manihot, Manioca* or *Mandioca starch*), from the tuberous roots of *Manihot Manihot* (L.) Lyons (*Jatropha M.* L., *M. utilissima* Pohl), the *Sweet cassava*, etc., *M. palmata* (Vell.) J. Muell. (*Jatropha p.* Vell., *J. dulcis* Gmel., *M. Aipi* Pohl), the *Bitter cassava*, etc., and occasionally perhaps from other species or varieties (Fam. *Euphorbiaceæ*). These plants are natives of tropical America, where they are enormously cultivated under the names indicated by the above titles for the starch, as well as under the name *Yuca* (not *Yucca*), and where they constitute one of the most important of the food-products. There we have seen them cultivated by savages who had never before seen a white man, and with whom such cultivation must have been original. The plants exhibit many cultivated forms, some of them so striking as to raise the question of their being distinct species. These varieties exhibit different degrees of adaptability to varying climate, from the most humid to the most arid. The plant is, therefore, recommended highly as a famine-food in districts subjected to severe drought. It has been estimated that it will yield 10 tons per acre, and that 1 man can readily till 6 acres. The roots are used in other important ways besides the extraction of the starch. Boiled, fried, baked, or roasted, the sweet variety is a staple article of diet, occupying the place of the potato among us. Grated, dried, and ground into flour, it furnishes a breadstuff scarcely second in local importance to ordinary flour. The bitter variety, after being freed from its hydrocyanic acid by a process of fermentation, is used similarly, and is also used for the extraction of the starch. The tapioca, commonly in yellowish or brownish-white, smoothish, hard grains resembling pebble-stones, is masticated dry at the table as a substitute for bread when this is not obtainable, The unfermented roots of the bitter variety are highly

poisonous. having been found to contain on an average 0.0275 per cent. of prussic acid, distributed throughout the tissue. Sweet cassava contains about half as much, confined chiefly to the rind. Even after cooking, doubtless imperfectly performed, deaths are frequent. Drinking water soon after eating it is said to greatly increase the danger. This, like sago starch, is sold in a natural and a prepared form, though the former is scarce. The latter is usually in irregular flake-like pieces, reminding one somewhat of pieces of popped-corn, very hard and slightly translucent. A "pearl" form is also common and, like pearl sago, is very commonly factitious. The grains of tapioca starch are usually combined in groups. The individual grains measure from 0.014 to 0.0188 Mm. (0.00055 to 0.00075 In.). They are lenticular in form when natural, having the hilum nearly central, angular, cleft or stellate, and the rings coarse and only moderately distinct. In the prepared form, most of them have become altered to the forms shown in the accompanying cut. The Ph. Port. recognizes the value of this starch to such an extent that it directs its use when no particular variety is specified.

Fig. 20.



Cassava starch.

Wheat Starch (Fig. 12) (*Amylum tritici, Midon de ble*, Fr.; *Amido di frumento*, It.; *Almidon de Trigo*, Sp.; *Amido do Trigo*, Port.), from the grain of various species and varieties of *Triticum* L. (Fam. *Gramineæ*), the well-known wheat of cultivation. The composition of this grain is in round numbers water 13½, nitrogenous substances 12½, fat nearly 2, sugar 1½, gum and dextrin 2½, starch 64, fiber 2½, ash 1¾. Its starch is official in all pharmacopœias except that of the United States. It is subject to great adulteration, especially with potato, rye, and corn starch. The detection of potato starch has already been considered. The grains of corn starch are more uniform in size and ⅔ as large, irregularly angular, much inclined to be compound, the layers indistinct, the hilum usually split. Corn starch may also be distinguished by the relative amount of the swelling of the grains in an accurately measured time period in a potassium hydroxide solution of definite strength. A sample of the starch is mixed with 10 Cc. of 1.8 per cent. solution of potassium hydroxide and prevented from settling during 2 minutes. 4 or 5 drops of 25 per cent. hydrochloric acid are then added and the mixture shaken vigorously. The reaction should be alkaline. If examined within a minute, the corn starch will be found unaffected, the wheat starch greatly swollen (*Baumann*). Wheat starch yields no jelly, but, slowly, a strongly opalescent solution when agitated for 10 minutes with a mixture of 2 parts of hydrochloric acid and 1 part of water. The grains of wheat starch are almost circularly lenticular and of extremely variable size, ranging from 0.0022 to 0.052 Mm. (0.00009 to 0.0019 In.). The hilum is indistinct and the rings are moderately so.

Rye Starch is very similar, but contains many more split grains than the wheat.

Yam Starch, from various species of *Dioscorea* (Fam. *Dioscoreaceæ*), is used for the same purpose as sweet potato starch. Its grains are even larger, 0.05 to 0.07 Mm. (0.0019 to 0.0027 In.) ovate, with one end much narrowed, the round (rarely fissured or stellate) nucleus at the smaller end, the rings moderately distinct, the grains frequently in pairs.

ANACARDIACEÆ (TEREBINTHINACEÆ).—The Cashew Family.

Genera about 60, species nearly 600, mostly tropical, a few extending into temperate regions, the juices commonly milky and often intensely irritant cutaneous poisons (see Rhus Toxicodendron); of great economic importance in many directions. Some of the timbers are valuable, owing to their durability and insect-proof qualities, while others, as of *Rhus glabra*, are of great beauty in cabinet-work. Many species are rich in tannin and are used in important ways as astringents (see Rhus glabra, Galla and *Quebracho extract*, under Quercus), others in resins and oleoresins, this property having given one name, "Terebinthinaceæ," to the family (see Mastiche), while many yield beautiful varnishes of the Japanese lacquer type (see Rhus Toxicodendron). Several of the gums have been noticed under Acacia. Others of local importance are yielded by *Odina gummifera* Bl., of Java, *Sclerocarya* Sp. (*Dila*) and by the stem of the *Mango* (*Amba*) and that of *Schinus mollis* L. That from the stem of *Anacardium occidentale* L. is in commerce under the name of *Cashew-gum* and very similar gums are yielded by *A. humile* St. Hil. and *A. nanum* S. Hil., of Brazil. From the seeds of *Sclerocarya Birrea* Hochst. (*Spondias B.* A. Rich.), of Senegambia, a commercial fixed oil is extracted. The fruit of *Mangifera macrocarpa* Bl., of Java, and the bark of *Comocladia integrifolia* Jack., of eastern Asia, are used as hypnotics, and the barks of *Mangifera fœtida* Lour. and *M. cæsia* Jack., both of the East Indies, as fish poisons. The fruit of *Bouea oblongifolia* (the *Cangoura* of Salvador) is a convulsive, and the embryo of *Corynocarpus lævigata* Forst., of New Zealand, is poisonous. Though many of the juices are such powerful irritant poisons, others find valuable uses as vulneraries, especially those of *Astronium fraxinifolium* Schott, the *Gurubu preto* or *Gonzalo albez* of Brazil, and *A. graveolens* Jacq., of New Granada. Of *Duvaua dependens* DC. (*Schinus d.* Orteg.), the bark itself is similarly used. The wood, bark, and leaves of *Schinus mollis* L. are all aromatic and variously employed in native medicine, as are those of nearly a dozen other species of that genus, also those of *Lithræa Arocirinha* March (*Schinus molleoides* Vell.). The fruit of *Schinus mollis* L., the *Pepper tree* of western South America, is a well-known condiment, used as a substitute for black pepper, and also medicinally like cubeb. Its essential oil has been found to contain carvacrol

and phellandrene. The juice of *Holigarna longifolia* Roxb. is used to ease toothache. For the same purpose, and as vulneraries, are used the resinous bark and fruits of *Myracrodendron urundum* Fr. All., of Brazil.

Besides those specifically mentioned below, the following yield edible fruits: a half dozen species of *Spondias*, especially *S. purpurea* Mill. (*Spanish Prune, Mombin-plum, Hog-plum, Otaheiti apple, Ciruelo*), *S. lutea* L., both of tropical America, *S. dulcis* Forst., of the South Sea Islands, and *S. mangifera* W. (*Ngan-mo-leh, Yuh-kan-tsze, Ambra* or *Ambada, Pundi*, etc.), of India. The bark and wood of all these species are used as astringents, and the last-named yields a resin. The same is true of *S. venulosa* Mart., of Brazil and Paraguay, which also yields a gum very similar to that of the Caju. The fruit of *Dracontomelum mangiferum* Bl., of the East Indies, is used like citrons, and the leaves of this and other species of the genus find medicinal employment. From the seeds of *Duvaua dependens* (Ort.) D.C., the *Huingan* of western South America, is prepared a fermented drink which enjoys a great local medicinal repute. Other edible fruits are yielded by *Comocladia integrifolia* Jack., of tropical America, *Mauria multiflora* Mart., of the Amazon Valley, *Bouea Gardaria* Bl., of Java, and *B. Burmanica* Griss., of Burmah.

The following requires special mention:

ANACARDIUM, the *Cashew* or *Caju-nut* (*Caschunuss*, G.; *Acajou à pommes*, Fr.; *Anacardo*, Sp.), is the fruit of *Anăcardium occidentale* L., removed from its fleshy peduncle. This plant is a large shrub or small sprawling tree, native of tropical America, but largely cultivated and somewhat naturalized in many tropical countries. The root is said to be used as a purgative. After flowering, the peduncle becomes fleshy and enlarges to the size and form of a medium-sized pear. Until perfectly ripe, this is extremely astringent, and is medicinally so employed. After maturing, it is sweet, and consists almost entirely of a watery juice which is used for its thirst-quenching and refrigerant properties. In Brazil a wine is made from it, closely resembling Madeira and having a high repute for its use in so-called torpidity of the liver. Its alcohol is also distilled. The drug Anacardium, here considered, is the ripened 1-seeded ovary, borne upon and slightly imbedded in the tip of this fleshy portion. When mature, it is shaped like a large kidney bean, about 25 Mm. (1 In.) long, nearly as broad, and ½ to ⅓ as thick. It is of a grayish-brown to a dark-brown color, smoothish, with a rough scar at one end, and inodorous. It has a hard, brittle shell, and contains a white seed of its own form and having a mild oily taste. This kernel is roasted and eaten like chestnuts or peanuts. The fixed oil expressed from it is an article of commerce. In the middle layer of the shell exists an oily acrid liquid, capable of poisoning the skin like RHUS TOXICODENDRON, turning intensely black on exposure to the air and somewhat utilized as an indelible writing-fluid. The pericarp has been found to contain tannin, a little gallic acid, and resin. The brown oil is soluble in potassium hydroxide, with a red color, darkening on exposure, and its alcoholic solution yields a red precipitate with basic lead acetate (*Basiner*). Stædeler (1847, 1848) separated the vesicating principle, *cardol*, $C_{21}H_{30}O_2$, as a yellowish or reddish oil, evolving, when heated, a faint aromatic odor, and readily soluble in alcohol and ether. It is obtained from the ethereal extract, which is washed with water to remove tannin, dissolved in alcohol, and digested, and afterward boiled with hydrate of lead to remove *anacardic acid* and ammonia salt. The remaining color is removed by a little basic lead acetate. Cardol may be separated from mixtures by extraction with glacial acetic acid and subsequent agitation of the latter with benzol (*Basiner*). Anacardic acid, when pure, is white and crystalline, has an aromatic, afterward burning taste, but is not vesicating.

FIG. 21.

Anarcadium occidentale L.

The *Oriental cashew-nut*, known as *Anacardium orientale*, is the fruit of *Semecarpus Anacardium* L. or *Anacardium latifolium* Lam., a tall tree of India. The "nut" is about 25 Mm. (1 In.) long, nearly heart-shaped, flattish, obtuse, smooth, glossy, and nearly black. The pericarp and cotyledons have the same properties, and probably the same constituents, as the preceding; but Basiner (1881) ascertained that the brown oil of the mesocarp dissolved in potassa with a green color, and its alcoholic solution turns black with basic lead acetate.

The mango (from *Mangifera Indica* L.) is one of the most important fruits of the world, taking the place in the tropics which the peach occupies in temperate regions, and presenting about as many cultivated varieties. Its seed is used as an anthelmintic, the juice of its trunk as an antisyphilitic, and its bark and leaves as astringents. The fruits of *M. laurina* Bl. (the *Monkey mango*), *M. Taipon* Ham., and *M. Utana* Ham., are similarly eaten, but to a less extent.

ANDROPOGON.

(Fam. *Gramineæ*.)

This genus is treated in the most diverse ways by different authors. As regarded by Engler and Prantl, who are here followed, it contains nearly 200 species and represents a number of subgenera which are held as distinct genera by other authors. The species are mostly tropic, and are especially abundant in India and other parts of the old world. The subgenus *sorghum* will be considered under Saccharum. From *A. annulatus*, widely distributed in the old world, is obtained a manna containing 75 per cent of mannite (*Baker and*

Smith). The chief importance of the genus is owing to the presence of volatile oils in a large number of its species, these being coarse, tufted grasses, on which account many are extensively used in domestic and native practice as aromatics and stimulants. Some of the oils are distilled and are important articles of commerce (see Oils of Citronella, Lemon, Geranium, Vetivert, etc.).

Vetivert or *Vetiver* (*Cus-cus, Khas, Bala, Vala, Varelu, Baladvery, Panni, Usira, Virana*, etc.) is the rhizome and roots of *A. squarrosus* L. (*A. muricatus* Retz., *Anatherum m.* Retz., *Vetiveria odorato* Virey), of the East Indies, and cultivated in various parts of tropical America. It occurs as a dense, matted, reddish-brown, fibrous mass, having a somewhat aromatic odor and an aromatic, rather pungent taste. It has been considerably employed as an aromatic, carminative, and diaphoretic. In the same way are used the similar rhizomes and roots of *A. bicorne* L., *A. densiflorus* Steud., and *A. spatiflorus* Kunth., all of Brazil, and *A. laniger* Desf. (*Fœnum Camellorum*), of Persia. *Radix Ivarancusæ*, also an article of commerce, is the similar rhizome and roots of *A. Ivarancusa* Roxb., of India.

ANETHI FRUCTUS, *Br.*—Anethum.

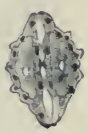
Dill, G.; *Aneth, Fenouil puant*, Fr.; *Eneldo*, Sp.

The fruit of *Anethum graveolens* L. (*Peucedanum g.* B. et H.—Fam. *Umbelliferæ*), a small yellow-flowered annual of southern Europe and adjacent Asia, and widely cultivated. The plant is sometimes used as a kitchen vegetable.

The fruit is oval, about 3 to 5 Mm. ($\frac{1}{8}$ to $\frac{1}{5}$ In.) long, dorsally compressed, of a brown color, and separates when ripe into 2 mericarps, which are flat upon the face and somewhat convex upon the back, the 3 dorsal ribs filiform and rather sharply keeled, while the 2 lateral ones are extended into a broad light-colored membranous margin; oil-tubes 6; odor and taste strong, resembling those of caraway.

Fig. 22. Fig. 23.

Indian anethum (×6).



German anethum: cross-section (×5).

The Indian variety, by some regarded as a distinct species (*A. Sowa* Roxb.), is here figured. The European variety is much broader in proportion to its length, and is also thinner and less rounded on the back, and usually darker colored than the Indian, which is more frequently stalked and with the mericarps united. The active constituent of dill is its 3 to 4 per cent. of volatile oil (see Oleum Anethi). It has the properties and uses of that oil, medicinally, and is very extensively used as a flavoring and condiment, especially by bakers and picklers.

Pharmaceutical Preparation.—Dill Water, Br. P.

Action and Uses.—Anethum is stimulant, aromatic, and carminative. It is rarely employed in America, but may be used in the treatment of flatulent colic, gastric indigestion, and hiccough. The fruit may be given in substance in the dose of from 15 grains to 1 drachm (1–4 Gm.). The usual dose of the volatile oil is from 2 to 5 minims (0.10–0.30 Cc.). An infusion, made with 1 ounce (30 Gm.) of the fruit and 1 pint (480 Cc.) of boiling water, may be administered in doses of from 1 to 2 fluidounces (30–60 Cc.).

ANGELICA.

Angélique, Fr.; *Angelica*, Sp., It.

Under this name are used various parts of a number of the highly aromatic species of the genus *Angelica* L. (Fam. *Umbelliferæ*), of which there are some 50, widely distributed through temperate and subtropical regions. The name is commonly, and officially in some pharmacopœias, construed as the roots of 2 species, as follows:

European Angelica (*Garden angelica, Arkangel, Holy ghost root, Angelicawurzel, Enelwurz*), the root of *A. Archangelica* L. (*A. officinalis* Moench, *Archangelica o.* Hoffm.). A stout perennial herb, about 2 M. (6 Ft.) high, native of northern Europe and extensively cultivated, especially in Germany, for the root, which is wholly produced from the cultivated variety, regarded by some botanists as a distinct species (*A. sativa* Fries).

Description.—European or garden angelica root (Fig. 29) consists of a short, thick rootstock, which is closely annulated above, and below abruptly divided into a large number of

nearly simple branches, which are about 6 Mm. (¼ In.) thick and 15 Cm. (6 In.) or more long, longitudinally wrinkled, of a dark-brown color externally, yellowish inside, with a spongy, radiated meditullium and numerous shining resin-cells in the thick bark. It has a strong aromatic odor and a sweetish, pungently aromatic and bitter taste, and breaks with a smooth, somewhat waxy fracture. The roots frequently come braided into fanciful forms.

Fig. 24.

German angelica (½ Nat.).

All forms of angelica root are greatly subject to destruction by larvæ and have to be carefully preserved.

Constituents.—Angelica contains a white waxy matter, crystallizing in wart-like masses from hot alcohol; *angelicin*, which is a somewhat acrid acid resin, soluble in alkalies and crystallizing in colorless needles from alcohol; volatile angelic acid ($C_5H_8O_2$), which crystallizes in colorless prisms, melts at 45° C. (113° F.), boils at 190° C. (314° F.), has a peculiar aromatic odor and a strongly acid taste, and when melted with potassium hydroxide yields propionic and acetic acids; an amorphous bitter principle; a little tannin, pectin, etc. (*Buchner*). The important constituent is about 0.5 per cent. of volatile oil, which has been thoroughly studied (see Oleum Angelicæ).

American Angelica Root, from *A. atropurpurea* L. (*Archangelica a.* Hoffm., *A. triquinata* Mx.), the *great, high*, or *purple angelica*, common in the northeastern United States, is similar, but is well distinguished by its lighter gray-brown color, its fewer branches, usually smaller, fewer resin-dots in the bark and less strong aroma, which, though similar to that of the European, is sufficiently distinct. Its composition, properties, and uses are very similar.

Fig. 25.

American angelica (rhizome, ½ Nat; root, ¾ Nat.).

Wild Angelica (the roots of *A. sylvestris* L. of Europe) is of a light gray-yellow, white within and more woody. *Smaller angelica, Southern angelica*, or *Hairy angelica*, the root of *A. villosa* (Walt.) B. S. P., of the southern United States, is similarly used. The root of *A. refracta* Fr. Sch., of Japan, is there known as *Moshiu-kuna* or *Yakara-kuna*. At least half a dozen other species are similarly used. The properties and uses are not confined to the roots, all other parts of the plants, especially the fruits, being used, and the oil being distilled from them. The fresh stems are frequently candied and used as a confection.

Pharmaceutical Preparation.—Fluidextract of Angelica, N. F.

Action and Uses.—Angelica is not employed extensively in medicine, but has been used as a stimulant and tonic, and when administered in warm infusion as a diaphoretic and emetic. The drug has been recommended as a stimulating expectorant in chronic inflammation of the upper air-passages. In the treatment of the milder types of intermittent fever angelica has met with favor, but it is probably of no more value than any of the ordinary simple bitters. It was formerly employed in the nervous forms of enteric fever, but its use in this connection has been abandoned.

Angelica may be given in substance in the dose of from 10 to 30 grains (0.60–2 Gm.) in powdered form. An infusion (made with 1 ounce (30 Gm.) of the root and 1 pint (480 Cc.) of water) may be given in doses of from 1 to 2 fluidrachms (4–8 Cc.).

ANILINA.—Aniline.

Amidobenzene, *Phenylamine*, E.; *Aniline*, Fr.; *Anilin*, G.

Formula, C_6H_7N or $C_6H_5NH_2$. Molecular weight, 92.39.

Origin.—Aniline was discovered by Unverdorben (1826) among the products of the dry distillation of indigo, and was found by Runge (1833) in the heavy oil of coal-tar. Zinin (1842) introduced the method of preparing it from nitrobenzene by the action of hydrogen sulphide in the presence of alcohol and ammonia, and A. W. Hofmann (1845) by nascent hydrogen from the action of dilute sulphuric acid upon zinc. The name *aniline* (from *anil*, the Portuguese name for indigo) was proposed by Fritzsche (1841). Aniline has been variously called by its discoverers in different substances, as *krystallin* by Unverdorben, *kyanol* by Runge, *benzidam* by Zinin, and the identity of these as aniline was finally established by Hofmann in 1845. It came into commercial use through the discovery of *mauve violet* by Perkins in 1856.

Preparation.—Aniline is prepared from nitrobenzene by the reducing action of nascent hydrogen, by digesting with a mixture of iron filings and acetic acid, as suggested by Béchamp, in which case the deoxidizing action of ferrous acetate, $Fe(C_2H_3O_2)_2$, first produced, materially assists the change. Nitrobenzene is thereby converted into aniline and water: $C_6H_5(NO_2) + 3H_2$ yields $C_6H_5NH_2 + 2H_2O$. The acetic acid has been replaced, by Brimmeyr, by hydrochloric acid. When, after several days, the reaction is completed, milk of lime is added and the aniline is distilled off, the receiver being changed toward the close of the distillation; the temperature then rises, and a red oil, *azobenzid*, $C_{12}H_{10}O_2$, passes over, which congeals to a crystalline mass. The separation of aniline from the heavy oil of coal-tar is effected by a complicated process depending upon its solubility in hydrochloric acid, the insolubility of this compound in ether, the liberation of the bases by an alkali, and their separation from each other by fractional distillation. Pure aniline is now prepared mostly from benzene as the starting-point.

Properties.—Aniline is a colorless, limpid, oily, strongly refractive, inflammable liquid, of a peculiar wine-like odor and burning aromatic taste. It has the specific gravity 1.0265 at 15° C. (59° F.), congeals at a low temperature, melts at —8° C. (17.6 F.), boils at 184.5° C. (364.1° F.), acquires in contact with air a yellow and brown color, is sparingly soluble in cold water (33 parts) and in all proportions of wood-spirit, alcohol, ether, aldehyde, acetone, and fixed and volatile oils. It dissolves phosphorus, camphor, several resins, and by the aid of heat much sulphur; coagulates albumin; precipitates the salts of iron, zinc, and aluminum; and unites with acids to form salts, which are mostly crystallizable, readily soluble in water, inodorous and colorless, but acquire a red color in contact with the air; alkalies decompose them, with the separation of aniline. Commercial pure aniline usually contains about 1 per cent. of toluidine; other grades contain more of this base, and are named mostly according to the colors to be made from the same. "Aniline for blue," next to pure aniline, is the purest commercial variety. "Aniline for red" and "aniline for safranin" are mixtures of aniline, orthotoluidine, and paratoluidine. *Toluidine* or *amidotoluene*, C_7H_9N or $C_6H_4CH_3NH_2$, exists in 3 modifications, of which 2 are present in the product of the above process. *Paratoluidine* forms colorless tabular crystals, melts at 45° C. (113° F.), and boils at 198° C. (288.4° F.). *Orthotoluidine* or *pseudotoluidine* is a colorless liquid of the same density as water at 15° C. (59° F.), boiling at 199.5° C. (390.2° F.), and not solidifying at —20° C. (—4° F.).

Tests.—Aniline should have the specific gravity and boiling-point above stated, and dissolve clear in 2 volumes of hydrochloric acid, the solution to remain clear on further dilution. Its aqueous solution on the addition of solution of chlorinated lime, or hypochlorite, develops a *violet* color (distinction from toluidine, which develops a reddish color). Acidulated with sulphuric acid the aqueous solution develops, after some time, a green to black color with potassium dichromate; or, if contained in a platinum receptacle and touched with the negative pole of a galvanic battery (Letheby), a transient play of colors from blue, through violet to pink, results.

Action and Uses.—The inhalation of fumes of aniline and the ingestion of large amounts of the drug itself produce alarming symptoms, which have been frequently followed by a fatal issue. When either inhaled or ingested in large amount, the drug produces weakness of the lower extremities with sometimes complete prostration, more or less cyanosis, headache, vertigo, lancinating pains, with nausea and vomiting. Reflex and

pupillary action are abolished, voluntary movement is held in abeyance, circulation is impaired, respiration becomes rapid and irregular, and bronchial irritation and cutaneous eruptions manifest themselves. Epileptiform convulsions and coma rapidly ensue, and if the patient survives hæmoglobinuria and jaundice become marked. There is a great reduction in the red blood-corpuscles, and the spectroscope gives the characteristic band of methæmoglobin. When locally applied, the drug sometimes causes cutaneous eruptions, eczematous or even gangrenous in character, which, however, may be due to contamination with arsenic. Aniline itself is rarely employed in medicine, but some of its derivatives have been quite largely used in antiseptic practice, and a few have been given internally in the treatment of disease. The drug itself has been recommended in the treatment of chorea, in daily doses of from 3 to 5 grains (0.20–0.30 Gm.), and while seemingly successful in a few cases, it has not given good results in others. Aniline camphorate is said to possess antispasmodic properties, and it too has been employed in chorea and other conditions attended with minor spasm, but it has never gained the confidence of physicians. The dose is stated to be from 5 to 10 grains (0.30–0.60 Gm.). Aniline sulphate has been given as a nervine and antispasmodic in doses of from ½ to 5 grains (0.025–0.30 Gm.), but is rarely if ever employed at the present time. Fuchsin was formerly considered as a possible remedy in the treatment of albuminuria and scarlatinous dropsy resulting from parenchymatous nephritis, but for these conditions it is now practically abandoned. Among the various derivatives of this drug which have been employed in antiseptic practice, methyl-violet stands preëminent. In the strength of 1 : 1000 it destroys the ordinary micro-organisms which produce pus, and in stronger solution will kill anthrax bacilli. Its use, however, is gradually decreasing because of the stain which it leaves, and the fact that the older antiseptics are equally efficacious. Closely allied to this remedy is *safranine* and "yellow pyoktanin," both of which may be used interchangeably with methyl-violet. They have been recommended in the treatment of conjunctivitis, blepharitis, corneal ulcer, and eczema of the eyelids. Pyoktanin is probably of more value in the treatment of diseases of the lacrymal apparatus, and for this purpose it is still largely employed. It has been used with asserted success in purulent otitis, tubercular laryngitis, and in tubercular sinuses and fistulæ. A solution (1 : 500 water) filtered through hot asbestos has been employed in doses of from ½ to 3 fluidrachms (2–12 Cc.) hypodermically for the purpose of retarding the growth and relieving the pain of malignant neoplasms. Should it produce sloughing, the area should be dressed antiseptically. Practically all of the aniline dyes possess antiseptic properties, but they should be used guardedly because of their poisonous properties. A number of them are employed for staining tissues and bacteria, the most common being fuchsine, methylene-blue, gentian-violet, and malachite-green.

Derivative Products.—BROMAMIDUM. *Bromamide, Tribromaniline hydrobromide, Bromaniline hydrobromide,* E.; *Bromwasserstoffsaures, Tribromanilin, Bromamid,* G. $C_6H_2Br_3NH_2.HBr$. Molecular weight, 407.83. Contains 77.8 per cent. of bromine.—Bromamide is prepared by reducing nitro-tribromo-benzene with tin and sulphuric acid. The tin is precipitated with hydrogen sulphide, and the tribromaniline combined with hydrobromic acid. It occurs as colorless, odorless, tasteless needles, insoluble in water, sparingly soluble in cold but soluble in 16 parts of boiling alcohol, and soluble in ether, chloroform, and oils; melts at 117° C. (242.6° F.), and is volatile at about 150° C. (302° F.) without decomposition.

PHENYLHYDRAZINE.—$C_6H_5N_2H_3$ or $C_6H_5.NH.NH_2$.—This compound is not used in medicine, but is of considerable interest as a reagent for the purpose of identifying aldehydes ketones, etc., with which it forms both crystallizable and non-crystallizable compounds, known as phenylhydrazones. It is a monacid base forming well-crystallized salts, and possesses strong reducing properties. Phenylhydrazine may be obtained by dissolving 10 Gm. of aniline in 200 Gm. of strong hydrochloric acid, cooling the solution, and adding 7½ Gm. of sodium nitrite dissolved in about 50 Cc. of water. To this liquid, which contains diazobenzene chloride, is then added 45 Gm. of stannous chloride dissolved in an equal weight of hydrochloric acid The mixture soon sets into a white crystalline pulp of phenylhydrazine hydrochloride, from which the free base may be obtained by adding an excess of alkali and extracting with ether It occurs in monoclinic plates, which melt at 17.5° C. (63.5° F.), sparingly soluble in cold water, more soluble in hot water, and very readily in alcohol and in ether. Phenylhydrazine has been of great value in the study of the sugar group on account of its characteristic behavior toward these compounds. With glucose it forms a well-defined yellow crystalline compound known as glucosazone, $C_6H_{10}O_4(N_2H.C_6H_5)_2$, which melts between 204° and 205° C. (399.2° and 401° F.), and hence has been recommended as a delicate test for sugar in urine. Phenylhydrazine is also used in the manufacture of antipyrine.

By action of acetic anhydride, phenylhydrazine is converted into acetylphenylhydrazine, $C_6H_5.NH.NH(C_2H_3O)$, also known as *hydracetin* or *pyrodin*, which forms colorless hexagonal prisms, melting at 128.5° C. (263.3° F.), and difficultly soluble in cold water and ether, but readily soluble in hot water and in alcohol.

DIPHENYLAMINE.—$NH(C_6H_5)_2$.—A weak base, formed by heating aniline hydrochloride with aniline to 240° C. (464° F.). It occurs in the form of grayish-white or colorless monoclinic crystals, melting at 54° C. (129.2° F.), slightly soluble in water, and having a pleasant faint odor. It is a very delicate reagent for nitric acid and for chlorine, and is used both in the dry state and in solution. Diphenylamine test-solution is made by dissolving 0.1 Gm. of diphenylamine in 50 Cc. of diluted sulphuric acid. To test a solution for the presence of nitric acid, a small portion of it is mixed with 1 or 2 drops of diphenylamine test-solution, and then concentrated sulphuric acid, free from compounds of nitrogen, is poured in so as to form a layer beneath the solution, when the presence of nitric acid is shown by a deep-blue color at the zone of contact.

Under the name *sulphaminol*, thiooxydiphenylamine has been introduced into medicine as an antiseptic. It is a yellow, odorless, and tasteless powder.

SALTS OF ANILINE.

Anilinæ Camphoras; *Anilinum camphoricum; Aniline camphorate; Kamphersaures Anilin*, G. $(C_6H_5NH_2)_2C_{10}H_{16}O_4$. Molecular weight, 383.40.—Crystals soluble in water (30 parts), in glycerin (10 parts), and readily in alcohol or ether.

Anilinæ Hydrochloridum; *Anilinum hydrochloricum; Aniline hydrochloride; Aniline salt; Salzsaures Anilin*, G. $C_6H_5NH_2.HCl$. Molecular weight, 128.57.—Prepared by mixing 100 parts of pure aniline with 160 parts of pure hydrochloric acid of 1.123 specific gravity, and crystallizing. The crystals are colorless needles, easily soluble in water and alcohol. Melting-point 192° C. (377.6° F.). Used principally as a basis for various aniline dyes.

Anilinæ Sulphas; *Anilinum sulfuricum; Aniline sulphate; Schwefelsaures Anilin*, G. $(C_6H_5NH_2)_2.H_2SO_4$. Molecular weight, 282.13.—Prepared by mixing an alcoholic (600 parts) solution of pure aniline (100 parts) with a fresh and cold solution of concentrated sulphuric acid (55 parts) in alcohol (150 parts). After allowing the mixture to stand, 400 parts of ether are added, and the resulting crystals separated by filtering the liquid through asbestos. The crystals are colorless needles, easily soluble in water or diluted alcohol, less readily soluble in alcohol, and quite insoluble in ether.

ANILINE DYES.

The manufacture of aniline colors has grown into a most important chemical industry. Nearly all the aniline dyes used in the United States are imported from Europe; the importations having increased from 210,500 pounds in 1877 to 1,103,864 pounds in 1882, and to 3,072,915 pounds in 1896. The value of aniline colors imported during the 11 months ending May 31, 1902, was $4,596,727. The known varieties of the dyes number in the thousands.

Aniline colors are much used in the preparation of inks: 1 to 2 parts of the desired color with an equal weight of sugar or gum arabic are dissolved in 60 to 150 parts of water; and for copying-inks the water is reduced to one-half the amount.

A few of the more commonly used aniline dyes are:

Aniline Black, $(C_6H_5N)_n.2HCl$, is the hydrochloride of a base termed nigraniline, and is produced by the oxidation of aniline in acid solution with dichromate, chlorates with salts of a metal (copper and particularly vanadium), or electrolytic oxygen. It may be obtained by heating to 60° C. (140° F.) a solution of 4 parts of aniline hydrochloride, 4 parts of cupric sulphate, 2 parts of potassium chlorate, 1.6 parts of ammonium chloride, dissolved in 50 parts of water. In dyeing, owing to its insolubility, it is usually formed direct on the fibre. It is a black compound turned greenish by acids, but when sufficiently oxidized with dichromate the black is permanent and unaffected by acids or alkalies. It is insoluble in water, alcohol, acids, or alkalies. Strong oxidizing agents convert it to *quinone*, and heated with aniline acetate *induline* is formed.

Nigrosine, a sulphonated induline, occurs as a black powder, soluble in water with a bluish-violet, and in alcohol with a blue color.

Aniline Blue; *Rosaniline blue* and *Spirit blue* are salts of two series of triphenyl derivatives of the colorless bases *rosaniline*, $C_{20}H_{16}(C_6H_5)_3N_3$, and *pararosaniline*, $C_{19}H_{14}(C_6H_5)_3N_3$, yielding respectively the dyes *rosaniline blue, spirit blue, Paris blue*, and *para-rosaniline blue, diphenylamine blue, azuline, azurine*. These dyes are marked by their excellent dyeing qualities. They are sparingly soluble in water, but soluble in alcohol. By sulphonating water-soluble dyes are produced, the respective rosaniline derivatives being commercially represented by the sodium monosulphonate salt, as Nicholson's blue, alkali blue, soluble blue, and the para-rosaniline by *alkali blue* D. The depth of the blue dyeing properties is closely proportional to the number of phenyl radicles (C_6H_5) substituted for hydrogen in the base. By treatment with iodide of methyl or ethyl, and similar compounds, a large variety of blue, violet, and green (iodine-green, methyl-green, etc.) dyes are obtained.

Aniline Red, Magenta, Fuchsine, etc., is formed by heating to about 180° C. (356° F.) a mixture of aniline and toluidine with mercuric nitrate, arsenic acid, or nitrobenzene. It is a salt of *rosaniline*, $C_{20}H_{19}N_3$. Magenta was formerly the acetate, *roseine* (French) the hydro-

chloride, and *rubein* and *azaleine* the nitrate of the same colorless base rosaniline. The hydrochloride, $C_{20}H_{19}N_3.HCl$, which as commercial magenta and fuchsine, has superseded the others, occurs as bright-greenish iridescent crystals, sparingly soluble in water to a crimson solution, soluble in amyl alcohol, in 10 parts of alcohol, insoluble in essential oils and ether, and exhibits characteristic absorption spectra between the Fraunhöfer lines D and E. Its solutions readily dye silk or wool without a mordant. Alkalies decompose and decolorize its solutions by liberating the free base.

Aniline Yellow, $C_6H_5N_2C_6H_4NH_2.HCl$, *Spirit yellow*, is used principally as the basis for manufacturing more permanent aniline colors. It occurs as bright bluish-violet needle-shaped crystals. Chrysoidine, $C_6H_5.N_2.C_6H_3(NH_2)_2.HCl$, the hydrochloride of diamido-azobenzene, occurs as a reddish-brown powder or violet-colored crystals. Its aqueous solutions are brown to orange colored, and are turned red by mineral acids. Much used in conjunction with safranine to produce scarlets on cotton.

Methyl-blue.—This compound is the sodium salt of triphenylpararosaniline-trisulphonic acid, $C_{19}H_{11}(C_6H_5)_3N_3(SO_3H)_3$, which latter is made by treating pararosaniline with aniline and the resulting product with sulphuric acid. It should not be confounded with methylene-blue, which is used medicinally, and from which it can be distinguished by adding sodium hydroxide to a solution, which changes the color of methyl-blue to reddish-brown and that of methylene-blue to violet.

Pyoktanin.—Two varieties, yellow and blue pyoktanin, have been brought to notice, the latter intended for general surgery, the former more especially for ophthalmic practice. *Yellow pyoktanin*, also known as *apyonin* and *benzophenoneid*, is the hydrochloride of imido-tetramethyldi-p-amidodiphenylmethane, $C_{17}H_{23}N_3OHCl$, and is obtained by heating tetramethyldiamidobenzophenone with ammonium chloride and zinc chloride. It belongs to the group of aniline dyes known as auramines.

Blue pyoktanin, also called methyl-violet, is of variable composition, and consists chiefly of the hydrochlorides of penta- and hexamethylpararosaniline. It is a blue crystalline powder which dissolves in water and in alcohol, forming intensely blue-violet colored solutions.

Safranine, $C_{21}H_{20}N_4$, is a red basic compound obtained from aniline containing toluidine by treatment with nitrous and arsenic acids, or commercially by conversion into amido-azo compounds and subsequent oxidation. As a monacid salt *safranine, aniline pink*, is a reddish-brown powder, soluble in water and alcohol, and readily dyes animal fibres in alkaline solution.

ANISUM, *U. S.*—Anise.

Anisi fructus, Br.; *Anise fruit* (incorrectly "*Aniseseed*"), *Sweet cumin, Aneys, Anny, Annyle*, E.; *Anis* (incorrectly "*Anissamen*"), G.; *Anis vert*, Fr.; *Harva doce, Anicetum*, Port.; *Anace*, It.; *Ch'uen Kiang, Hwai Hiang*, Chin.

The dried ripe fruit of *Pimpinella Anisum* L. (*Anisum vulgare* Moench—Fam. *Umbelliferæ*).

Description.—Consisting of 2 carpels, mostly united and stalked, about 4 to 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ In.) long, ovate, tapering upward toward the thick stylopode, grayish or greenish-gray, each with 5 light-colored nearly entire ribs, the intervening spaces bristly-hairy; carpels not grooved on the face; oil-tubes 12 to 20; odor characteristic; taste sweet and aromatic.

Conium fruit is frequently admixed, occasionally in poisonous quantity. Its presence in the entire or powdered state, even in so small amount as 1 per cent., can be readily detected by the mousey odor developed on soaking it for an hour in water, especially if a little potassium hydroxide be added. Fruits from which the oil has been partially distilled may be distinguished by their shrivelled appearance.

FIG. 26. FIG. 27.

Anise: dorsal and lateral view (× 6), transverse section (× 8).

The powder is of a green-brown color, and shows hairs and crystals. The presence in it of star-anise may be distinguished by the peculiar sclerotic cells figured under Illicium. Much earthy matter is frequently present, and can be estimated on separation by stirring the anise in strong brine, when the latter will float, the former sink.

The largest and handsomest anise for pharmaceutical purposes is that grown in the Mediterranean region, but a large portion of distillers' anise comes from Russia. "Australian Anise," so-called, is the fruit of *Seseli Harveyanum* F. v. M., but it rarely if ever gets into commerce.

With 3 or 4 per cent. of fixed oil, some gum, sugar, resin, malates, and inorganic substances, the active constituent is about 3 per cent. of volatile oil (see OLEUM ANISI).

Action and Uses.—Anise is an aromatic stimulant and carminative. It has been used as a condiment, and is said to assist in the digestion of food. The infusion (anise, 50 Gm.; boiling water, 1000 Cc.) has been recommended in infantile diarrhœa of a subacute or chronic type. Like other aromatics, it may be employed in the relief of flatulence and intestinal colic, and when combined with purgative drugs prevents to a certain extent their tendency to gripe. The drug has been recommended as a stimulating expectorant in chronic inflammations of the respiratory tract. It probably does not increase the secretion of milk in nursing women, but sometimes imparts to the milk a disagreeable taste. The drug when powdered is given in substance in the dose of from 10 to 20 grains (0.60–1.30 Gm.).

The fruits of *P. Peregrina* L. and *P. aromatica* M. Bieb., both of Europe, are used as anise.

Allied Drugs.—The roots of several species of *Pimpinella*, especially *P. Saxifraga* L. and *P. magna* L., *Radix Pimpinellæ* (P. G.), *Pimpernel, Burnet Saxifrage, Bennet, Bidernell, Grand Bocage* (Fr.), of Europe, and *P. Panatjan* L., the *Panatjan* of Java, have a similar composition and use with those of the fruit.

ANONACEÆ.—The Custard Apple Family.

About 50 genera and some 400 species, almost all tropical shrubs and trees, inhabiting both continents. The chief economic properties, in their order of importance, are edible fruits, aromatics, bitters, and antiperiodics.

The *Cherimolia* or *Chirimoya*, from *Anona Cherimolia* Mill. (*A. tripetala* Ait.), of Peru, is one of the two or three most delicious of known fruits. The fruit of the same name (also called *Gandhagatra, Ata Lundu, Sitapunda*, etc., in India, and *Fan-lih-chi* in China, from *A. squamosa* L., cultivated in all tropical countries, is only a little less delicious. The *Soursop*, from *A. muricata* L., of tropical America, is also a very important fruit. A half-dozen or more other species of *Anona* yield edible fruits, as do *Rollinia Siberi* DC., of tropical America, *Polyalthia cerasoides* Benth., of India, *Unona Musaria* Dun., of Malabar, a number of species of *Uvaria*, and *Asimina triloba* Dun., of the central and southern United States, our *Paw-paw* (not *Papaw*).

Aromatic principles may exist in any of the plant-parts. The precious volatile oil *ylang-ylang* is distilled from the flowers of *Artabotrys odoratissima* R. Br. (*non L.*) and that known as *Minjah henangam* from *A. intermedia* Hook., of Java. The leaves of the last-named are used as an insecticide, as are the seeds of *Anona squamosa*. The aromatic fruits of several species of *Xylopia* are used as condiments, especially those of *X. sericea* St. Hil., the *Embira* or *Pinduiba* of Brazil, *X. aromatica* Aubl. (*Unona a.* Dun.), the *Meleguetta pepper* of Guinea, *X. Brasiliensis* Mart., used like cubeb, and *X. Æthiopica* A. Rich. (*Unona piperita* Afzel). The seed of *Unona ligularia* Dun. is used in perfumery, the leaves and seeds of *U. Narum* A. DC., of India, as carminatives and anthelmintics. Many other of the barks and seeds are in domestic use as aromatics.

Bitters, frequently used as antiperiodics, are yielded by the seeds of *Xylopia salicifolia* Kunth., and the bark and seed of *X. glabra* L., and the bark and leaves of *Guatteria sempervirens* Dun., the seed of the ylang-ylang plant and the fruit of *X. longifolia* A. DC. (*Fruta del burro*), of tropical America. The bark of *Cœlocline polycarpa* A. DC. (*Unona p.* DC.) is used similarly in Africa, as well as for dyeing, under the name of *Berberin tree* or *Yellow dye-tree* of Soudan. It contains berberine.

Tannin is rather abundant in various parts of many species, especially in the unripe *Anona* and other fruits.

Miscellaneous mention may be made of the anthelmintic uses of the leaves of *A. reticulata, A. muricata*, and *A. palustris* L.; of fish poisons yielded by the leaves of the last-named, by the root of *A. muricata* and by the fruit of *A. spinescens* Mart., of Brazil; of the drastic properties of the bark of *A. squamosa;* the emetico-cathartic properties of the roasted seeds of the *Cherimolia;* the emetic properties of the alkaloidal seed of *Asimina triloba*, the abortifacient properties of the root of *Goniothalmus macrophyllus* Hook., the *Aku-sinderah* of Java; of the properties, antidotal to curare, of *Guatteria laurifolia* Dun., *G. Ouregu* Dun., and *G. venificum* Mart., and of an arrow poison said to be made from the leaves of *Unona lucidula* Oliv. A tragacanth-like gum is obtained in India from *Saccopetalum tomentosum* Hook. f. et. Th. and a yellow dye-stuff from the leaves of *Porcelia nitidifolia* R. et P., of Peru. The seed of *Monodora Myristica* is said to be exported from Camaroons, to be sold as nutmeg.

ANTHEMIS, *U. S.*—Chamomile.

English, Garden, Low, Roman, or White chamomile or camomile, Camomile, Camil, Whig-plant, Camooyne, E.; *Flores Chamomillæ Romanæ.—Anthemidis Flores*, Br.; *Römische Kamille*, G.; *Camomille Romaine*, Fr.; *Camomilla dos Franceses, Macella Dourada*, Port.; *Manzanilla Romana*, Sp.; *Camomilla Ingleses*, It.

The dried flower-heads of *Anthemis nobilis* L. (*Chamomilla nobilis* Godr.—Fam. *Compositæ*), collected from cultivated plants.

The Br. P. definition requires that the flowers should be expanded before being collected. Specification of cultivated plants as the source, is in order to insure the "double

Fig. 28.

Anthemis nobilis L.: *a*, section through single flower-head (Nat.); *b* and *c*, ray- and disk-floret (mag. 4 diam.).

Fig. 29.

Anthemis cotula L.: *d*, leaf (reduced); *e*, flower-head (Nat.).

flowers"—that is, those in which most or all of the tubular or disk flowers have been substituted by ligulate or ray flowers, a result which follows upon high cultivation. Such flowers are more highly and more finely aromatic, and their flavor is less rankly and disagreeably bitter.

Origin.—The chamomile plant is a low, somewhat hairy perennial, native, and is very extensively cultivated in Europe and to a small extent in other temperate regions. The stems are slender and semi-prostrate, the leaves twice or thrice pinnately divided, their segments linear and acute.

Description.—Roughly and irregularly globose and scaly, 12.7 to 25 Mm. (½ to 1 In.) broad, white or cream-colored, yellow to brown when long kept; involucre green, saucer-shaped to nearly hemispherical, 6 to 9 Mm. (¼ to ⅜ In.) broad, the scales in several series, closely appressed, with scarious margins, the outer somewhat shorter; ray-flowers crowded in many series, recurved and often concealing the involucre, white, stiff, and somewhat papery, oblong, blunt, slightly 3-toothed or entire, 3-nerved, pistillate, fertile or neutral; disk-flowers few, yellow, tubular, 5-toothed, the upper half abruptly twice as broad as the lower, perfect, without pappus; receptacle conical, solid, densely chaffy, the chaff scarious, shining, obovate, blunt with erose margins; strongly aromatic and bitter.

Substitutes and Adulterants.—All are readily distinguished by their single circle of ray-flowers, except *Chrysanthemum Parthenium* (L.) Pers. (*Matricaria P.* L., *Pyrethrum P.* Smith), the *Feverfew, Featherfew, Fetter-foe, Febrifuge plant, Bertram, Whitewort, Mutterkraut* (G.), *Matricaire* (Fr. Cod.), and *Achillea Ptarmica* L., the *White* or *Sneezewort tansy, Goose-tongue, Bertramgarbe* (G.), *Herbe à Eternuér* (Fr.), which, though double, are much smaller, especially the latter. *Anthemis Cotula* L. (*Maruta C.* DC.), the *May weed, Dogs' camomile* or *Stinking camomile, Dog daisy, Horse daisy,* or *Poison daisy, Balders, Dog finkel, Jay weed,* and known by many other common names, very abundant as a roadside weed throughout the United States and nearly all other temperate zone countries, has like properties and is similarly used, as is *A. arvensis* L., the European *corn camomile,* rather commonly naturalized in the United States (see also Matricaria).

Constituents.—About 1 per cent. of volatile oil (see Oleum Anthemidis), 5.25 per cent. of resin, 1.50 per cent. of nearly white, bitter, crystalline wax, a bitter crystalline substance of glucosidal nature, a small quantity of an organic acid, possibly anthemic acid, a red-brown volatile liquid alkaloid (Dohme) with a characteristic odor and taste, a trace of tannin, fat, glucose, and 6 per cent. of ash are contained.

Pharmaceutical Preparation.—Extract of Anthemis, Br. P.

Action and Uses.—Anthemis, because of its volatile oil, possesses stimulant and antispasmodic properties. On account of its bitter principle it acts as a simple tonic. When administered in very large amount in warm infusion the drug produces emesis. Full doses may occasion purging, pain, and vertigo.

Chamomile has been employed as a carminative in flatulent colic and in the summer diarrhœas of children, and has met with favor when given in tepid infusion in the treatment of periodical sick headaches and the milder forms of intermittent fever, and as an emmenagogue. As a simple bitter, the cold infusion has been recommended in anorexia during convalescence from acute febrile conditions and in various other debilitated conditions attended with loss of appetite.

Hot fomentations, made with the flowers and water or vinegar, may be employed with advantage as stimulants to old and sluggish ulcers and for the relief of pain occasioned by deep-seated inflammatory conditions, as, for example, earache and rheumatism.

Anthemis may be given in substance in the dose of from ½ to 1 drachm (2–4 Cc.).

The Extractum Anthemidis, Br. P., is given in the dose of 3 grains (0.20 Gm.); the Tinctura Anthemidis, in the dose of from 3 to 10 minims (2–0.60 Cc.). The infusion is made with chamomile flowers (30 Gm.) in boiling water (1000 Cc.), and given in doses of from 1 to 2 fluidounces (30–60 Cc.).

ANTIARIS, *Fr., G.*—Upas; Antiar.

A gum-resinous exudation from *Antiaris toxicaria*, Leschenault (Fam. *Moraceæ*), a very large milky-juiced tree of the East India islands.

The exudation is white or nearly so upon exuding from the wounded bark, but quickly turns yellowish and finally reddish-brown. Its consistency is waxy, the taste very bitter and somewhat acrid. It is partly soluble in alcohol and ether.

Constituents.—It contains (Kiliani) *antiarol* ($C_9H_{12}O_4$), neutral, soluble in alcohol, sparingly in cold water, crystallizing in long needles and quadratic or rhombic plates; *antiarin* ($C_{27}H_{42}O_{10}$, $4H_2O$), a glucoside crystallizing in long silky needles and yielding *antiarigenin* ($C_{22}H_{30}O_5$); a third crystalline body with formula $C_{27}H_{36}O$. Betlink found also two other active constituents, *oepain* and *toxicarine*. Gum, sugar, wax, and resin also exist.

Action and Uses.—Antiaris is one of the East Indian arrow poisons, and there appears to be no record of its employment in medicine. When injected into the body, it causes paralysis by depressing the motor nerve-trunks. Apparently it has little effect upon the central nervous system. The drug acts as a paralyzing depressant poison upon the heart, vasomotor centers, and voluntary muscles. When administered in large amounts, muscular relaxation, involuntary evacuations, great prostration, a feeble, irregular pulse, and finally death by paralysis of the cardiac muscle result.

ANTIMONII ET POTASSII TARTRAS, *U. S.*—Antimony and Potassium Tartrate.

Antimonium tartaratum, Br.; *Tartarus stibiatus*, P. G.—*Tartarated antimony, Tartar emetic, Antimonyl potassium tartrate, Potassio-tartrate of antimony*, E.; *Tartrate de potasse et d'antimoine, Emétique, Tartre stibié*, Fr.; *Brechweinstein*, G.; *Tartrato di antimonio e di potassio*, F. It.; *Tartrato de potassa y antimonio*, Sp.

Formula, $2K(SbO)C_4H_4O_6 + H_2O$. Molecular weight, 659.80.

It should contain not less than 99.5 per cent. of pure antimony and potassium tartrate, and should be kept in well-stoppered bottles.—U. S.

Origin.—A process for the preparation of tartar emetic from cream of tartar and crocus of antimony was first published in 1631 by Adrian van Mynsicht. Glauber (1648) used flowers of antimony or antimonial glass. At present the salt is generally prepared from pure oxide of antimony.

Preparation.—Tartar emetic, like many other chemicals, is best made on the large scale, and different methods, as to details, are employed by different manufacturers. Essentially, however, all processes consist in the action of acid potassium tartrate on antimonous oxide, whereby the free acid hydrogen atom of the tartrate is replaced by the antimonyl group (SbO); thus, $Sb_2O_3 + 2KHC_4H_4O_6 = 2K(SbO)C_4H_4O_6 + H_2O$. On the large scale impure oxide of antimony is used, such as antimony ash, and the product purified by crystallization, as the gain in cheaper raw materials offsets the loss in the waste of the impure mother-liquors. For the pharmacist, it is more advantageous to use pure materials, since with proper and careful manipulation the entire solution may be made to crystallize. The present U. S. Pharmacopœia gives no process and the British gives only outlines of one. The method formerly recognized by the U. S. P.

was practically as follows: 4 parts of oxide of antimony and 5 parts of acid potassium tartrate, both in fine powder, were added to 36 parts of water boiled for some time (1 hour). The liquid was filtered hot, concentrated, and set aside to cool and crystallize. The crystals should be dried on filter-paper in the air.

The former British method was this: 5 ounces of oxide of antimony were mixed with 6 ounces of finely powdered acid potassium tartrate and sufficient water to form a paste, and set aside for 24 hours. Then 2 pints of distilled water were added and boiled for a quarter of an hour, with frequent stirring, the solution was filtered and set aside to crystallize. The mother-liquor was concentrated, whereby a second crop of crystals may be obtained.

In the U. S. process, the long boiling is apt to produce a change whereby the liquid becomes colored and an uncrystallizable compound is produced. In the British process long boiling is avoided, the combination taking place mainly in the cold, while the subsequent boiling is intended merely to bring into solution the tartar emetic already formed. It is of importance that the antimonous oxide should be free from oxychloride, otherwise the mother-liquor will become acid, and more or less of the salt will be lost by refusing to crystallize. The acid potassium tartrate should be free from calcium tartrate, which would contaminate the crystals of tartar emetic, necessitating their recrystallization, and thus occasioning loss. The oxide of antimony should be in slight excess, as otherwise if the acid tartrate is in excess the latter will crystallize out with the tartar emetic.

Berzelius and later Henry used the oxychloride of antimony (powder of Algaroth) to prepare tartar emetic.

Properties.—Antimony and potassium tartrate forms colorless transparent crystals, which have the shape of a rhombic octahedron, become white and opaque on exposure to the air, and have a sweetish, afterward disagreeable, strongly metallic taste. In commerce it is usually seen in the form of a white finely granular powder. Heated to 110° C. (230° F.), the salt loses its water of crystallization, 2.71 per cent.; at 200° C. (392° F.) it parts with more water, and is converted into metatartrate; at a higher heat it decomposes, becomes brown and black, giving off empyreumatic products having the odor of burning sugar, and finally leaves a black or gray residue having an alkaline reaction. Tartar emetic is soluble in 15.5 parts of water at 25° C. (77° F.) and 3 parts of boiling water (U. S.); in 15 parts of water at 15.5° C. (60° F.) (Br.).

The aqueous solution is precipitated on the addition of alcohol in the form of a crystalline powder; in this manner a pure powder of tartar emetic is readily and most advantageously obtained for pharmaceutical purposes. The solution yields with hydrochloric and other mineral acids a white precipitate of an oxy-salt of antimony, which is soluble in hydrochloric acid, and does not occur if tartaric acid has been previously added to the solution. The aqueous solution, even if largely diluted, at once becomes turbid on the addition of a little potassium carbonate. Hydrogen sulphide causes an orange-red precipitate, which, when obtained from 2 Gm. of the salt after washing and drying at 100° C. (212° F.), weighs 1.012 Gm. A solution of tartar emetic which is not too dilute produces a flocculent precipitate on the addition of infusion of galls; an excess of the latter redissolves the precipitate. The salts of most metals and earths, being precipitated by normal tartrates, are incompatible with tartar emetic; also the alkalies, tannin, and tinctures containing tannin.

Tests.—Chlorides and sulphates, if present, are detected in the solution, previously acidulated with acetic acid, by silver nitrate and barium chloride, calcium by ammonium oxalate, and copper, iron, and other metals by potassium ferrocyanide. A 1 per cent. solution of the salt should not be clouded by the addition of a few drops of the reagents named.—U. S. Arsenic may be detected by carefully heating 20 or 30 grains of the salt until a black residue remains; on gradually increasing the temperature to redness a garlic-like odor will be evolved. More delicate tests are the following: If 2 Gm. of the salt be dissolved, with the aid of heat, in hydrochloric acid, and to this solution 1 Cc. of test-solution of stannous chloride be added, no turbidity or coloration should ensue within 1 hour (limit of arsenic).—U. S. If 1 Gm. of tartar emetic, in powder, be shaken with 3 Cc. of solution of stannous chloride, no coloration should ensue within 1 hour.—P. G. The impurity which is likely to be met with in consequence of faulty preparation is cream of tartar, the presence of which cannot be detected by its behavior to test-paper, since the solution of tartar emetic has an acid reaction; but a permanent

precipitate will not appear with potassium carbonate until after this impurity has been neutralized. By dissolving 24 grains of the salt in a fluidounce of warm water and cooling the solution to 10° C. (50° F.) it should remain clear. A crystalline deposit will occur if more than 8 per cent. of cream of tartar is present. The U. S. P. demands that if sodium carbonate (bicarbonate, Br.) solution be added to crushed crystals of tartar emetic, no effervescence should take place, to show absence of this impurity. A more delicate test, which, however, does not indicate the nature of the impurity, consists in preparing antimony sulphide from a given weight of the salt, as stated above. If to a 5 per cent. solution of the salt just sufficient sodium hydroxide test-solution be added to redissolve the precipitate formed, and if to this solution an equal volume of a fresh hydrogen sulphide test-solution be added, no coloration should be noticeable after standing in a warm place for half an hour when viewed by reflected light against a white surface (absence of heavy metals). If 1 Gm. of the salt be dissolved in water to 100 Cc., then 33 (32.99) Cc. of this solution should, after the addition of 20 Cc. of a cold saturated solution of sodium bicarbonate and a little test-solution of starch, require not less than 19.9 Cc. of decinormal iodine solution to produce a permanent blue color (corresponding to 99.5 per cent. of the pure salt).—U. S. Each Gm. should require between 60.2 and 60.7 Cc. of iodine solution, corresponding to 99.2–100 per cent., Br.; 0.2 Gm. should require 12 Cc. of iodine solution, corresponding to 99.66 per cent., P. G. The following equation will explain the reaction taking place in the test: $2(KSbOC_4H_4O_6).H_2O + 8NaHCO_3 + I_4 = 2NaSbO_3$ (meta-antimonate) $+ 4NaI + 2KNaC_4H_4O_6 + 8CO_2 + 6H_2O$. Now, since 503.6 ($125.9 \times 4$) parts of iodine are necessary to oxidize completely the antimony contained in 659.80 parts of crystallized tartar emetic, it follows that 19.9 Cc. of decinormal iodine solution, representing 0.250541 Gm. of iodine, are required for 0.32835 (0.33 at 99.5 per cent.) Gm. of the salt, for 659.8 : 503.6 :: 0.32835 : 0.2506. Titration should begin immediately after the addition of the sodium bicarbonate solution.

Action and Uses.—Tartar emetic was at one time largely employed as an expectorant, diaphoretic, emetic, sedative, antiphlogistic, and counterirritant, but at present its use has become greatly limited. When locally applied to mucous membranes, it causes a sensation of burning, which is followed by vesication if the contact be sufficiently prolonged. Upon the skin it acts as a rubefacient and irritant, and its continuous application causes a pustular eruption followed by deep sloughing. The surrounding tissue becomes devitalized and the resulting ulcer heals very slowly. Antimony depresses the sensory side of the spinal cord, and in poisonous dose paralyzes both the sensory and the motor centers in the cord. It lowers both the pulse-rate and pulse-force. The heart muscle is directly depressed by small amounts, and large doses probably depress the peripheral vagus nerves. Blood-pressure is lowered first, because of the depressed heart's action, and second, because of depression of the vasomotor system. The depression of the vasomotor system may be in part centric, but it is certainly due also to depression peripherally. The convulsions sometimes seen are due to circulatory depression with anæmia of the base of the brain. Moderate amounts do not affect the respiratory function, but lethal doses depress the respiratory center and the vagus nerves supplying the lungs, produce pulmonary congestion resulting from cardiac failure, and cause a large outpouring of mucus into the bronchial tubes. Tartar emetic, especially when assisted by copious draughts of water and diaphoretics, stimulates the secretion of the skin to a very marked degree. It is an irritant to the stomach and intestines, and in toxic dose produces violent gastro-enteritis. It causes vomiting by stimulating the vomiting center in the medulla and by irritating the gastric mucosa. The purging following overdose of this drug is an effort made by the intestines to eliminate the poison, and is due also to the intense intestinal inflammation. Antimony is very slowly absorbed from the stomach and intestines, and is slowly eliminated by all the secretions and by the bowels.

Tartar emetic may be employed as a circulatory depressant in all sthenic inflammatory conditions, as, for example, in the very early stages of bronchitis and pneumonia, for aborting beginning colds and other localized inflammations. It should never be employed in adynamic conditions where the heart's action is feeble, and little or no excess of temperature is present. As an expectorant, it is useful especially when combined with other drugs in the beginning stages of acute bronchitis. It is also useful in the above-named conditions for its diaphoretic properties. Minute doses of this drug may be used in the treatment of vomiting resulting from depression, but never when the

vomiting is occasioned by gastric irritation. Doses of $\frac{1}{60}$ grain (0.001 Gm.) may be used successfully in treating the acute gastric catarrh of children when associated with fever. As an emetic, it causes great prostration and muscular relaxation, and before the introduction of anæsthetics advantage of this fact was taken in order to reduce dislocations and strangulated hernias and to dilate the os uteri. It is too slow and prolonged in its action to render much service as an emetic in the treatment either of disease or of poisoning by other remedies. Locally the plaster or ointment (see Emplastrum Antimonii and Unguentum Antimonii) may be used in the treatment of chronically enlarged joints, and formerly was applied to the back of the neck for the cure of epilepsy, meningitis, and other cerebral lesions.

Antimony is badly borne by children, by the aged, and by those who are enfeebled by disease. It should never be employed when gastro-intestinal irritation or inflammation is present.

Poisonous doses of tartar emetic depress the circulation, cause muscular relaxation, copious sweating, severe nausea, and gastro-intestinal pain. Violent vomiting and hiccough with copious watery stools resembling those of Asiatic cholera are present. The temperature becomes subnormal, the pulse running, rapid, and thready, the face pinched and livid, the body covered with a cold, clammy sweat, and the respirations faint and shallow. Cramps in the calves of the legs usually follow abstraction of fluids from the tissues by the excessive purging. Cutaneous eruptions, partial anæsthesia, fainting, loss of sensation, and convulsions sometimes intervene before death occurs.

The treatment of tartar emetic poisoning consists, first, in the application of external heat and irrigation of the stomach with a solution of tannic acid. The employment of morphine hypodermically for the relief of pain, and the use of respiratory and circulatory stimulants, such as alcohol, strychnine, atropine, and digitalis, should not be forgotten.

Patients recovering from the acute symptoms of this poisoning frequently die subsequently from fatty degeneration of the viscera. Chronic poisoning sometimes results from the frequent administration of this drug, The principal symptoms are nausea, vomiting, purging, cachexia, and death from exhaustion. Fatty degeneration is frequently found after death as well as intense venous congestion, dark fluid blood, and pulmonary congestion and gastro-intestinal irritation.

As a circulatory quieter, tartar emetic is given in doses of from $\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003–0.005 Gm.); as an expectorant and diaphoretic, from $\frac{1}{12}$ to $\frac{1}{8}$ grain (0.002–0.008 Gm.), every 3 or 4 hours. As an emetic, the dose is from $\frac{1}{2}$ to 1 grain (0.03–0.06 Gm.), every 15 minutes, until several doses are taken or until emesis occurs.

ANTIMONII OXIDUM, *Br.*—Antimony Oxide.

Stibium oxydatum.—Antimony Trioxide, Antimonous oxide, E.; *Oxyde d'antimoine,* Fr.; *Antimonoxyd,* G.; *Oxido de antimonio,* Sp.

Formula, $Sb_2O_3(Sb_4O_6)$. Molecular weight, 286.24.

Origin.—Oxide of antimony in an impure form was known to the alchemists of the Middle Ages. The term *flores antimonii* was at first chiefly applied to the product obtained by the burning of the black sulphide, but subsequently to the purer white powder resulting from the burning of metallic antimony in air. The mineral *valentinite* or *white antimony* consists of this oxide; *antimony ochre* or *cervantite* is antimonous-antimonic oxide.

Preparation.—The process as outlined in the British Pharmacopœia is, to pour a solution of antimonous chloride into a large bulk of water, thus forming the oxychloride or powder of Algaroth, $4SbCl_3 + 5H_2O = Sb_4O_5Cl_2 + 10HCl$, and to decompose the oxychloride with sodium carbonate.

The process formerly official in the U. S. (1870) was essentially the same as the above, except that directions were also given for preparing a solution of antimonous chloride by digesting 4 parts of black antimony sulphide with 18 parts of hydrochloric acid: $Sb_2S_3 + 6HCl = 2SbCl_3 + 3H_2S$. The oxychloride formed by decomposition was decomposed by ammonia water. The resulting antimonous oxide must be dried at not too elevated a temperature, to avoid the formation of higher oxides of antimony. A contamination with arsenous acid, resulting from the arsenic sulphide frequently present in the black antimony, need not be apprehended; the greater part of it will be expelled

during the first part of the operation as arsenic chloride, and what little may be left in the liquid will remain in solution on precipitating with water. The large quantity of noxious gases given off renders it necessary to operate under a hood or to dispose of the gases by consuming them in a furnace.

On heating metallic antimony in a loosely covered crucible the metal burns at a red heat when in contact with air to antimonous oxide, and this sublimes in glossy, transparent, or white needles, intermixed with octahedrons; this product was formerly distinguished as *flores antimonii (flowers of antimony)*. The oxide was dropped in the U. S., 1900.

Properties.—Antimonous oxide is a dense white or grayish-white powder, which is very sparingly soluble in water, insoluble in alcohol, ether, and nitric acid, but dissolves readily in hydrochloric acid; it is also soluble in a warm solution of tartaric acid or in a boiling solution of acid potassium tartrate. It is without odor and taste, and melts at a dull-red heat to a yellowish liquid, and at a full-red heat sublimes in crystals, as stated above; slow sublimation gives mainly octahedrons, while rhombic prisms are obtained by rapid heating. When the oxide is slowly heated in contact with air, it is converted into grayish, infusible, and non-volatile tetroxide, or *antimonous-antimonic oxide*, Sb_2O_4 or $Sb_2O_3.Sb_2O_5$. When heated with sodium hydroxide upon charcoal by means of the blowpipe, very brittle metallic globules are obtained. Its solution in hydrochloric acid dropped into water yields a white precipitate, and this is at once changed to orange-red by hydrogen sulphide.

Tests.—A solution of antimony oxide in hydrochloric acid, diluted with water to incipient permanent turbidity, will yield with hydrogen sulphide a precipitate which when thoroughly washed should be perfectly soluble in ammonium sulphide solution, to indicate the absence of lead and copper. In a dilute (1 per cent.) aqueous solution made with aid of tartaric acid, sulphates would be detected by barium chloride solution, chlorides by silver nitrate, and iron and other metals by potassium ferrocyanide. Arsenic may be detected by adding 1 Cc. of stannous chloride test-solution to a solution of 1 Gm. of the oxide in hydrochloric acid; no turbidity or coloration should ensue within 1 hour. 0.5 Gm. dissolved in 1 Gm. of cream of tartar in hot solution and then made alkaline with 3 Gm. of sodium bicarbonate, should require 70 Cc. of iodine solution for titration, corresponding to 100 per cent. (Br.).

Action and Uses.—Oxide of antimony is said to possess the general properties of other antimonial preparations, but because of its inferior solubility is less liable to produce nausea and vomiting. It is rarely employed in medicine, but may be given in doses of from 2 to 4 grains (0.12–0.25 Gm.).

ANTIMONII SULPHIDUM.—Antimony Sulphide.

Stibium sulfuratum nigrum, P. G.; *Antimonium crudum—Black (crude) antimony, Antimony trisulphide, Antimonous sulphide*, E.; *Sulfure d'antimoine, Antimoine cru, A. sulfuré*, Fr.; *Schwefelspiessglanz, Spiessglanz, Schwefelantimon*, G.; *Trisulfuro di antimonio*, F. It.; *Sulfuro de antimonio*, Sp.

Formula, Sb_2S_3. Molecular weight, 334.09.

It is found native as *stibnite*, gray antimony ore, or black antimony, and associated with galena, iron pyrites, quartz, and heavy spar, in various parts of Europe, Borneo, New Brunswick, Nevada, and in Sevier Co., Ark. It was known to the ancients as "stimmi," and was early employed as an external remedy in cutaneous diseases and for darkening the eyebrows and eyelashes. From the infusible ores with which it is associated it is freed by fusion in pots arranged in such a manner that the fused sulphide runs off into earthen vessels, where it cools. It is afterward powdered. Antimony trisulphide, being the commonest and cheapest antimony ore, is employed for preparing the metal and as the source of all compounds of antimony.

Properties.—Thus purified, it is known in commerce as crude antimony, and contains variable small quantities of iron, and often traces of arsenic, lead, and copper, all in the state of sulphides. It is steel-gray, of a metallic luster and a radiated crystalline texture, friable, soft, and leaving a black mark upon harder bodies. Its specific gravity varies between 4.6 and 4.7, it being but little lighter than black oxide of manganese, from which it is readily distinguished by the ready fusibility of splinters of antimony sulphide when held in the flame of a candle. It is inodorous and tasteless, and insoluble in simple solvents. At a temperature below a red heat it fuses to a dark-brown liquid. It is

frequently seen as a heavy black or grayish-black and somewhat shining powder. This when boiled with 10 parts of hydrochloric acid, dissolves without leaving more than 1 per cent. of residue. The solution, completely deprived of hydrogen sulphide by boiling, when added to water gives a white precipitate which is soluble in a solution of tartaric acid. After separation of the precipitate by filtration the filtrate gives an orange-red precipitate with hydrogen sulphide test-solution.—U. S., 1890.

Action and Uses.—Because of its uncertain physiological action, this preparation should not be employed in general medicine. It has been recommended as a diaphoretic, alterative, and cathartic in the treatment of strumous, scrofulous, and syphilitic conditions. In America it is occasionally employed in veterinary practice. The dose is stated to be from 5 to 15 grains (0.30–1 Gm.), either in powder or pill.

ANTIMONII SULPHIDUM PURIFICATUM.—Purified Antimony Sulphide.

Antimonium nigrum purificatum, Br.; *Purified black antimony*, E.; *Sulfure d'antimoine depuré*, Fr.; *Gereinigtes Schwefelantimon*, G.

Formula, Sb_2S_3. Molecular weight, 334.09.

Preparation.—Very finely divided antimony sulphide is macerated during 5 days, with frequent agitation, with half its weight of ammonia water, washed by repeated decantation with water, and dried by gentle heat. The object of this treatment is to remove arsenic, etc. The Br. process is practically identical with the above. Garot has shown that the ammoniacal liquid, when evaporated, leaves a red residue which contains very little arsenic. Arsenous sulphide is, however, freely soluble in *ammonium carbonate*, which dissolves but little antimonous sulphide. The process devised by Hager is as follows: Mix in a high vessel 1000 parts of levigated antimony sulphide with 100 parts of ammonia water, specific gravity 0.960, and sufficient warm water to permit the mixture being readily stirred; digest for a day at between 30° and 40° C. (86° and 104° F.), add 50 parts of official ammonium carbonate, again digest with frequent agitation for 48 hours, then dilute with water, and wash thoroughly. It forms a dark-gray or grayish-black lusterless powder having the properties mentioned under Antimony Sulphide. This as well as the crude sulphide were dropped in the U. S., 1900.

Tests.—Commercial antimony sulphide is sometimes adulterated with coal-dust, or mixtures of powdered coal and chalk are sold in place of it. The latter effervesce briskly with dilute hydrochloric acid, forming a solution containing calcium chloride. If 2 Gm. of the sulphide be mixed and cautiously ignited in a porcelain crucible with 8 Gm. of pure sodium nitrate, and the fused mass boiled with 25 Cc. of water, there will remain a residue which should be white or nearly so, and not yellowish nor brownish (absence of other metallic sulphides). On boiling the filtrate with an excess of nitric acid until no more nitrous vapors are evolved, then dissolving in it 0.1 Gm. of silver nitrate, filtering again if necessary, and cautiously pouring a few drops of ammonia water on top, not more than a white cloud, but no red nor reddish precipitate, should appear at the line of contact of the two liquids (absence of more than about 0.1 per cent. of arsenic).—U. S., 1890.

Action and Uses.—Purified sulphide of antimony is employed for the same purposes as sulphide of antimony (see ANTIMONII SULPHIDUM).

ANTIMONIUM.—ANTIMONY.

Stibium.—Antimoine, Fr.; *Antimon, Spiessglanzmetal*, G.

Symbol, Sb. Atomic weight, 119.3.

Antimony occurs in several mineral forms, but principally as trisulphide, known as *stibnite* or *antimony blende*, which occurs in large crystals of great beauty, especially in Japan. The sulphide was used in early times as a toilet article for darkening eyebrows. The metal was prepared as early as 1000 B. C. by the Chaldeans (W. Black). Its compounds were especially studied by Basil Valentine in the fifteenth and by Proust and Berzelius in the nineteenth century. France and Germany produce the bulk of antimony on the market. The best quality, in planoconvex cakes, comes from France. English and Spanish antimony comes in cones and pigs, respectively. The metal is obtained by heating the crude oxide (obtained by roasting the sulphide) with potassium hydroxide and charcoal. Such antimony is always impure, containing small amounts of iron, lead,

arsenic, and sulphur. Arsenic is removed by melting the metal repeatedly with $\frac{1}{10}$ its weight of niter, whereby potassium arsenate is formed in the slag. It is a hard, brittle, easily fusible, bluish-white metal of high luster and specific gravity 6.7. It is unaffected in air at ordinary temperature, but burns at a high temperature to the oxide, $Sb_2O_3(Sb_4O_6)$. The proper solvent for antimony is *aqua regia*. Sulphur, halogens, phosphorus, and arsenic unite with it directly in the cold or on heating. It enters into many alloys, 2 of which are *type-metal* and *Britannia metal*. In its chemical behavior it resembles phosphorus and arsenic very much, the 3 elements forming a natural group.

Action and Uses.—Antimony is never employed in medicine, and its various oxides, as a rule, should not be. For action and uses of antimony arsenate, see ARSENI TRIOXIDUM.

Oxides.—Antimony forms three oxides, $Sb_2O_3(Sb_4O_6)$, Sb_2O_4, and Sb_2O_5.

Antimonous Oxide, Sb_2O_3, or more properly, Sb_4O_6, has been described. It is a weak acid anhydride, and with alkalies gives salts of metantimonous acid or metantimonites, $KSbO_2$, but it acts more commonly as a basic oxide, giving salts with acids.

Antimony Tetroxide, Sb_2O_4, is formed when either antimony, the trioxide, or the pentoxide, is heated in the air at a dull-red heat for a long time. Phosphorus and arsenic do not behave thus. It is non-volatile.

Antimony Pentoxide, Sb_2O_5, formed by treating antimony or the preceding oxides, with concentrated nitric acid. It is a lemon-yellow powder insoluble in water. As in the case of phosphorus pentoxide, 3 acids derived from Sb_2O_5 exist, namely, ortho-, meta-, and pyro-antimonic acid, or H_3SbO_4, $HSbO_3$, and $H_4Sb_2O_7$. These acids are sparingly soluble in water, but dissolve in alkalies, forming the corresponding salts. One of these salts, $Na_2H_2Sb_2O_7$, acid sodium pyroantimonate, is interesting because of its insolubility; the corresponding potassium salt is soluble, $K_2H_2Sb_2O_7$.

Other oxides of antimony, more or less pure or combined with antimony sulphide, were formerly employed in medicine, and are occasionally, though very rarely, called for. When black antimony sulphide is gradually heated to redness in contact with the air, it is partly oxidized to antimonous antimonate, $Sb_2O_3Sb_2O_5$, and constitutes then an ash-gray powder known as *cinis antimonii* (*antimony ash*). When this is fused with a little black antimony, a transparent garnet-red mass, known as *vitrum antimonii* (*antimonial glass*), is obtained. When a mixture of equal parts of black antimony and potassium nitrate is deflagrated by igniting it in small quantities, it yields *hepar antimonii* (*liver of antimony*); and when this is exhausted with water to remove potassium sulphate and sulphantimonate, *crocus of antimony* is left, which is mainly a mixture of antimony oxide and sulphide. *Antimonium diaphoreticum* (*diaphoretic antimony*) is prepared like liver of antimony, except that more (2 parts) of potassium nitrate is used, so that the preparation contains, besides antimony oxide, antimonate, sulphate, nitrate, and nitrite of potassium in varying proportions. By washing this with water the residue consists mainly of *potassium antimonate*, which is recognized by the French Codex.

Antimony Trichloride, *Butter of antimony*. $SbCl_3$.—Formed by the action of chlorine on excess of antimony, by distilling a mixture of antimony and mercuric chloride, or by dissolving antimony trisulphide in hydrochloric acid, then concentrated solution of the chloride, usually colored by iron, and finally pure chloride, solidifying in fine white crystals, pass over into the condenser in succession. The crystals attract moisture and pass into a soft, butter-like mass; it is corrosive. Water breaks it down into an oxychloride (*powder of Algaroth*), and finally into the oxide, Sb_2O_3. It was recognized in the Br. P. of 1885 as Liquor Antimonii Chloridi, but has been dropped from the 1898 pharmacopœia.

Antimony Triiodide, SbI_3.—Obtained by heating antimony and iodine in a flask in the proportion of 3 atoms of iodine to 1 of antimony, cooling, and powdering the mass. A dark orange-red powder, decomposed by water.

Antimony Arsenate.—A heavy snow-white powder, said to be used in Russia as an alterative, 4 times daily in doses of $\frac{1}{50}$ grain (0.0012 Gm.). It contains 44 per cent. of arsenic acid.

For Antimonetted Hydrogen, SbH_3, and tests for antimony, see under ARSENI TRIOXIDUM.

ANTIMONIUM SULPHURATUM, *Br.*—Sulphurated Antimony.

Kermes mineral, E.; *Sulfure d'antimoine précipité*, Fr.; *Gefälltes Schwefelantimon*, G.; *Sulfuro de antimonio hidratado*, Sp.

Chiefly antimonous sulphide (Sb_2S_3; 335.14), with a very small amount of antimonous oxide (U. S., 1890). This preparation has been dropped in the U. S., 1900.

According to the Br. P., it is a mixture of antimonous sulphide and oxide, antimonic sulphide and oxide, and sulphur.

Origin.—Both antimonial kermes and golden sulphur appear to have been first obtained by Basilius Valentinus in the fifteenth century. The latter was called *sulphur*

auratum by Quercetanus (1603). The former was prepared by Glauber by dissolving black antimony in potassium hydroxide solution and cooling, and was lauded by Simon (1719) under the name of *alkermes minerale.* Numerous processes for obtaining these preparations have been published, nearly all of them resulting in mixtures of one or both sulphides of antimony with more or less antimonous oxide. The German Pharmacopœia recognizes only pure Sb_2S_5 under the title Stibium sulphuratum aurantiacum (Goldschwefel). See Antimonii Pentasulphidum, page 191.

Preparation.—Purified antimony sulphide in very fine powder, 100 Gm.; solution of sodium hydroxide, 1200 Cc.; distilled water, diluted sulphuric acid, each a sufficient quantity. Mix the antimony sulphide with the solution of sodium hydroxide and 3000 Cc. of distilled water, and boil the mixture over a gentle fire for 2 hours, constantly stirring, and occasionally adding distilled water so as to preserve the same measure. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, diluted sulphuric acid so long as it produces a precipitate. Wash the precipitate with hot distilled water until the washings are at most but very slightly clouded by test-solution of barium chloride, then dry the precipitate and rub it to a fine powder.—U. S., 1890. If avoirdupois weight be used, $3\frac{1}{3}$ ounces of antimony sulphide will require $40\frac{1}{2}$ fluidounces of solution of sodium hydroxide and $6\frac{1}{2}$ pints of distilled water.

The British process is as follows: 2 parts of *antimonous sulphide,* 2 parts of sublimed sulphur, and 1 part of commercial caustic soda are boiled together for 2 hours in 20 parts of water, then diluted while hot with 36 parts of hot water, filtered, and acidified before cooling with sulphuric acid. The precipitate is filtered, washed free from sulphates, and dried at not above 100° C. (212° F.). The changes here are approximately expressed thus: $Sb_2S_3 + 3Na_2S + S_2 = 2Na_3SbS_4$. The sodium sulphide, Na_2S, is formed by the action of S on NaOH. Na_3SbS_4, sodium sulphantimonate, is also known as *Schlippe's salt.* The acid added acts thus: $2Na_3SbS_4 + 3H_2SO_4 = Sb_2S_5 + 3H_2S + 3Na_2SO_4$. The pentasulphide, Sb_2S_5, is not pure, but contains some oxides and trisulphide, due to the presence of antimonite, antimonate, and sulphantimonite of sodium.

In the former U. S. P. process the solution contains both sulphantimonite and antimonite of the alkali, the formation of which is seen from the following equation: $Sb_2S_3 + 4NaOH = NaSbO_2$ (meta-antimonite) $+ Na_3SbS_3$ (ortho-sulphantimonite). On adding sulphuric acid, both the compounds named are decomposed and antimonous sulphide is precipitated without the evolution of hydrogen sulphide: $NaSbO_2 + Na_3SbS_3 + 2H_2SO_4 = Sb_2S_3 + 2Na_2SO_4 + 2H_2O$. The precipitate, however, is likely to retain a portion of undecomposed antimonite, which, if remaining in the hot acidulated liquid, is gradually decomposed; to insure this decomposition, Liebig suggested to pour the hot alkaline solution into an excess of diluted sulphuric acid, and to boil the moist precipitate with a fresh portion of such acid.

Properties and Tests.—Sulphurated antimony is a reddish-brown (dull-red, Br.) powder, without odor or taste, and insoluble in water and other simple solvents. Heated in a dry test-tube, it emits moisture and leaves a black residue. When heated with 10 times its weight of official hydrochloric acid it is nearly all dissolved, with evolution of hydrogen sulphide. The residue, after having been washed and dried, burns with the characteristic flame of sulphur and leaves a scanty ash. The solution in hydrochloric acid, when added to water, deposits a white powder. The liquid filtered from this powder yields an orange-red precipitate with hydrogen sulphide. Water in which the preparation has been boiled should not yield a white precipitate with ammonium oxalate (absence of calcium). A mixture of 1 part of sulphurated antimony and 20 parts of hot water, well shaken, should yield a filtrate which is neutral to test-paper, and which should not be rendered more than slightly opalescent by barium chloride test-solution (limit of sulphate) or silver nitrate test-solution (limit of chloride).—U. S., 1890. The limit allowed by the U. S., 1890, for arsenic is the same as prescribed in the case of purified black antimony (which see). Boiled in water with acid potassium tartrate, the resulting solution is precipitated orange red with hydrogen sulphide, thus showing the presence of antimonous oxide. Oxidized with nitric acid, 3 Gm. give a white residue of 2 Gm. when dried and heated to redness (Br.).

Action and Uses.—Kermes mineral is rarely employed in medicine at the present time. It was formerly largely used as an alterative, diuretic, and emetic, but at present other more potent remedies are used in its place. The dose is from 1 to 2 grains

(0.05–0.10 Gm.), twice daily as an alterative, and from 5 to 20 grains (0.30–1.3 Gm.) as an emetic.

Allied Compounds.—Antimonii Oxysulphuretum, U. S., 1870.—*Stibium sulfuratum rubrum*, P. G., 1872, *Sulphur stibiatum rubrum, Kermes minerale, Kermes aurificum minerale.—Oxysulphuret of antimony, Kermes mineral*, E.; *Sulfure d'antimoine hydraté, Kermès minéral, Poudre des Chartreux*, Fr.; *Mineralkermes*, G.—The name "Kermes" mineral was applied by the U. S. P., 1890, to the sulphurated antimony (see above). Composition, a mixture of Sb_2S_3 and Sb_2O_3. This was prepared by boiling for 1 hour 1 part of black antimony with 250 parts of water containing 23 parts of sodium carbonate, filtering and cooling; after 24 hours the precipitate was collected, washed with cold water previously boiled, and dried. The reaction is similar to that described above, except that carbon dioxide is given off. On cooling, a mixture of Sb_2S_3 and Sb_2O_3 is deposited, varying with the relative proportion of the sulphide and carbonate, and with the concentration of the liquid.

Antimonii Pentasulphidum.—*Antimonii sulphuretum aureum s. præcipitatum, Stibium sulfuratum aurantiacum*, P. G.; *Sulphur stibiatum aurantiacum, Sulphur auratum antimonii.—Antimonic sulphide, Golden sulphuret of antimony, Golden sulphur*, E.; *Soufre doré antimoine*, Fr.; *Goldschwefel, Sulfaurat*, G.—This was originally prepared by precipitating an aqueous solution of liver of antimony with an acid, and contained, besides Sb_2S_5, also variable amounts of Sb_2S_3 and Sb_2O_3. Instead of such mixtures, the German and other pharmacopœias now recognize the pure antimonic sulphide, which is prepared as follows: A solution of 70 parts of crystallized sodium carbonate in 250 parts of water is boiled, and mixed with milk of lime containing 26 parts of lime and 80 parts of water. 36 parts of levigated antimony sulphide and 7 parts of sublimed sulphur are added, and the whole boiled until the gray color has disappeared, when the liquid is filtered and crystallized. 24 parts of these crystals, which, from the discoverer, Schlippe (1821), are known as *Schlippe's Salt*, and have the composition $Na_3SbS_4 + 9H_2O$, are dissolved in 700 parts of water, and added to a mixture of 9 parts of sulphuric acid and 200 parts of water. The precipitate, having the composition Sb_2S_5, is washed and dried. The reactions involved in this process may be illustrated by the following equations: (1) $4Sb_2S_3 + 9(Na_2CO_3 10H_2O) + S_8 + 9CaO = 5(Na_3SbS_4 9H_2O) + 3(NaSbO_3) + 9CaCO_3 + 45H_2O$. (2) $2(Na_3SbS_4 9H_2O) + 3H_2SO_4 = Sb_2S_5 + 3(Na_2SO_4) + 3H_2S + 18H_2O$. It is an orange-colored, inodorous, and tasteless powder, which, on being slowly heated in a test-tube, gives a sublimate of sulphur, leaving a residue of black antimonous sulphide; at a red heat it is completely volatilized. Arsenic is tested for by treating 0.5 Gm. of the powder with 5 Cc. of a saturated solution of ammonium carbonate at a temperature of 50°–60° C. (122°–140° F.) with repeated shaking. On acidifying the filtrate with hydrochloric acid, no yellow precipitate should occur within 6 hours. The limits of sulphate and chloride are tested for by adding silver nitrate and barium nitrate solutions, respectively, to water which has been shaken with the powder; no turbidity should occur immediately.—P. G.

ANTIPYRINA, *U. S.*—Antipyrine.

Phenazonum, Br.; *Pyrazolonum phenyldimethylicum*, P. G.; *Analgésine*, Fr. Cod.; *Phenazone, Methozine, Analgesine, Dimethyl-phenyl-iso-pyrazolone, Dehydrodimethyl-phenylpyrazine*, E.; *Antipyrine, Anodynine, Parodyne*, Fr.; *Antipyrin, Phenyldimethyl-pyrazolon*, G.

Formula, $C_{11}H_{12}N_2O$ or $C_3HN_2O(CH_3)_2.C_6H_5$ or $C_6H_5N.CO.CH:C(CH_3).N(CH_3)$. Molecular weight, 186.75.

Origin and Preparation.—Antipyrine was first prepared by L. Knorr (1883), and afterward introduced to the medical profession by Filehne. Several processes are in use for the manufacture of antipyrine, of which the following is probably the best known: Phenylhydrazine, $C_6H_5HN.NH_2$, is heated with aceto-acetic ether, $CH_3CO.CH_2O.OC_2H_5$, whereby phenylmethylisopyrazolone, $C_6H_5N.CO.CH:C(CH_3).NH$, is produced. If this compound be dissolved in methyl alcohol and treated with methyl iodide, the latter unites with it to form an addition-compound, which when further treated with a solution of sodium hydroxide splits off hydriodic acid and separates antipyrine in the form of a heavy oil. The latter may then be crystallized from toluene or ether. Antipyrine may also be obtained direct by heating methylphenylhydrazine with aceto-acetic ether, water and alcohol being split off; thus, $C_6H_5HN.NHCH_3 + CH_3CO.CH_2CO.OC_2H_5 = C_6H_5N.CO.CH:C(CH_3).N(CH_3) + H_2O + C_2H_5OH$.

Properties and Tests.—Antipyrine crystallizes readily in laminæ, or from water in rhombic prisms. The commercial article is a voluminous crystalline white or whitish powder; it is almost inodorous, and has a mild bitter taste. At 25° C. (77° F.) it dissolves in less than 1 part of water, in about 1 part of alcohol or chloroform, and in about 30 (40, Br.) parts of ether, and is freely soluble in benzene, but slightly soluble in benzin. 2 Cc. of a 1 per cent. solution acquire with 2 drops of fuming nitric

acid a green color, changing to red on the addition of another drop of the acid to the previously boiled liquid. 1 drop of ferric chloride solution, added to 2 Cc. of a 0.1 per cent. solution of antipyrine, causes a deep-red color, changing to pale yellow on the addition of 10 drops of sulphuric acid. A solution of tannic acid added to a 1 per cent. aqueous solution of antipyrine causes a copious white precipitate of antipyrine tannate. The solution of antipyrine in water should have a neutral reaction, should be colorless, should not have an acrid taste, and should not be affected by hydrogen sulphide. It should volatilize completely when heated. On warming 0.1 Gm. of antipyrine with sodium hydroxide test-solution, and again warming after the addition of chloroform, the disagreeable odor of phenyl isocyanide should not be developed (absence of acetanilide). 0.1 Gm. of sodium nitrite and 12 Cc. of a 1 per cent. aqueous solution of antipyrine yield a nearly colorless liquid which turns deep green on addition of 1 Cc. of diluted sulphuric acid, due to formation of isonitroso-antipyrine. An aqueous solution of the same strength mixed with an equal volume of nitric acid assumes a yellow color, passing to crimson on warming (distinction from acetanilide and acetphenetidin).—U. S. 0.2 Cc. of a 1 per cent. aqueous solution should be colored green by 2 drops of fuming nitric acid, and the color should be changed to red by boiling with an additional 3 or 4 drops of the acid. A 5 per cent. aqueous solution gives with mercuric chloride test-solution a white precipitate which disappears on boiling, but reappears as the liquid cools.—Br.

Antipyrine melts at 113° C. (235.4° F.), and when further heated turns red, then brown, and acquires an empyreumatic odor resembling oil of amber, the residue being soluble in alcohol, and with a red color in chloroform. The powder as well as the solution should carefully be protected from contact with iron compounds.

Acetanilide has been found mixed with antipyrine; its detection is easy, for although both compounds have approximate melting-points (113° C., 235.4° F.), a mixture of equal parts melts at 45° C. (113° F.) (Helbing). Antipyrine is a well-characterized base, and forms salts with acids by direct addition. Many drugs have been found incompatible with it, among which may be mentioned sodium bicarbonate and salicylate in solid form, chloral hydrate and butylchloral hydrate, hydrocyanic acid, ferrous sulphate, carbolic acid, mercuric and mercurous chlorides, and all nitrites in acid solution.

Action and Uses.—Antipyrine was first introduced and indiscriminately employed in medicine for the reduction of high fevers, but because of the untoward symptoms which it frequently causes, and the fact that it in no way shortens the course or modifies the other symptoms of infectious febrile conditions, it has largely fallen into disuse. While it has been fully established that antipyrine is not a remedy to be employed in the routine treatment of febrile diseases, it has been definitely ascertained that its properties as an analgesic are equal to those of any other drug, with the exception of opium, and as such it is now very largely employed. Medicinal amounts have little or no effect upon the cerebral cortex, but overdoses cause tetanic and epileptiform convulsions while consciousness is preserved. Its primary action upon the cord is that of a stimulant, but later it depresses especially its sensory portions, and decreases reflex activity. Antipyrine depresses the sensory nerves and, to some extent, both the motor nerves and the muscles. Locally applied to mucous membrane, or when injected subcutaneously, it produces local anæsthesia which lasts for several days. In medicinal amounts phenazone, as it is sometimes called, has practically no influence upon the circulation, unless it has been already enfeebled by previous disease. It may be looked upon as a cardiac depressant, however, rather than as a stimulant, but it is probably true that many cases of so-called circulatory failure following its administration have been collapse resulting from the great lowering of temperature rather than from any direct effect of the drug upon the heart. Very large doses and toxic amounts do decrease arterial tension, unless convulsions occur, when it is raised. The lowering of blood-pressure is probably due both to its action upon the heart muscle and upon the bloodvessels. No material changes occur in the blood from medicinal doses of this drug, but where idiosyncrasy exists cyanosis may come on. Toxic amounts decrease the oxygen-carrying power of the blood, reduce the oxyhæmoglobin to methæmoglobin, cause shrivelling of the red blood-corpuscles, and the appearance of hæmatin in the urine. Small doses of the drug have no effect upon respiration, but very full doses increase its rapidity, while lethal amounts cause death by respiratory paralysis. In fevered states antipyrine acts as a fairly constant antipyretic by increasing the elim-

ination and decreasing the production of bodily heat. In the healthy individual it has little or no effect upon temperature unless given in toxic amounts, when it acts as a depressant. Phenazone is absorbed and eliminated rapidly. Its elimination takes place chiefly by the kidneys, but it has been found in the salivary secretion and in the milk of nursing women. It acts as a conservator of tissue, and decreases both the watery and nitrogenous portions of the urine. This drug is also antiseptic, and small quantities prevent fermentation and putrefaction, while larger amounts will destroy micro-organisms.

It is now generally conceded that antipyrine is not a drug to employ in the routine treatment of fevers. It may be an advisable remedy to use in the hyperpyrexia occasionally seen in scarlet fever, smallpox, pneumonia, and other dynamic states, but the condition of the circulation frequently contraindicates its use, especially in pneumonia. When employed for this purpose, it should usually be given in one or two full doses, and not in small ones frequently repeated. The application of cold (see Cold Water) is a much better routine treatment, as it not only reduces temperature, but also stimulates all the vital functions of the organism, while this drug as a rule depresses them. It is inadvisable to use antipyrine in enteric fever and other typhoid conditions, as it acts as a depressant and in its elimination increases the work of the kidneys, which are already burdened by the toxins which they excrete. It is not advisable to employ this drug either in sunstroke or in pulmonary tuberculosis, for in the former it frequently fails to reduce the temperature, and in the latter it commonly increases the night-sweats and sometimes causes collapse. In the various forms of nerve pain antipyrine is the peer of all other drugs, but it is valueless in pain resulting from disease of the internal organs, surgical operations, or inflammations. It is remarkably efficient in the treatment of migraine, the lancinating pains of locomotor ataxia, in sciatica, and in various neuralgias resulting from nervous depression or antecedent disease. It relieves the pain of gout and rheumatism, and is said to shorten the course of the latter condition; but as it frequently increases the sweating in acute rheumatism, it should be given guardedly. It has been recommended to palliate the pains of labor and to relieve dysmenorrhœa, but its employment in these conditions is not attended with marked success. Diabetes mellitus, depending upon a gouty diathesis, is said to have been cured by its administration. While it controls in a marked degree the febrile paroxysms of malaria, it in no way acts as an antiperiodic. Antipyrine is serviceable in the treatment of minor spasmodic conditions depending upon nervous irritability. It is the best remedy to employ in whooping-cough, and spasmodic croup and laryngeal spasm are said to have been relieved by it. It is beneficial in epileptic convulsions resulting from reflex irritation, such as that caused by intestinal worms or dysmenorrhœa, and is occasionally serviceable in idiopathic epilepsy, and especially so when combined with the bromides.

Local applications of a 4 per cent. solution are valuable in the treatment of acute coryza and in congestions of the larynx and pharynx. As these applications are quite painful, they should be preceded by one of cocaine. They relieve the congestion by contracting the capillaries with which they come in contact. Hypodermically, a solution may be injected into the region of a hypersensitive nerve, as in sciatica, for the purpose of causing local anæsthesia, but the pain immediately following is usually severe. Because of its power of constringing bloodvessels, antipyrin has been employed in 4 per cent. solution as a hæmostatic agent, and is of service in the treatment of epistaxis and other similar hemorrhages.

Medicinal amounts of antipyrine sometimes cause duskiness of the face, coldness of the extremities, sweating of the face, and tingling of the skin. Various skin eruptions, such as erythematous patches, pemphigus-like spots, urticaria, dermatitis, and large bullæ, have been noted. These symptoms are usually of sudden onset, and disappear within a few hours. Poisonous doses, in addition to the above symptoms, occasion headache, vertigo, tremors, dyspnœa, excessive sweating, a rapid running pulse, lowering of the temperature, collapse, convulsions, and death from respiratory failure. This condition is treated by the application of external warmth to maintain bodily heat, and the use of respiratory and circulatory stimulants, such as strychnine, atropine, and digitalis. Oxygen inhalations may be given with benefit if cyanosis is marked.

The ordinary dose is from 3 to 5 grains (0.20–0.30 Gm.), either in powder, syrup, or aromatic water. As much as 20 grains (1.3 Gm.) may be given without detriment.

Derivatives of Antipyrine.—ACETOPYRINE.—This name is applied to a recent compound of antipyrine and aspirin (acetyl-salicylic acid). It occurs as a white crystalline powder, having a faint acetous odor and melting at 64°–65° C. (147.2°–148° F.). It is sparingly soluble in cold, but more soluble in hot water, and is readily dissolved by alcohol and chloroform; almost insoluble in ether.

ANTIPYRINE BENZOATE, known also as BENZOPYRINE. $C_{11}H_{12}N_2O.HC_6H_5O_2$.—It may be obtained by adding antipyrine to a boiling solution of benzoic acid. It is a yellow liquid which solidifies to a crystalline mass. Almost insoluble in hot and cold water, but soluble in alcohol and ether.

ANTIPYRINE-CAFFEINE CITRATE, *Migrainin.*—Obtained by fusing on a water-bath a mixture of 85 parts of antipyrine, 9 parts of caffeine, and 6 parts of citric acid. Upon cooling, the mass solidifies and is reduced to powder. Simple mixture of the ingredients by trituration will not answer, as it becomes pasty. It occurs as a colorless hygroscopic powder. As its name implies, migrainin is used in the treatment of migraine and other forms of headache. The dose is from 5 to 15 grains (0.30–1 Gm.).

ANTIPYRINE MANDELATE, *Tussol.* $C_{11}H_{12}N_2O.C_8H_8O_3$.—Prepared by heating a mixture of 188 parts of antipyrine and 152 parts of mandelic acid on a steam-bath, cooling the liquid mass, and crystallizing from alcohol. Colorless crystals, soluble in water and alcohol, having a bitter taste, and melting at 52°–53° C. (125.6°–126.4° F.). At higher temperatures it is decomposed, giving off an odor of oil of bitter almond, and finally burns without leaving a residue. A 5 per cent. aqueous solution is colored green by addition of a few drops of fuming nitric acid, and blood-red by addition of ferric chloride solution. If mixed with milk, the salt is decomposed. Tussol is recommended in the treatment of whooping-cough. The dose is from ½ to 10 grains (0.025–0.60 Gm.), varying with the age of the patient.

ANTIPYRINE SALICYLATE, *Salipyrine, Salazolon, Salipyrazolin.* $C_{11}H_{12}N_2O.HC_7H_5O_3$.—Obtained by heating on a water-bath a mixture of 57.7 parts of antipyrine and 42.3 parts of salicylic acid. An oily liquid results, which congeals on cooling and may be crystallized from alcohol. A colorless, odorless, crystalline powder of acid reaction and having a sweetish-bitter taste. It is soluble in 200 parts of cold and 25 parts of boiling water; also soluble in alcohol, ether, and chloroform. It melts at 92° C. (197.6° F.). Addition of ferric chloride solution to an aqueous solution of the salt causes the violet coloration characteristic of salicylic acid. Salipyrine possesses the combined properties of salicylic acid and antipyrine. Doses of 15 to 30 grains (1–2 Gm.) have been employed in rheumatic fever, chronic rheumatism, tonsillitis, and influenza.

ANTIPYRINE SALICYL-ACETATE, *Pyrosal.*—This compound was introduced by J. D. Riedel. Process of manufacture not given. It contains 50 per cent. of antipyrine and 37 per cent. of salicylic acid, and occurs in colorless leaflets or needles. It is sparingly soluble in water, and has a sour but not bitter taste. Pyrosal is analgesic, antipyretic, and antirheumatic. It has been recommended in the treatment of rheumatism in doses of 5 to 10 grains (0.30–0.60 Gm.) several times daily.

BUTYLCHLORAL-ANTIPYRINE. $C_{11}H_{12}N_2O.C_4H_5Cl_3O + H_2O$.—This compound is obtained by triturating together 188 parts of antipyrine and 193.5 parts of butylchloral hydrate until the mixture liquefies, dissolving the oily liquid in hot water, and setting aside to crystallize. It occurs in colorless needles, which melt at 70° C. (158° F.) and are soluble in 30 parts of water at ordinary temperature. Butylchloral-antipyrine is employed for the same purposes and in the same dose as hypnal.

CHLORAL-ANTIPYRINE.—Two combinations of hydrated chloral and antipyrine have been introduced into medicine. Of these,

MONOCHLORAL-ANTIPYRINE or HYPNAL is best known. It is made exactly like the preceding preparation, except that 165.5 parts of hydrated chloral are used in place of the butylchloral hydrate. Its composition is expressed by the formula: $C_{11}H_{12}N_2O.CCl_3CH(OH)_2$. It occurs in colorless octahedral crystals, which melt at 67°–68° C. (152.6°–153.4° F.) and are soluble in 30 parts of cold water. Hypnal is analgesic and hypnotic. It is employed in neuralgic insomnia and in that arising from the excessive cough of tuberculosis and bronchitis, in doses of 5 to 20 grains (0.30–1.30 Gm.).

DICHLORAL-ANTIPYRINE, $C_{11}H_{12}N_2O.[CCl_3CH(OH)_2]_2$, differs from the other compound in containing an additional molecule of hydrated chloral. It is made by the same process, except that only 94 parts of antipyrine are used with 165.5 parts of hydrated chloral. Dichloral-antipyrine is used for the same purposes and in the same doses as hypnal.

DIMETHYLAMIDO-ANTIPYRINE, *Pyramidon.* $C_{13}H_{17}N_3O$.—Prepared by reducing an acetic acid solution of isonitroso-antipyrine in alcohol to amido-antipyrine, and treating the latter with methyl chloride or iodine. It occurs as a crystalline powder of yellowish-white color and almost free from taste. It melts at 108° C. (226.4° F.) and is soluble in 10 parts of water. Pyramidon is readily distinguished from antipyrine by the following color reactions: If to an aqueous solution ferric chloride solution, nitrous acid, or fuming nitric acid be added, a fugitive violet-blue color will be produced in each case, instead of the respective red and green colorations as in the case of antipyrine. Pyramidon is said to possess the same physiological action as antipyrine, but its effect upon the nervous system is more powerful and more lasting than that of the latter remedy. It has been recommended in tuberculosis in doses not exceeding 8 grains (0.5 Gm.).

FERRIPYRINE. $(C_{11}H_{12}N_2O)_3Fe_2Cl_6$.—It is made by adding a solution of 5 parts of crystallized ferric chloride in 10 parts of 96 per cent. alcohol to a solution of 5 parts of antipyrine in 10 parts of alcohol and 50 parts of ether. The resulting orange-red precipitate is collected on a filter, washed with ether, and dried on porous tiles at 40° C. (104° F.). The compound occurs as a permanent, orange-red fine powder, containing 64 per cent. of antipyrine and 36 cent. of anhydrous ferric chloride, which is soluble in 5 parts of cold and 9 parts of boiling water. Upon heating a cold saturated solution ruby-red leaflets are separated, which melt at 225° C. (437° F.). It is insoluble in ether, but soluble in alcohol and benzene, and can be crystallized from its solution in methyl acohol. If alkali carbonates or bicarbonates be added to an aqueous solution of ferripyrine, ferric hydroxide is precipitated. Ferripyrine should be protected against light. Ferripyrine is employed both locally and in internal medicine. A 20 per cent. solution is recommended as a hæmostatic. It is usually employed upon cotton tampons. In doses of 5 to 10 grains (0.30–0.60 Gm.) it is said to be of value in the treatment of headache and neuralgia dependent upon anæmia.

FORMOPYRINE, *Methylenediantipyrine.* $(C_{11}H_{12}N_2O)_2CH_2.H_2O$.—Prepared by heating 5 parts of antipyrine with 4 parts of formalin (40 per cent. solution of formaldehyde) for 4–6 hours at a temperature of 120° C. (248° F.). Upon cooling, the resulting crystals are washed with water, dried, and recrystallized from benzene. The hydrated crystals melt at 156° C. (312.8° F.), but if anhydrous, at 177° C. (350.6° F.). It is insoluble in cold and sparingly soluble in hot water, but readily soluble in alcohol.

IODOPYRINE. $C_{11}H_{11}IN_2O$.—May be prepared by mixing 127 parts of iodine dissolved in 1500 parts of alcohol with a solution of 188 parts of antipyrine dissolved in 750 parts of alcohol, the mixture after several days separating crystals of iodopyrine, which consist of colorless silky prismatic needles, only slightly soluble in cold and readily soluble in hot water, and practically free from odor and taste. Iodopyrine melts at 160° C. (320° F.). Iodopyrine presents the combined physiological action of iodine and an antipyretic, and has been recommended in bronchial asthma and tertiary syphilis. The dose is from 10 to 20 grains (0.60–1.3 Gm.). After its administration the characteristic reaction of iodine may be found in the urine.

ANTITOXINS.

Since the antitoxins are the direct result of bacteriological research, it will afford a clearer understanding of the properties of these substances if a few paragraphs are devoted to a general consideration of the principles of bacteriology before dealing with the individual members of the group.

Bacteria were discovered by Leeuwenhoek more than 200 years ago, and were believed to be animalculæ until very recent years, when the researches of bacteriologists and botanists showed conclusively that they were minute unicellular plants closely related to the algæ, moulds, yeasts, etc., which undoubtedly belong to the vegetable kingdom. Bacteria are probably the most minute organisms in existence—indeed, they may be compared to atoms. Budjwid estimated that eight billions of pus germs would weigh but a single milligram.

Many methods of classifying bacteria have been proposed: as chromogenic or non-chromogenic, depending upon the formation of coloring-matter; pathogenic (disease-producing) and non-pathogenic, etc. The most important classification, and one that has generally been accepted, is based upon form. This classification gives us the micrococci, bacilli, and spirilla. The micrococci are spherical, and may have more comprehensive names denoting the grouping of the organisms: thus when occurring in irregular masses they are called staphylococci—*e. g.*, the ordinary pus germ, Staphylococcus pyogenes aureus; when two occur together, they are termed diplococci—*e. g.*, diplococcus of pneumonia; when a number of micrococci form long chains, they are spoken of as streptococci, as the streptococcus of erysipelas, tonsillitis, etc. The second class, bacilli (the word "bacillus" meaning a small rod), may occur in dense masses or singly, as the Bacillus tuberculosis, bacillus of typhoid fever, and many of the other common pathogenic bacteria, or these may form long threads, as in the case of anthrax. The third class, but a few species of which have been studied, are the spirilla, which, when occurring singly, have a comma or bent-rod shape. When several elements grow into long threads, spirals are formed, as in the case of the spirillum of Asiatic cholera.

No hard-and-fast lines can be laid down, as all these forms merge gradually one into another, in some cases a bacillus being so short as to be mistaken for a coccus. The grouping and shape of bacteria depend to a considerable extent upon environment; especially do variations of temperature, food, etc., produce changes. In many instances cultures when exposed to detrimental influences will change in a marked degree, involution-forms being produced which vary greatly from normal types—especially is this noticeable in cultures of diphtheria.

Some bacteria develop spores corresponding to the seeds of higher plants. The loca-

tion of these spores in the body of the organism may give the germ an atypical appearance. A good illustration is that of the tetanus germ, which, since the spore occurs at one end of the bacillus, presents the appearance of a short pin.

One of the most important properties of bacteria is the facility with which their protoplasm combines with the basic aniline dyes, which enables the observer to study with great accuracy variations in form, size, etc., and often to determine characteristics of the organism which would not be possible in unstained specimens.

Little is known relative to the structure of bacteria, notwithstanding the great amount of work devoted to this phase of the subject. They may be regarded as small bits of protoplasm with a transparent enveloping membrane. In some cases minute granules, especially in stained specimens, may be noted in the protoplasm. Bacteria probably, like other cells, contain a nucleus.

Many forms of bacteria possess the power of spontaneous motion, owing to the development of one or more whips or vibrios. The bacillus of typhoid fever is one of the best illustrations.

Bacteria usually multiply by fission, a constriction appearing in the middle of the organism, which gradually deepens until division takes place at that point. When the division is incomplete, chains are formed, as in the bacillus of anthrax. Under favorable conditions, since bacteria may divide once every 15 minutes, an incomprehensible number of germs may be produced in a short time.

The progeny of each different germ, when grown upon the surface of solid culture-media, usually forms a small round or nearly round speck, which is called a colony. Bacteria can grow only in the presence of moisture when supplied with proper food. Many of them, usually those producing diseases in animals, will multiply only when kept at the temperature of the animal body in which they occur. Since bacteria do not contain chlorophyll, they cannot assimilate carbon dioxide as do the higher plants; light hinders their growth to a considerable extent, hence the prevalence of disease in dark, damp localities. Most forms of bacteria require oxygen, and obtain it from the air. However, some germs, as the bacillus of tetanus, will not grow if oxygen be present; consequently in cultivating them artificially in the laboratory it is necessary to exclude air and supply hydrogen or some other gas to take the place of air in the containers in which they are grown.

Bacteria are not destroyed by extreme cold, but nearly all kinds are killed at a temperature of 100° C. (212° F.), if maintained for a considerable length of time.

Pathogenic bacteria require almost invariably neutral or slightly alkaline substances for food, since the animal tissues in which they occur are alkaline; while certain other germs thrive in a slightly acid medium.

In order to obtain a definite knowledge of the biological characteristics of bacteria, they must be grown in various ways. A great variety of substances have been employed as food; some of these are natural, others artificial. Of the natural varieties of pabulum, the most important is blood-serum obtained under aseptic conditions from the blood of slaughtered animals. This serum may be coagulated by heat (Koch's blood-serum), or when a small per cent. of beef bouillon is added before coagulation it is known as Loeffler's blood-serum, and is employed very generally for the cultivation of diphtheria germs. Potatoes, tuberous roots, milk, cooked fish, and various other substances may be employed. Usually, however, for laboratory purposes, culture-media having as a basis beef bouillon containiug 1 to 2 per cent. of peptone and 0.5 per cent. of sodium chloride are employed. The cultures of bacteria, which produce the substances employed for the production of the antitoxins, are usually grown in the bouillon itself. For solid and semisolid media, substances are added to the beef bouillon, such as gelatin, agar-agar, etc. In all cases it is necessary that extreme care be taken to supply each particular kind of bacteria with that culture-medium which allows growth to occur with the greatest rapidity and certainty. The artificial or natural culture-material, before it can be employed for experimental purposes, must be placed in suitable containers, usually test-tubes or flasks, the necks of which are plugged with cotton to prevent the entrance and exit of bacteria, and still allow air to pass in and out. The contents of the containers are rendered sterile by heating repeatedly on successive days in a steam sterilizer or autoclave.

Bacteria play a very important part in the cycle of life in splitting up complex organic substances into simpler ones. In the words of Pasteur, "putrefaction is a phe-

nomenon correlative of life, not of death." Carbon dioxide, alcohol, gases of the methane series, etc., are some of the products that may be formed during the disintegration of the carbohydrates. Proteids give origin to a still greater number of compounds before being returned to plants, as ammonia, nitrous acid, and other organic constituents. Many of the intermediate products may be of synthetic origin, as bacterial cells may elaborate organic compounds as well as the cells of the higher plants and animals. Many of these intermediate products are of the greatest practical importance to mankind. Ptomaines, bearing such a striking resemblance to the alkaloids of higher plants, are perhaps the best known, as many have been isolated. Still more poisonous than the ptomaines are the toxalbumins, many behaving chemically like albumins, others like globulins, belonging to the same class of poisons as the deadly ricin of the castor-oil bean, possibly also the venom of snakes; but the most toxic substances elaborated by bacteria do not give the reaction of proteids, and do not react in a characteristic manner to alkaloidal reagents, but are many times more poisonous than either. These substances, which have not been isolated in a pure state, are called toxins. It has been estimated that $\frac{1}{250}$ grain of impure tetanus toxin is sufficient to kill a full-grown man. One minim of a bouillon toxin of diphtheria has killed a horse weighing more than half a ton.

Many of the facts of immunity have been known since the earliest time. That individuals or races are less susceptible to certain diseases than others, has been the cause of inquiry as to the meaning of disease by physicians in all ages. Likewise, it has been the universal observation that one attack of an infectious disease renders a person immune to subsequent attacks of the same disease, or at least a second attack does not recur for some time after the patient has recovered.

Jenner, more than a hundred years ago, showed that the inoculation of cowpox virus would prevent smallpox.

Raynaud, in 1877, successfully protected a calf against cowpox by injecting it with blood from a calf that had been vaccinated.

Pasteur, in 1880 and subsequently, successfully prepared vaccines against some of the animal diseases by attenuating cultures with heat, and declared: "It is possible for man to eradicate every contagious disease from off the face of the earth."

In 1886, Salmon and Smith immunized pigeons against hog cholera by the previous injection of sterilized cultures of the bacteria producing this disease.

Roux, likewise, accomplished similar results by the use of attenuated anthrax and symptomatic anthrax cultures.

Loeffler immunized guinea-pigs against diphtheria by inoculating them with weakened cultures.

C. Fraenkel, in 1890, likewise published methods for producing immunity in animals against diphtheria.

Behring and Kitasato, one day later, published their method for immunizing against diphtheria and tetanus.

In 1891, Klempler brothers reported similar results with pneumonia.

It has been a long-observed fact that carnivorous animals that thrive on putrid flesh and decomposing substances are immune to many of the diseases that attack other types of animals.

In 1887, Sewell immunized pigeons against the venom of rattlesnakes. Hericourt and Richet, the same year, found that the blood from dogs treated with tubercle germs would protect unimmunized dogs.

Ogata and Jasuhara prevented the development of anthrax in mice by previous inoculations of blood from an animal immune to anthrax.

Behring and Kitasato, a little later, showed "that the blood of an animal, which had an acquired immunity against tetanus or diphtheria when added to a virulent culture of one or the other of these germs, neutralizes the pathogenic power of such cultures, as shown by inoculation of susceptible animals." Likewise, they showed that the filtrate obtained from bouillon cultures of diphtheria and tetanus could be rendered harmless by adding to them blood from an immune animal.

Ehrlich assisted greatly in this work by showing that rabbits could be immunized against the poisons abrin and ricin.

Nearly every prominent bacteriologist in Europe and America during the period from 1890 to 1894 was engaged in research which bore directly or indirectly upon the possibility of producing antitoxins. At the International Congress of Hygiene which met in October of that year at Budapest, Roux and Behring presented papers on the production

of immunity against diphtheria, on obtaining the curative serum, and clinical data that convinced the medical world that it was possible, by artificial means, to produce nature's remedy for the cure and prevention of diphtheria.

Many unsuccessful attempts have been made to isolate the antitoxins from the blood-serum and to determine their chemical composition. They are fairly stable bodies, since the serum may be heated to nearly the coagulation-point without destroying them. Various preservatives, as trikresol, phenol, etc., do not destroy them, and they remain active for many months. The antitoxins are removed from the serum by precipitation of the proteids, and nearly all the antitoxic strength disappears from the serum when the globulins are extracted, while the globulins are found to possess nearly as great antitoxic strength as the serum from which they were obtained.

A number of workers have contended that the antitoxins were toxins that had become altered by passage through the animal body, but this belief has been contradicted by Roux and others. The belief that antitoxin is an enzyme likewise remains to be established as a fact. Ehrlich's "lateral chain theory" has been most generally accepted as the best explanation. According to this view, the animal cells are regarded as very complex molecular bodies, having many "lateral chains" of different combining powers. These cells, when stimulated by various substances of animal, vegetable, or bacterial origin, which may be introduced into the animal body by artificial or natural means (as when they are produced by bacteria during the progress of disease) form an excess of these combining affinities.

Behring, Ehrlich, and others believe that the antitoxins are neutralized in vitro by the addition of the toxins, in much the same way as an acid is neutralized by an alkali, while Roux, Metschnikoff, Calmette, and other workers do not believe the reaction is so simple, and are of the opinion that the mediation of the living cells of the animal body is necessary to bring about neutralization. It may be possible that the phenomenon is due to ferment action of the antitoxin or some substance produced by the cells of the body when the antitoxins are administered. It seems quite probable that an antitoxin produced by the administration of cultures of bacteria possesses considerable bactericidal action, while a serum obtained by the use of toxin has strong antitoxic properties and weaker bactericidal action.

Diphtheria Antitoxin.—*Antidiphtheritic Serum; Diphtherie-Heilserum,* G.; *Serum antidiphthérique,* Fr.; *Siero Antidifterico,* It.

Definition.—Diphtheria antitoxin is the serum obtained from the blood of animals that have been rendered immune to cultures of diphtheria or the toxic products produced by diphtheria germs by the subcutaneous or intravenous injection of repeated, gradually increasing doses of these substances, and possesses the property, when injected subcutaneously, of conferring immunity to susceptible animals or human beings against infection from diphtheria or curing the disease after it has become established.

History.—As already stated, the discovery of diphtheria antitoxin should be credited to numerous persons working on the subject at about the same time. Convincing proof of the therapeutic importance of diphtheria antitoxin was shown by Roux and Behring in papers presented at the International Congress of Hygiene which met in Budapest in October, 1894. Immediately after this meeting, so conclusive were the results obtained by these observers and so closely did they coincide with the results to be expected from the laboratory experiments that had been made in all parts of the world, that the manufacture of diphtheria antitoxin was undertaken on a large scale in nearly every civilized country.

Preparation.—The preparation of diphtheria antitoxin may be divided into three stages:

1. Toxin.—Cultures are made from the throats of patients suffering from diphtheria by applying to the diseased tissue a pledget of sterilized absorbent cotton, and then rubbing the infected cotton over the surface of coagulated Loeffler's blood-serum, etc., contained in test-tubes of suitable size, which are then placed in the incubator, kept at the body temperature, and allowed to remain for from 12 to 24 hours, at the end of which time examination will show numerous, roundish, pin-point colonies upon the surface. Some of these colonies, if the plants were made from a case of genuine diphtheria, will be found to be pure cultures of the Klebs-Loeffler diphtheria germ. Usually, there will be several varieties of bacteria found upon the surface of the culture-medium, since normally in the mouth and throat there are many different kinds of bacteria

always present. Microscopic examination shows whether the case is one of true diphtheria. A number of colonies are taken from the culture-medium with a sterilized platinum wire, and transferred to fresh tubes of blood-serum. Again the inoculated tubes are placed in the incubator, and allowed to remain until the cultures develop, and are then examined. One or more of the tubes will be found to contain pure cultures of Klebs-Loeffler diphtheria germs. From these pure cultures other tubes are planted, which, after growing 24 hours, serve for inoculating the large flasks of beef bouillon in which the diphtheria toxins are grown, for immunizing the animals that are to produce the antitoxin. Great care should be exercised in planting the flasks, in order that they do not become accidentally contaminated by dust or other means. The planted flasks are then placed in the incubator, and allowed to remain for several days, at the end of which time the clear, transparent bouillon has been changed to a turbid, unsightly looking mixture from the presence of countless millions of diphtheria germs. If microscopic examination shows the presence of only Klebs-Loeffler diphtheria germs, the culture is filtered through unglazed porcelain, which removes all bacteria, and gives the clear, transparent beef bouillon in which are contained the soluble products elaborated by the growing and multiplying germs. The chemical nature of these products has not been satisfactorily determined. For the sake of convenience, this beef bouillon, which contains many other substances besides the toxins, which may or may not be of value in immunizing the animals, is called diphtheria toxin. Before employing the toxin for injection into the animals that are to produce the diphtheria antitoxin, it is necessary to determine the minimum lethal dose for half-grown guinea-pigs which produces death within 4 days. This serves as a basis for the calculation of the quantity needed to immunize larger animals.

2. Immunizing the Animals.—Various animals, such as horses, mules, and donkeys, have been employed for the preparation of diphtheria antitoxin, the former being generally preferred, owing to the ease with which they can be handled, the large quantity of available blood, and the readiness with which they can be immunized against diphtheria. Only young horses, which have been subjected to the Mallein test, and passed a searching physical examination by a veterinarian, should be employed for the production of antitoxin. The individual resistance of horses varies considerably; in some instances very minute amounts of the diphtheria toxin are sufficient to produce alarming symptoms of intoxication and sometimes paralysis. In commencing the treatment, 0.1 Cc. of a toxin of such strength that $\frac{1}{200}$ Cc. will kill test guinea-pigs is quite sufficient for the first injection. The toxins or cultures may be injected subcutaneously or intravenously, the former method being generally preferred; in either case careful aseptic and antiseptic precautions should be observed. Soon after the subcutaneous administration of the toxins the pulse becomes accelerated, the temperature elevated, there is loss of appetite, and more or less swelling occurs at the point of injection—in fact, the symptoms are much the same as those observed in the early stages of diphtheria in human beings. This condition continues for a variable number of hours or days, after which the animal recovers, when a second and larger injection is made, and the same disturbances are noted as after the first dose. Thus the injections are repeated as often as deemed necessary, the quantity being increased in proportion to the resistance of the animal until extremely large amounts of the cultures or toxins can be given without producing alarming symptoms. When the horse has become immune to these doses, the treatment is discontinued for a period of 10 days to 2 weeks, when small amounts of blood are taken for test-purposes by plunging a trocar directly into the jugular vein under antiseptic and aseptic precautions. The blood is set aside and allowed to coagulate, the clot contracts, and the fluid portion of the blood, the serum, which contains the antitoxin in solution, separates as a nearly transparent, straw-colored fluid at the top of the container. This serum, containing the antitoxin in solution, is usually called antitoxin, although it contains various organic and inorganic substances besides. The serum is then tested for its immunizing properties to determine whether the horse is in fit condition to allow a large bleeding to be made for obtaining the antitoxin for commercial purposes. (For the method of testing this serum, see paragraph entitled *Tests.*)

3. Preparation of the Antitoxin.—If the antitoxin from the test-drawing of blood contains a sufficient number of immunizing units per Cc., 5 to 10 liters of blood are drawn, clotting allowed to occur, the antitoxin collected into sterile containers, some preservative, as 0.5 per cent. carbolic acid, 0.4 per cent. trikresol, etc., added, and the fluid set aside for some weeks, during which time more or less precipitate is formed, which

is removed by filtration through sterile filters, tested for strength, asepsis, etc. (see *Tests*), and is finally bottled for the market. The greatest care should be exercised to keep the animals and stables in the best possible condition, and to conduct all operations with the most minute attention to aseptic and antiseptic precautions.

Physical Properties and Tests.—Diphtheria antitoxin is a nearly transparent, straw-colored fluid, which may become slightly turbid on standing from the chemical precipitation of organic or inorganic substances. The serum, as it is obtained from the blood, has a specific gravity of 1.017 to 1.032; average of 10 samples, 1.0262. Total solids, 7.8 to 11.18 per cent.; average of 44 samples, 9.65 per cent. Artificial concentration of the serum, which sometimes is practised surreptitiously, increases the specific gravity and total solids. Various preservatives are generally present, as trikresol (0.4 per cent.), phenol (0.5 per cent.), camphor, etc.

The physiological activity of antitoxin is determined by the number of immunity units contained in each Cc. An immunity unit may be defined as the amount of antitoxin which will neutralize 100 times the minimum fatal dose of a test toxin when the two are mixed together and immediately injected subcutaneously into a standard test guinea-pig (250 Gm. body weight). Several methods have been employed for finding the number of units in a given sample of antitoxin, but most of the serum now appearing on the market is assayed according to Ehrlich's method, which may be briefly stated as follows: A test diphtheria toxin is prepared according to the method already given; and since an antitoxin unit neutralizes the action of 100 times the minimum lethal dose of toxin, the quantity of the test toxin which will exactly neutralize 1 unit of Ehrlich's standard test antitoxin is found by measuring out, with specially graduated pipettes, into several small glass capsules, an amount of Ehrlich's test antitoxin, properly diluted, which contains exactly 1 antitoxic unit, and then adding to each capsule varying quantities of the diphtheria test toxin, and injecting each of the several portions of toxin and antitoxin into a test guinea-pig (250 Gm. body weight). If the toxin is a virulent one, several of the animals will die within 4 days. The smallest quantity of the toxin which neutralizes 1 unit of the antitoxin, and still kills the test animal, is called the L+ dose of toxin, and is employed for assaying any given sample of antitoxin. In determining the strength of a given antitoxin, an L+ dose of toxin is measured out with the special pipette as before into several small glass capsules. To each of these measured portions of toxin are then added various quantities of the diphtheria antitoxin to be tested, the mixture being diluted to 1 Cc. by the addition of a suitable quantity of 0.6 per cent. salt solution. Each portion of the mixture of toxin and antitoxin is injected subcutaneously into a test guinea-pig. One or more of the animals will die within 4 days from the time of the injection. The smallest quantity of serum preventing the death of a test guinea-pig contains 1 antitoxin unit, consequently, if 0.002 of a given sample of serum contains 1 unit, 1 Cc. of the serum will contain 500 units. In testing a given sample of antitoxin as it appears on the market, it will first be necessary to determine the exact quantity of serum in the container, and to divide the entire number of units given on the label by this number, the quotient being the number of units which should be present in each Cc. A comparison of this number of units with the number of units found in each Cc., determined according to Ehrlich's method, will show whether it is up to standard or not.

Several grades of antitoxin appear on the market which differ from each other according to the number of immunity units contained in each Cc. The more concentrated the serum, the greater the cost of production. The poorest grade of serum contains 200 or less units per Cc.; very little of this grade is now sold. The second grade, the product most often employed, contains over 200 units per Cc. The serum is put up sometimes in bottles, preferably in the United States in sealed glass bulbs, each containing a single dose of 500, 1000, 1500, 2000, 3000, or 4000 units.

The injection of small quantities of serum into healthy guinea-pigs, mice, etc., should not produce much local or general disturbance. It should not be possible to obtain aërobic or anaërobic cultures from the serum. Diphtheria and other antitoxins should be kept in a cool dark place. The containers are generally broken by freezing.

The German Pharmacopœia recognizes diphtheria antitoxin both in the fluid and solid form, which are not allowed to be offered for sale or use until they have been examined and sealed at the Royal Institute for Experimental Therapy at Frankfort-on-the-Main. The dry antitoxin is obtained by carefully drying in vacuo high-grade fluid

antitoxic serum, and is free from antiseptic and other preservatives. It occurs in the form of yellow transparent lamellæ or a yellowish-white powder, 1 Gm. of which contains 5000 immunizing units, and is intended for preparing the fluid antitoxin extemporaneously in the original glass-stoppered vials in which it is sold, by addition of the prescribed quantity of sterilized distilled water. It is, however, a fact that dried serum has not proved popular, because of the great difficulty of getting it into solution and the great danger of accidental infection.

Action and Uses.—Diphtheria antitoxin is a specific remedy for the treatment of, or an immunizing agent against, diphtheria. It is usually administered hypodermically, deep injections being made in any part of the body where there is plenty of subcutaneous tissue, as in the abdominal wall or flank. A few reports would indicate that the serum may be followed by satisfactory results when given per stomach or per rectum, but the action is slow and uncertain when given in this way. Opinions vary as to the quantity of antitoxin, or, more properly speaking, the number of immunity units that should be given, some authorities preferring to give several thousands of units at the first injection, repeating them if necessary, while equally good observers claim that just as satisfactory results may be obtained by injecting much smaller quantities and repeating within a few hours if improvement does not quickly follow. Fortunately, unlike most remedies, the exhibition of large doses is not followed by harmful results, as the antitoxin is usually harmless in quantities many times larger than are really necessary to control the disease. Experience proves that the earlier treatment is commenced, the more prompt and certain the cure. In cases in which the disease is merely suspected, antitoxin should be given at once, as it usually does no harm, and may prevent serious developments. For the purpose of preventing the disease in exposed persons, 1000 units are usually sufficient; mild cases treated within 24 hours of the onset of the symptoms require 2000 to 3000 units; in late, severe, or laryngeal cases, 3000 to 4000 or more units may be necessary. In all cases, and whatever the dose, it should be promptly repeated in 6 to 12 hours if improvement does not occur. The age of the patient, contrary to the general rule, need not be considered, except in rare cases, owing to the harmlessness of the remedy. The greater the number of units per Cc., the less is the distention of the tissues at the point of injection, but it is advisable that the specific gravity of the serum should be as nearly as possible that of the serum of the normal body.

Results.—As pointed out by Virchow, "the brute force of figures" is overwhelmingly in favor of the use of diphtheria antitoxin. No remedy has ever become so universally recognized as a specific agent in any disease as has the use of antitoxin in diphtheria. The death-rate in Baltimore (Board of Health report) from diphtheria without antitoxin in 1896 was 51.87 per cent.; in 1898, with the serum, 5.73 per cent. New York, Chicago, and many other American cities show similar reports. The reports from foreign municipalities, hospitals, etc., all proclaim the same verdict. Where 1000 immunity units of antitoxin are injected as a prophylactic after exposure to the disease, almost certain immunity is produced.

Streptococcus Antitoxin.—*Antistreptococcic serum; Streptococcus-Heilserum*, G., *Serum antistreptococcique*, Fr.; *Siero Antistreptococco*, It.—This antitoxin is obtained from the blood of horses that have been immunized against cultures of Streptococcus pyogenes, obtained from cases of erysipelas, puerperal fever, etc. It possesses the same chemical and physical properties as diphtheria antitoxin.

The same tests are applied for determining its purity and sterility. No suitable method has been devised for standardizing it.

Streptococcus antitoxin is employed for the treatment of all infections due to the Streptococcus pyogenes; especially have beneficial results followed its use in erysipelas, puerperal fever, etc. It should be employed in very large doses; 10 Cc. or more every 6 hours should be injected unless the symptoms improve.

Tetanus Antitoxin.—*Antitetanic serum; Tetanus-Heilserum*, G.; *Serum antitetanique*, Fr.; *Siero Antitetanico*, It.—This antitoxin was the first of the antitoxins to be discovered. It is obtained from the blood of horses that have been immunized to the toxins of pure cultures of the tetanus bacillus. The tetanus toxins are the most virulent poisons thus far discovered, consequently great care must be exercised in immunizing the animals.

Tetanus antitoxin has the same physical and chemical properties as diphtheria antitoxin. It is amenable to the same tests for purity and sterility. No method of assay has been generally accepted.

Tetanus antitoxin is of greatest value as a prophylactic administered as soon as possible after infection has taken place, injected in 10 Cc. doses. When employed as a treatment for tetanus, it should be given in extremely large doses, 10 Cc. or more every 6 hours, and continued for a number of days unless the symptoms improve. Sometimes in tetanus the skull is trephined and the antitoxin injected directly into the brain substance in doses of 1 to 3 Cc., but statistics do not show that the serum acts with greater certainty. Since tetanus usually follows infection through a puncture wound, especially in the sole of the foot, it is always best in addition to the serum treatment to enlarge the wound, remove any foreign substances present, and treat it according to the best surgical methods.

Tubercle Antitoxin.—*Antitubercle serum.*—This serum is prepared from the blood of horses immunized to the toxic products of the tubercle bacillus. It has the same chemical and physical properties as the other antitoxins, but appears to be of less value than any of them.

APOCYNACEÆ.—The Dog-bane Family.

Genera about 130, species more than 1000, very abundant in most tropical countries, thence decreasing, rare in temperate regions. So numerous and abundant are these plants in nearly all warm countries, and so generally and intensely poisonous are they, that the following botanical characters should be recognized by everyone: Trees or erect or climbing shrubs, rarely perennial herbs, the juice milky, the leaves almost always opposite and without stipules, the flowers regular, hermaphrodite, the corolla gamopetalous, usually more or less (often very long-) tubular, the stamens 5 (rarely 4) adnate to the corolla at the base, or higher, the anthers usually adherent in a cone-shaped body to the stigma, the pistils superior, variously 2-carpelled, but with a single style, and variously annulate toward the summit, the stigma 2-lobed or cleft, the fruit usually a follicle, and the seed commonly plumose at one or both ends.

In habits, foliage, and inflorescence, these plants are among the handsomest, and many of them among the most fragrant, in the vegetable kingdom, and are largely used for decoration. Otherwise, except for a few edible fruits, and the rubber-yielding species (see Elastica), interest is almost entirely in the medicinal and poisonous properties.

Carissa Carandas L. (*Karonda, Karinda, Karanada, Kalaka*, etc.), of the East Indies, *C. edulis* Vahl (the *Natal plum*), of eastern Africa, *Willughbeia edulis* Roxb., of India, *Hancornia speciosa* Gomez (Manguba), of Brazil, *Carpodium acida* G. Don, of Sierra Leone, *Tabernæmontana dichotoma* Roxb. (the East Indian Apple of Eve), *Melodinus monogynus* Roxb., *Oncinus Cochinchinensis* Lour., and *Plumiera obtusa* L., of India, are the principal edible fruit-yielding species.

Probably no other family possesses alkaloids and glucosides so generally distributed among its members. Active constituents may be encountered in any of the plant-parts, but are especially common and abundant in the barks and seeds. These are very common agents of criminal, military, ordeal, and legal poisoning among savages, and accidental poisoning by them is not infrequent. Very many are utilized as domestic or native remedies, and a number (see Apocynum, Strophanthus, Alstonia, and Acocanthera—under Curare) have been found useful in professional medicine. An enumeration of all those used as medicines or poisons, or known to be actively medicinal or poisonous, would exceed our space-limits, and only the most important will be considered.

Holarrhena antidysenterica Wall. yields the *East Indian Conessi* or *Tellicherry bark* or *Écorcé de Codagapala, Kura, Kurchi, Kuda*, etc. (for an elaborate account see Dymock and Hooper, *Pharm'g'a'. Ind.*, ii. 391), which has very important uses, especially as an antidysenteric (the seeds for headache). The active constituent appears to be the alkaloid *conessine* or *wrightine* ($C_{24}H_{40}N_2$, a yellowish powder, anthelmintic and astringent). The genuine bark, experimented with in Europe, was found to be very active and useful, but fell into disrepute, it is said, because of the common substitution of the nearly inert bark and seeds of *Wrightia tinctoria* Br., which seeds are not bitter and which bark is of a much darker color and not exfoliating in patches, as well as that of *W. tomentosa*, which may be similarly distinguished. The bark of *H. Codago* G. Don and *H. pubescens* Wall., both of India, are very largely used, the seeds as anthelmintics, the roots for toothache, angina, bleeding piles, etc.

Carissa.—Various species are active, apparently due to the presence of glucosides similar to *carissin*, which occurs in *C. ovata stolonifera* F. M. Bailey, of Australia, a powerful heart poison. A similar heart poison, *ouabain*, is yielded by *Acokanthera Schimperi* B. et H. (*C. Schimperi* A. DC.), used as an arrow poison by the Somalis.

Cerbera.—The bark of *C. Tanghinia* Hook. (*Tanghinia Madagascarensis* Pet. Th.) contains the glucoside *tanghinin*, a powerful heart poison. Very similar in activity are the glucosides *cerberid* and *thevetosin*, yielded by *Thevetia Yccotli* DC. (*Gerbera thevetioides* H. et B.), the *Yccotlo* of Mexico. Other species of the genus act similarly and doubtless have similar constituents.

Oleander.—The bark and leaves of the common oleander (*Nerium Oleander* L.), native of southern Europe and adjacent Asia, are actively poisonous. They contain the glucosides *oleandrin* (*pseudocurarin*, very similar to digitalin) and *neriin*.

The root-bark of *N. odoratum* Lam., of the East Indies, called *Kaner*, *Alari*, *Svetapushpa*, etc., acts similarly and contains the highly poisonous glucosides (?) *neriodorin* and *neriodorein* (Greenish, *Pharm. Jour.*, April 23, 1881).

Plumiera.—This genus is rich in native remedies. The bark of *P. lancifolia major* Müll. Arg., of Brazil, containing the glucoside *agoniadin* (contained also in *P. Sucuuba* Spruce), and that of *P. acutifolia* Poir, the *Dolochapo* of India, *Sanbodja* of Japan, or *Ki-tau-hwa* of China, containing *plumierid*, are used in intermittents, etc. The root of the last is also purgative. The milk-juice of *P. retusa* Lam., of Madagascar, is caustic, that of *P. drastica* Mart., the *Tiborna* of Brazil, is a drastic, and that (poisonous) of *P. phagedænica* Mart., the *Sebuii-iiga* of Brazil, is used as an anthelmintic, etc. The bark and root of *P. rubra* L., of the West Indies, and the leaves and bark of *P. Agoniada* Peck., are used as purgatives.

Alkaloids occur in the bark and seed of *Calicarpum albiflorum* T. et B. and of *C. Roxburghii* Don (tetanus-producing), both of India, in the bark of *Ochrosia Ackeringiæ* Miq., *O. coccineus* Miq., *O. elliptica* Lab., and probably in other species of this genus which are used medicinally; in the bark, leaves, and seeds of *Kopsia flavida* Bl., in the leaves and bark of *Hunteria Sundana* Miq., *H. corymbosa* Roxb., *Balberopus villosus* Miq., *Cercocomus macrantha* F. et B., *Conemorpha macrophylla* Don, and *Pseudochrosia glomerata* Bl., all of Java, in various species of *Cyrtosiphonia* and *Vallesia*, the last used as an antiperiodic, *ophioxyline* and *pseudobrucine* in the root of *Ophioxylon serpentinum* W. (*Rauwolfia s.* Benth.), the *Chundra*, *Harkai*, etc., of India, used as an anthelmintic, febrifuge, and oxytocic, the same probably existing also in *O. trifoliatum* Gærtn., of Java, and in *Voacanga fœtida* Thou., of Java. In several species of *Tabernæmontana* occur one or more alkaloids very similar to *buxine*. One of these barks, known as *Johimbehe-bark*, of Camaroons, is used as an aphrodisiac, another in the treatment of elephantiasis. The root-bark of *T. coronana* (L.) W. (*Nerium c.* L.), the *Tagar* or *Nandibattal* of India, and many other species, have more or less important local medicinal uses. The antiperiodic alkaloids *vellosine* (*pereirine*) and *geissospermine* occur in the bark of *Geissosperma Vellozii* Fr. All. (*Tabernæmontana lævis* Vell.), the *Pao Pereiro* of Brazil. The first-named alkaloid exists also in the fruit and leaves.

In the poisonous seeds of *Cerbera Odallam* Gærtn. (*Tanghinia o.*) and in the leaves and bark, as also in those of *C. ladoria* Ham., used as a purgative, occurs the poisonous amaroid *cerberin*.

Arrow poisons are yielded by *Urechites suberecta* Jacq., *Malouetia nitida* Spruce, which acts like curare, and which has caused various cases of accidental poisoning, and by the juice of *Echites venenosa* Mart. (*Caminhoa*), all of tropical America. At least half a dozen other species of *Echites* are used in native medicine. The root of *E. Chilensis* A. DC. is a commercial article in Chile under the name *Quilmey*.

Vinca minor L., *Sinngrün*, contains the principle *vincin*, probably a glucoside, and finds many minor and indefinite uses in domestic medicine.

Fish poisons are yielded by the seeds of *Thevetia Ahouai* DC., and of *T. neriifolia* Juss., both of Brazil, the latter at least containing the glucoside *thevetin*, the bark of *Melodinus Monogynus* Roxb. (*Wrightia piscidia* Don, *Nerium p.* Roxb.), and the leaves and twigs of *Kamettia Malabarica* Kostl., of India.

Unstudied bitter principles exist in the following, leading to their use as antiperiodics or simple bitters: *Cerbera oppositifolia* Lam., of southeastern Asia, the bark of *Continia illustris* Vell. (*Quina de Camanu*), used as a cinchona substitute in Brazil, the wood of *Carissa Xylopicron* Pet. Th., of Bourbon, the barks of *Gonioma Kamassi* E. Mey., used as an angustura substitute at the Cape, and *Alyxia stellata* R. et S., of the East Indies, the latter, as well as probably that of other species of the genus, yielding coumarin.

The following are employed as purgatives: the roots of *Dipladenia pastoreum* A. DC. and *Odontadenia speciosa* Benth., of Brazil, *Echites alexicaca* Mart. (*Purga de Campo*), *E. Cururu* Mart., of Brazil, the root, leaves, and seeds of *Allamanda cathartica* L. (*A. Linnei* Pohl, *A. Aubletii* Pohl, *A. grandiflora* Lam., *Orelia g.*, Aubl.), of tropical America and widely cultivated, *Jahara Sontakha* or *Arasin* of the East Indies, an emetico-cathartic, of special use in lead colic, also other species of *Allamanda*, the fruit of *Pacourea Guyanensis* Aubl., and the milk-juices of various species of *Rauwolfia*, that of *R. canescens* W. vesicant and said to contain an alkaloid.

The following are used as anthelmintics: the milk-juices of *Kickxia Africana* Benth., *Callophora utilis* Mart., of Brazil, the bark of *Echites pubescens* Buch, of the East Indies, also used as an antiperiodic, and the root of *Wrightia Ceylonica* R. Br., the seed of which yields 30 per cent. of oil.

The root and herbage of *Echites longiflora* Desf., the *Flor de Babado* of Brazil, are used for hemorrhoids, the roots of *Ichnocarpus frutescens* R. Br., the *Sarifa*, *Syamalata*, etc., of the East Indies, are used like sarsaparilla, the juice from the bark of *Parameria vulneraria* Radlk., *Tagulaway Balsam* of southeastern Asia, is used as a vulnerary. The entire plant *Wrightia tinctoria* R. Br., the *Kala-Koora* of the East Indies, yields a blue coloring-matter, substituting indigo.

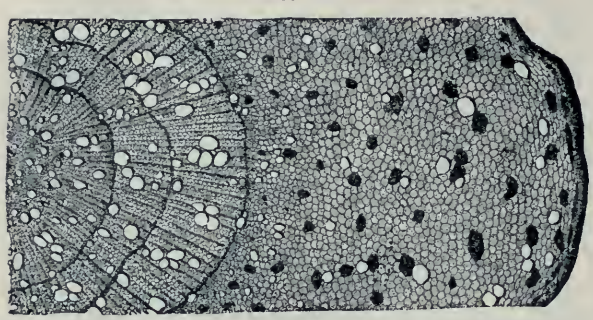
APOCYNUM, *U. S.*

Canadian hemp, *Black Indian hemp* (often called, incorrectly, "Indian Hemp"), E.; *Canadische Hanfwurzel*, G.; *Chanvre du Canada*, Fr.

The dried rhizome and roots of *Apocynum cannabinum* L., or of closely allied species of *Apocynum* (Fam. *Apocynaceæ*).

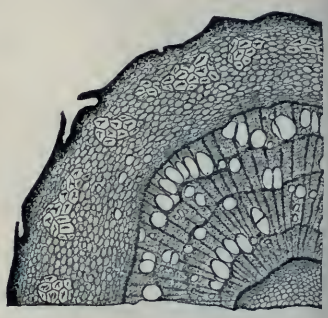
Origin.—We are in complete ignorance as to the species of *Apocynum* which should yield this drug. Up to a very recent period, 5 or more distinct species were included

Fig. 30.



Apocynum cannabinum: transverse section; magnified 25 diameters.

Fig. 31.



Apocynum androsæmifolium: transverse section; magnified 25 diameters.

under the name *A. cannabinum*, even in our standard botanical works, and the plants themselves were not distinguished. It is therefore impossible to ascertain which species yields the different drugs whose actions have been reported upon under that name. This fact doubtless explains, in great part, the conflicting testimony regarding the medicinal activity of the drug. The real *A. cannabinum* is a perennial milky-juiced herb growing throughout the most of North America. The species is probably always glabrous, although present limitations allow of some pubescence on the lower leaf surfaces. The stem is 1 to 2 M. (about 3 to 6 Ft.) high, slender, branched, erect or strongly ascending. The opposite, entire leaves are shortly and stoutly petioled, the blades 5 to 10

Fig. 32.

Apocynum cannabinum (½ Nat.).

Cm. (2 to 4 In.) long and 0.3 to 2.5 Cm. ($\frac{1}{8}$ to 1 In.) broad, ranging from oblong or lance-oblong to broader, just how much broader being as yet uncertain, rounded to narrowed at the base, mucronate at the summit, rather thin and bright-green. A form with broadly ovate, cordate leaves is also referred to this species. A small, dense, and

contracted cyme of greenish-white flowers terminates the stem, the lateral branches quickly surpassing it and producing similar cymes. The flowers are strictly erect, and all those of one cyme mature pretty much at the same time. Their size and structure are determined best from reference to the accompanying illustration. The fruit is a slenderly cylindraceous, tapering, and acute follicle, 15 to 20 Cm. (6 to 8 In.) long, and about 3 or 4 Mm. ($\frac{1}{8}$ to $\frac{1}{6}$ In.) thick. The rhizome is horizontal and somewhat branched, usually more deeply buried than in most other species.

Its nearest relative is *A. album* Greene, with white flowers and relatively narrower leaves. It is readily distinguished by its sprawling. habit, the branches being at their lower portions horizontal or usually deflexed, the terminal portions erect. The plant is perfectly glabrous. It grows in moist and usually sandy soil. The species which most resembles *A. cannabinum*, and which is probably the most common and abundant of the genus, is *A. medium* Greene. The corolla averages about a half larger, is open-campanulate, with the margin somewhat recurved, and white or commonly pinkish. The flowers mature and fall away successively upon the branchlets, and when fully mature they are slightly recurved or sub-pendulous. All the other species at all common in the Northeast have the flowers campanulate like that last described. Southward and westward, *A. pubescens* R. Br., the *Velvety dogbane*, is common. It is readily recognized by its velvety surface throughout. It is not improbable that this species yields the drug that has been so favorably reported upon.

Description.—The following description applies to the drug of commerce, the characters of the different species not having been differentiated.

Of indefinite length, 3 to 8 Mm. ($\frac{1}{8}$ to $\frac{1}{3}$ In.) thick, cylindrical or with a few obscure angles produced by drying, lightly longitudinally wrinkled, and usually more or less transversely fissured; orange-brown, becoming gray-brown upon keeping; fracture weak, brittle, sharply transverse, exhibiting a thin, corky brown layer, the remainder of the bark about as thick as the wood, white or sometimes pinkish, starchy, containing laticiferous ducts, the wood yellowish, of several rings, finely radiate and very coarsely porous, and enclosing a very thin white pith; almost inodorous, the taste starchy, afterward becoming bitter and somewhat acrid.

Constituents.—The active constituents are the bitter glucosides apocynin and apocynein, with which are resin, starch, gum, sugar, a little wax, and tannin. *Apocynin* is amorphous, resin-like, soluble in alcohol and ether, not in water, its activity destroyed by boiling with HCl. *Apocynein* is yellowish, soluble in alcohol and water, not in ether.

Pharmaceutical Preparation.—Fluidextract of Apocynum, U. S. P.

Action and Uses.—In moderate dose apocynum is considered an excellent diuretic. Overdoses produce vomiting and purging, which are due to the gastro-intestinal inflammation which its excessive administration causes. Its employment is said also to promote expectoration and sweating. It stimulates the heart muscle, the vagus nerves, and the vasomotor center, thus slowing the pulse and increasing arterial tension. Its effects are similar to those of digitalis. Because of its diuretic properties, apocynum has been employed in the treatment of cardiac and renal dropsy. Its bitter principle is also said to be tonic and antiperiodic, and for this reason it has been recommended in the treatment of mild cases of malarial fever and in various atonic conditions of the stomach following the acute infectious diseases. It is also said to destroy intestinal worms, but is rarely employed for this purpose at the present time.

The dose of apocynum is from 1 to 5 grains (0.06–0.30 Gm.), but as much as 20 grains (1.3 Gm.) have been employed. An infusion made with $\frac{1}{2}$ ounce (16 Gm.) of the drug in 1 pint (480 Cc.) of water is given in doses of 1 or 2 fluidounces (30–60 Cc.). The dose of the fluidextract is from 1 to 5 minims (0.05–0.30 Cc.); of the tincture, from 5 to 20 minims (0.30–1.30 Cc.), several times daily. *Apocynum adrosæmifolium* has been used for the same purposes, but is practically of no value.

Allied Drugs.—The rhizome of *A. androsæmifolium* L. (*Dog's-bane, Bitter-root, Wild ipecac, Wandering milkweed*) is also used. The plant has a similar range to the other. It is smooth, much lower, and its branches are widely spreading. Its broad and thin leaves, at least the lower ones, are strongly deflexed and its corollas are large, rosy-white, broader than long, and the border strongly recurved. The rhizome is only about half as thick, is tougher, and its bark relatively very much thinner. Its constituents have not been investigated, but it contains glucosides similar to, if not identical with, those of the last.

APOMORPHINÆ HYDROCHLORIDUM, *U. S., Br.*—Apomorphine Hydrochloride.

Apomorphinum hydrochloricum, P. G.—*Chlorhydrate d'apomorphine*, Fr.; *Apomorphinhydrochlorid*, G.; *Chloridrato di apomorfina*, F. It.

Formula, $C_{17}H_{17}NO_2.HCl$. Molecular weight, 301.34.

The hydrochloride of an artificial alkaloid prepared from morphine or codeine.

Preparation.—Morphine and concentrated hydrochloric acid in the ratio of 1 to 20 are introduced into a strong glass tube, securely sealed, and then heated to 140°–150° C. (284°–302° F.) for 3 hours. After cooling, the contents of the tube are diluted with air-free distilled water, supersaturated with sodium bicarbonate, filtered, and the apomorphine extracted with chloroform or ether, from which, upon the addition of hydrochloric acid, the apomorphine hydrochloride may then be obtained in crystalline form. The salt, as well as the alkaloid, should be rapidly dried under a bell jar and protected from moisture and light. Apomorphine may also be prepared from morphine hydrochloride by the process of Mayer (1871), by heating morphine hydrochloride for 1½ to 2 hours to 120° C. (248° F.) with a solution of zinc chloride of such strength that its boiling-point is at 200° C. (392° F.). Matthiessen and Wright, who discovered apomorphine, also obtained it by heating codeine with hydrochloric acid, *chlorocodid*, $C_{13}H_{20}ClNO_2$, being first formed, and which on further heating splits into methyl chloride, CH_3Cl, and apomorphine, $C_{17}H_{17}NO_2$.

Properties.—Apomorphine hydrochloride occurs in minute monoclinic prisms, grayish-white in color, glistening, odorless, having a slightly bitter taste, and acquiring a greenish tint upon exposure to light and air. It is soluble at 25° C. (77° F.) in 39.5 parts (at 15° C. (59° F.) in 40 parts, P. G., in 50 parts, Br.) of water, 38.2 parts of alcohol, 1864 parts of ether, and in 3800 parts of chloroform. The salt decomposes between 200° and 210° C. (392° and 410° F.), and fuses at 263.8° C. (507° F.). The aqueous solution shows a neutral (or very feebly acid, Br.) reaction to litmus-paper. Apomorphine hydrochloride is not colored when treated with sulphuric acid; with nitric acid a deep purple color fading to orange is produced; with sulphuric acid containing a trace of selenious acid, a dark blue color, fading to violet, and then turning black; with sulphuric acid containing a trace of nitric acid, a blood-red color, fading to orange; with sulphuric acid containing a trace of ferric chloride, a pale-blue color; with sulphuric acid containing a trace of ammonium vanadate, a violet-blue color, changing to deep greenish blue; with sulphuric acid containing a little paraldehyde, a green color, fading to reddish brown; with sulphuric acid containing potassium iodate, a black color, changing to brown, and finally to pale brown. If sulphuric acid be added to a crystal of apomorphine hydrochloride and a crystal of potassium nitrate, the latter is colored red, and on stirring with a glass rod the solution becomes green, then blue, then purple, and finally cherry red. Acetic acid dissolves the salt without color, but on adding a trace of potassium iodate, the solution turns blood red, changes to purple, and on adding a little ether and shaking, the latter assumes a blue color (U. S.). Apomorphine is slowly decomposed in boiling water or boiling alcohol. With nitric acid a blood-red color results. With solution of sodium or potassium hydroxide a purple color develops upon exposure to air, gradually changing to black. Dissolved in ammonium hydroxide solution a purple color develops. Sodium bicarbonate added to an aqueous solution throws down an amorphous precipitate of apomorphine, which rapidly turns green and forms a bluish-green solution with alcohol, a purple one with ether or benzene, and a violet-blue one with chloroform.

Tests.—Gold chloride test-solution produces a reddish-purple precipitate in a solution of apomorphine hydrochloride. Diluted ferric chloride test-solution colors a solution of the salt red (distinction from morphine, which, under the same test, is colored blue). If the salt imparts at once an emerald-green color to 100 parts of water on being shaken with it a few times in a test-tube, it should be rejected.

Silver nitrate test-solution added to the aqueous solution of the salt throws down a white precipitate, insoluble in nitric acid, soon turning black by reduction to metallic silver, and instantly reduced by addition of ammonia-water. If 0.05 Gm. be shaken with a solution made by dissolving 0.05 Gm. of ferrous sulphate in 10 Cc. of water, the solution will gradually turn blue and then black; on the addition of some alcohol, the solution resumes its blue color (absence of codeine, morphine, narceine, and narcotine). —U. S.

Apomorphine hydrochloride should be kept in small non-actinic glass vials. It is always dispensed in the form of aqueous solutions, and amber-colored vials should be used for the same; the gradual green coloration of the solution can be prevented by addition of a few drops of hydrochloric or acetic acid.

Action and Uses.—Either because of some idiosyncrasy of the individual or because of the employment of an impure article, a number of untoward symptoms have followed the administration of moderate doses of apomorphine. Nervous irritation, hyperæsthesia, depression of the circulation, shallow, irregular respiration, convulsions, and collapse have been noted.

In moderate amounts apomorphine stimulates the motor centers of the brain and increases the force and rapidity of the pulse by stimulating the accelerator nerves of the heart and the vasomotor center. Poisonous amounts depress the circulation and produce tetanic convulsions which are probably of spinal origin. The motor and sensory nerves and muscles also are depressed by overdoses of this drug. It has little or no effect upon respiration unless given in poisonous doses, when it causes the breathing to become rapid and irregular. Apomorphine increases the secretion of mucous membranes and stimulates the vomiting center in the medulla, thereby causing emesis.

Apomorphine is employed as a sedative expectorant in the treatment of acute bronchitis, when the air-passages are inflamed and the secretion scanty. It is probably the most useful emetic which we have, and may be employed as such in the treatment of narcotic poisoning, in chronic catarrh of the stomach and air-passages, and in dislodging foreign bodies from the bronchi or œsophagus. It has also been used with success in treating spasmodic asthma and spasmodic croup. Choreic movements and hiccough are also said to have been relieved by its administration. Apomorphine has been used in small non-emetic doses as a valuable nervous sedative in delirium tremens.

As an expectorant, apomorphine is given by the mouth in doses of from $\frac{1}{40}$ to $\frac{1}{25}$ of a grain (0.0015–0.0025 Gm.). As an emetic, $\frac{1}{20}$ of a grain (0.003 Gm.) is usually sufficient, but as much as $\frac{1}{5}$ of a grain (0.01 Gm.) may be given to very robust patients. The last amount should be given with care, however, as it may occasion great depression or collapse.

AQUA, *U. S.*—Water.

Eau, Fr.; *Wasser*, G.; *Agua*, Sp.; *Acqua*, It.

Potable water in its purest attainable state (U. S.). Aqua was dropped from the last Br. P.

Formula, H_2O. Molecular weight, 17.88.

Properties.—Water is often combined in nature, as in many crystalline compounds, and is very abundant in the free state. Natural water is an excellent solvent for most gases and many salts, but it is rarely found pure; B. M. Brackenridge and E. Stieren observed (1860) chemically pure water in the spring of a ravine known as "the Dark Hollow," in Allegheny County, Pa. With few exceptions, *spring water* contains carbon dioxide in solution, and by its agency dissolves calcium carbonate and sulphate and magnesium carbonate from the soil. Such water precipitates an insoluble lime-soap from solution of ordinary soap, and is called *hard*. Hardness is of two kinds, *temporary* and *permanent*. The temporary hardness is due to dissolved carbonates of calcium and magnesium, which are precipitated on boiling the water, by which the solvent carbon dioxide is driven out and the water is thus made soft to a great extent. The permanent hardness is due to magnesium and calcium sulphates, which cannot be removed by boiling. Clark's method for removing hardness from waters consists in adding lime water in sufficient quantity to the water, by which the bicarbonates of calcium and magnesium are converted into insoluble carbonates and precipitated. Hardness is expressed in degrees: 1 degree represents 7 parts of calcium oxide (German) or calcium carbonate (French) in 100,000 parts of water.

A precipitation takes place in rivers, from the water of which, owing to its extended surface, the carbon dioxide is mostly given off; hence *river water* is usually soft. Both spring and river waters contain variable quantities of salts of alkalies in solution, of which they cannot be deprived except by distillation.

Rain water and *snow water* are free from such saline compounds, except the portions falling first; these contain particles of dust and various organic and inorganic matters which had been suspended or dissolved in the air. Among them, ammonia, iodine, chlorine, and

nitric acid have been found, the latter more particularly during a thunder-storm, the former two elements occasionally, while ammonia or allied compounds are always present in inhabited regions. It is advisable, therefore, to collect rain water only some time after the rain has commenced falling, and as far removed from dwellings as possible; it will then contain a little carbon dioxide, which has been dissolved from the air.

The purity of running and well-water is affected by the nature of the surrounding soil and the proximity of decaying animal or vegetable matter, the decomposition-products of which may find an outlet into the former by natural drainage, sometimes from a considerable distance, and render such water unwholesome and unfit for many purposes. The refreshing taste of spring water is mainly due to the carbon dioxide dissolved therein. Of secondary importance is the small quantity of saline compounds contained in it. When the latter is permanently increased beyond a certain quantity, the spring is called a *mineral spring* (see AQUÆ MINERALES).

Most spring waters are unfit for chemical and pharmaceutical uses, but may often become adapted therefor after boiling and filtering. River water, if not naturally bright and transparent, is improved by filtration through sand and charcoal, and may then be employed if nearly free from organic matter, the amount of which may be approximately ascertained by a dilute solution of potassium permanganate, which will permanently impart its color to the water as soon as the organic matter and other deoxidizing agents accidentally present have been destroyed or oxidized. But distilled water is best for all the purposes indicated. Its taste is insipid, owing to the absence of carbon dioxide or to the minute quantity of this gas absorbed by contact with air.

Water may often be purified sufficiently for manufacturing purposes by treating it with alum, 2 grains to a gallon; and letting it stand 48 hours or longer, until the impurities settle. Gelatinous aluminum hydroxide gradually forms, which carries down mechanically as well as by occlusion most of the impurities present.

Pure water in contact with untarnished surfaces of lead becomes contaminated; the dissolved oxygen and carbon dioxide in the water convert the lead into carbonate, which goes into solution. Such water may give rise to lead-poisoning. Pure water or soft waters are more apt to be contaminated than hard waters, as the salts in the latter soon give rise to a protective film over the surface of lead.

There is little danger of lead-poisoning in the use of lead pipes and connections in water-supplies to houses, as the pipes soon become coated with an insoluble film. Water that has been standing for some time in hydrant pipes should be allowed to run off before using the water for drinking.

When water has been contaminated by organic matter, especially animal, it is dangerous for drinking-purposes. Such water responds strongly to tests for ammonia both free and "albuminoid," and for nitrites and nitrates which result from oxidation of the ammonia. Ammonia is determined by means of the exceedingly delicate Nessler's Solution (double potassium-mercuric iodide in strong solution of caustic potash).

Free ammonia should not exceed 0.08 part per million of water, and albuminoid ammonia not more than 0.15 part per million, otherwise the water should be regarded with suspicion for drinking-purposes. The presence of undue amounts of nitrite and nitrate and chlorine points to contamination with animal matter, as urine or sewage.

The reader is referred to special works on water analysis for discussions as to what constitutes a good drinking-water, how the constituents are determined quantitatively, and how they are to be judged. Descriptions of methods for purifying water for large cities, etc., by filtration and chemical treatment may be found in comprehensive works on chemistry or technology.

It has been found by experiments that water has a corrosive action on lead when it contains free acid or alkalies, oxygen, nitrates, chlorides, and sulphates. This corrosive effect is neutralized by such compounds as calcium carbonate, sodium bicarbonate, ammonium carbonate, calcium silicate, silica, and soluble phosphates.

At the temperature of 0° C. (32° F.) water freezes, forming transparent crystals of ice; if entirely undisturbed, it may be cooled to several degrees below this point without freezing, and if now slightly agitated it will at once congeal, the temperature rising to the freezing-point in consequence of the liberation of latent heat. Water impregnated with salts, particularly such as are readily soluble in it, freezes at a lower temperature, the ice being free from the compounds which were dissolved in the water. Hence, water equal in purity to distilled water may be obtained by melting perfectly clear and transparent

ice under conditions which preclude the admixture of dust and other impurities. *Sea water*, which has the specific gravity 1.027 and contains about 3½ per cent. of salts, yields ice of as great purity as river water.

The boiling-point of water is 100° C. (212° F.) at normal barometric pressure (760 Mm.), and rises beyond this temperature if notable quantities of salts, etc., are dissolved in it or if the pressure is increased; on the reduction of pressure water boils at a lower temperature.

The density of distilled water at 15° C. (59° F.) or at 15.5° C. (60° F.) is by general consent regarded as the unit by which the density of liquid and solid bodies is measured. In Europe, however, this unit is sometimes taken from water at its greatest density, and several of the tables published in the U. S. Pharmacopœia (1880) are based upon this unit. The specific gravity of water decreases with the rise of temperature, and increases gradually as the temperature is lowered until 4° C. (39° F.) is reached, when it has its maximum density, becomes lighter again toward the freezing-point, and expands very considerably when passing into the solid state, ice having the specific gravity 0.916. When converted into vapor at 100° C. (212° F.), water expands to nearly seventeen hundred times in bulk, and forms a transparent and colorless gas having the specific gravity 0.455; it has therefore less than one-half the density of atmospheric air. When mixed with air, it condenses into minute drops, to which the opaqueness of steam is due; the oversaturation of air with aqueous vapor causes a similar condensation in the atmosphere, hence the appearance of clouds.

Tests of Purity.—A colorless, limpid liquid, without odor or taste at ordinary temperatures, and odorless when heated. Water should be perfectly neutral to litmus-paper, and 10 Cc. contained in a test-tube of about 40 Cc. capacity, when acidulated with 1 Cc. of diluted hydrochloric acid and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by addition of an equal volume of freshly prepared hydrogen sulphide test-solution after standing, well stoppered, in a warm place—35° C. (95° F.)—for at least half an hour, nor should the further addition of ammonia-water to this solution cause a coloration or turbidity therein (showing the absence of heavy metals). On evaporating 1000 Cc. of water on a bath of boiling water, it should not leave a residue weighing more than 0.5 Gm. (limit of soluble salts), and this residue, when ignited, should not carbonize nor evolve ammoniacal or acid vapors. If 200 Cc. of water be acidulated with hydrochloric acid and heated to boiling, and 0.5 Cc. of barium chloride test-solution added, the liquid, when cooled and filtered, should give no further precipitate on the addition of a few drops of barium chloride test-solution, even on standing (limit of sulphates). If 200 Cc. of water be acidulated with nitric acid and heated to boiling, and 0.5 Cc. of tenth-normal silver nitrate solution added, the liquid, when cooled and filtered, should not be affected by the subsequent addition of a few drops of silver nitrate test-solution (limit of chlorides). If 10 Cc. of water mixed with a few drops of diphenylamine test-solution be carefully poured upon about 3 Cc. of sulphuric acid free from nitrous compounds, contained in a test-tube, so as to form a separate layer, no blue color should be formed at the line of contact of the two liquids (limit of nitrates). If to 50 Cc. of water contained in a glass cylinder 2 Cc. each of sulphanilic acid test-solution and naphthylamine acetate test-solution are added, and the solution well mixed, no distinct pink coloration should appear within 5 minutes, when viewed from above and placed upon a white surface (limit of nitrites). If to 50 Cc. of water contained in a glass cylinder 2 Cc. of alkaline mercuric potassium iodide test-solution (Nessler's solution) be added and thoroughly mixed, no yellow or brownish tint should be produced immediately; the cylinder should be viewed from above and placed upon a white surface. On heating to boiling, 100 Cc. of water, acidulated with 10 Cc. of diluted sulphuric acid, and subsequently adding 0.5 Cc. of tenth-normal potassium permanganate solution, the color of the liquid should not be completely destroyed after it has been boiled for 10 minutes (limit of organic or other oxidizable substances).—U. S.

Action and Uses.—From a medicinal point of view, water is used internally in large quantities for the purpose not only of allaying thirst, but of increasing the ability of the kidneys to eliminate impurities from the body. While it cannot be truly said to possess medicinal properties, it is nevertheless a fact that the drinking of pure water exercises a distinct medicinal influence in gouty, rheumatic, and other affections depending upon perverted metabolism.

Used externally water is chiefly employed for the purpose of bathing, and in most instances where baths are employed for medicinal purposes the water is more or less strongly impregnated with mineral substances (see AQUÆ MINERALES).

Pure water, at varying temperatures, is constantly employed in medicine for the purpose of soothing irritation of the peripheral nerves, modifying the condition of the general circulatory system, and increasing the excretive activity of the skin.

Used externally at temperatures varying from that of the body to 70° or even 65° F., water is employed for the purpose of relieving fever and the nervous irritation often associated with this symptom of disease.

There is not space in this volume to discuss thoroughly the subject of hydrotherapy, and the reader must refer to special works for directions as to the various means by which water at different temperatures can be employed as a powerful and valuable remedial agent (see Baruch's *Hydrotherapy*). Much depends upon the manner of its employment. Perhaps the most noteworthy use of water in the bath is in the so-called Brand treatment of typhoid fever, which consists in immersing the patient in a tub of water at about 65° to 70° F., rubbing his body actively while he is in the water, with the object of not only reducing his temperature, but, more important, of increasing the elimination of toxic materials from his body by the skin and kidneys, equalizing the circulation, thereby overcoming conditions of stasis and anæmia in various portions of the body, and in addition stimulating the nervous system so that it is not overwhelmed by the toxæmia of the disease.

AQUA AMMONIÆ, *U. S.*—Ammonia Water.

Liquor ammoniæ, Br.; *Liquor ammonii caustici*, P. G.; *Spiritus salis ammoniaci causticus, Ammonia aqua soluta.—Ammoniaque liquide, Eau (Solution, Liqueur) d'ammoniaque*, Fr.; *Salmiakgeist, Aetzammoniak, Ammoniak-Flüssigkeit*, G.; *Ammoniaca*, F. It.; *Amoniaco liquido*, Sp.

An aqueous solution of ammonia containing 10 per cent. by weight of gaseous ammonia.—U. S.

Formula of ammonia gas, NH_3. Molecular weight, 16.93.

Origin.—Ammonia is produced during the putrefaction of all organisms and of many organic compounds containing nitrogen; it exists in the air and in the soil, mostly in combination with acids in the air, as carbonate and nitrite. Ammoniacal salts are met with in most plants and animals. The products of the dry distillation of many nitrogenated compounds contain ammonia, and it is from such a source—namely, from the so-called gas-liquor, a by-product of the manufacture of illuminating-gas—that ammoniacal salts are principally obtained (see Ammonii Chloridum and Ammonii Sulphas).

Preparation.—AMMONIA WATER. The U. S. Pharmacopœia of 1900, like its predecessor, not stating an official method for preparing ammonia water, the method of 1870 is here given; it will be found to yield an excellent product on a small scale: Take of ammonium chloride in small pieces, lime, each, 12 troy ounces; water, 6 pints; distilled water a sufficient quantity. Pour a pint of the water upon the lime in a convenient vessel, and after it has slaked stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the water and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort of the capacity of 16 pints, and add the ammonium chloride. Place the retort on a sand-bath, adapt to it an empty wash-bottle, and connect the latter with a 2-pint bottle containing a pint of distilled water, by a glass tube reaching nearly to the bottom. Surround the last-named bottle with ice-cold water and apply heat to the sand-bath, gradually increasing it until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient distilled water to raise its specific gravity to 0.960. Lastly, keep the liquid in small bottles, well stopped.

According to the British Pharmacopœia, 1 pint of strong solution of ammonia is mixed with 2 pints of distilled water.

When ammonium salts are treated with the hydroxide of a metal of the alkalies or alkaline earths, the corresponding salts of the metals are formed and ammonia and water are set free; thus, $2NH_4Cl + Ca(OH)_2$ yields $CaCl_2 + 2NH_3 + 2H_2O$. It is important to heat the mixture gradually, so that much of the gas may be given off before the boiling temperature is reached. A rapid heating is apt to cause the extrication of the gas with such violence that the contents of the retort will boil over. In preparing

ammonia on the large scale, it is advantageous to connect the wash-bottle with a series of stoneware receivers shaped like Woulf's bottles, so that the gas which is not absorbed in the first will pass into the second receiver, and so on.

The employment of a considerable excess of calcium hydroxide has been found advantageous to insure the complete decomposition of the ammonium salt. On account of this excess the residue in the retort will contain a basic calcium chloride having the composition $CaCl_2 3CaO$, which, after having been filtered from the lime, may be neutralized by hydrochloric acid and evaporated to dryness, to be utilized as calcium chloride.

On the large scale ammonia water is usually made with common water, the natural impurities of which it contains, together, frequently, with notable quantities of iron derived from the iron delivery-tubes employed. Chemically pure ammonia water may be obtained from this by heating it, or, preferably, the commercial stronger ammonia water, in a glass flask or retort, and conducting the gas, a considerable amount of which is evolved below the boiling-point of water, by means of glass tubes, into distilled water.

Gaseous ammonia is obtained by passing the gaseous products in the above processes over dry caustic potash or calcium chloride.

Properties.—Gaseous Ammonia.—Ammonia is a colorless gas having a strong, penetrating odor and an acrid, alkaline taste. In pure oxygen it burns, forming water and free nitrogen. It has the specific gravity 0.593. By a pressure of 7 atmospheres at 15° C. (59° F.), or when cooled to —40° C. (—40° F.) at the ordinary atmospheric pressure, it condenses into a colorless liquid much lighter than water, which boils a few degrees above this temperature and crystallizes when placed in a mixture of solid carbon dioxide and ether at about —75° C. (—103° F.). Water dissolves about 727 times its volume of ammonia gas at 15° C. (59° F.).

Liquid ammonia is sold in iron cylinders, and is extensively used in the manufacture of ice; liquid ammonia in evaporating produces a low temperature, by which water is made to freeze. Over five million pounds of liquid ammonia are manufactured in the United States annually, of which The National Ammonia Company, of St. Louis, Mo., produces more than 75 per cent.

Ammonia gas unites with acids directly to form salts which resemble the alkali salts in all respects. It is highly probable that in these salts there is a group of atoms (NH_4) which has received the name "Ammonium," and corresponds to the metals potassium, sodium, etc. Thus, $NH_3 + HCl = (NH_4)Cl$. The nitrogen changes apparently from the trivalent state in NH_3 to the pentavalent state in $(NH_4)Cl$. The group (NH_4) cannot be obtained free; it exists only in the salts. It is believed that when ammonia gas is passed into water a hydroxide of ammonium is formed—thus, $NH_3 + H_2O = NH_4OH$—corresponding to KOH or NaOH. This is easily broken down into NH_3 and water.

Ammonia-water.—The official solution of ammonia constitutes a colorless, transparent liquid possessing the odor and taste of the gas, being lighter and having a lower freezing-point than distilled water. It has a specific gravity of 0.958 at 25° C. (77° F.), 0.959, Br., 0.960, P. G., at 15° C. (59° F.), and imparts a brown color to turmeric paper, a blue color to litmus-paper, and a green color to the juice of violet-flowers. It evolves dense white fumes when a glass rod moistened with hydrochloric or acetic acid is held over the liquid. Sometimes commercial ammonia-water, when carelessly prepared, shows a rose tint when acidified, especially by nitric acid, due to such impurities as pyrrol, aniline, naphthalene, and pyridine, which are derived from the gas-liquor. Ammonia neutralizes all acids, forming salts which are mostly colorless and crystallizable, possess a sharp, saline taste, and when heated to redness are entirely volatilized without residue, unless the acid be non-volatile; even the solutions of most ammonium salts, when evaporated or heated to boiling, lose a portion of the ammonia.

Tests.—Ammonia-water should evaporate at the temperature of boiling water without residue (salts). On slightly supersaturating 10 Cc. of ammonia-water with diluted sulphuric acid, no empyreumatic odor or red color should be developed, and if to this liquid 1 Cc. of centinormal potassium permanganate solution be added, the pink color should not be completely destroyed within 10 minutes (absence of readily oxidizable matters). If ammonia-water be mixed with four times its volume of lime-water, it should not afford an immediate turbidity (only minute traces of carbon dioxide); and if it be diluted with twice its volume of water, it should not be affected by ammonium oxalate test-solution (absence of calcium), nor should it be affected by hydrogen sulphide test-

solution either before or after neutralization with hydrochloric acid (absence of metallic impurities). If ammonia-water be slightly supersaturated with nitric acid, it should not be affected by barium chloride test-solution (absence of sulphates), nor by silver nitrate test-solution (chloride); and if a third portion of the acidulated liquid be evaporated on a water-bath to dryness, it should afford a colorless residue, which, on ignition, should be completely volatilized (absence of coal-tar bases and of fixed impurities). If 10 Gm. (10.42 Cc.) of ammonia-water be diluted with distilled water to measure 100 Cc., then 34 Cc. of this solution should require for neutralization not less than 20 Cc. of normal sulphuric acid, litmus being used as indicator (each Cc. corresponding to 0.5 per cent. of ammonia).—U. S. The Br. P. requires for each Gm. of ammonia-water 5.9 Cc. of volumetric sulphuric acid, and the P. G. for 5 Cc. of ammonia-water 28 to 28.2 of normal hydrochloric acid.

The solutions of ammonium salts yield orange-colored crystalline precipitates with platinum chloride and sodium cobaltic nitrite, and, if not too dilute, white ones with tartaric acid or acid sodium tartrate. The most delicate tests for ammonia are those of Einbrodt (1852) and of Nessler (1856). *Einbrodt's reagent* is an aqueous solution of mercuric chloride rendered slightly alkaline by the addition of a minute quantity of potassium carbonate. The test is applied to an alkaline solution, or if the solution has an acid reaction, it should be rendered faintly alkaline by the addition of potassium or sodium hydroxide, when the test-liquid will produce a white cloudiness if only $\frac{1}{5000000}$ of ammonium is contained in the solution.

Nessler's reagent is a solution of potassium-mercuric iodide, made either by saturating a solution of potassium iodide with mercuric iodide, and rendering this alkaline by potassium hydroxide, or it is prepared from potassium iodide and mercuric chloride (see Hydrargyri Iodidum Rubrum). With solutions of ammonia or ammoniacal salts it gives a brown-red precipitate, or if very dilute an orange color. It may be used for the quantitative determination of minute quantities of ammonia by diluting the liquid until with Nessler's Solution only an orange tint is produced, which is compared with that obtained from a solution of ammonium chloride of known strength by diluting the latter until the same coloration is produced with the test-liquid.

Action and Uses.—Ammonia water is used chiefly for its cleansing properties when added to ordinary water. It is very rarely used medicinally (see below).

AQUA AMMONIÆ FORTIOR, *U. S.*—Stronger Water of Ammonia.

Liquor ammoniæ fortis, Br.; *Strong solution of ammonia*, E.; *Eau d'ammoniaque forte*, Fr.; *Starker Salmiakgeist*, G.

This solution differs from ordinary ammonia water chiefly in the proportion of ammonia gas held in solution, and contains 28 per cent. (U. S.) or 32.5 (Br.) by weight of the gas. It has the specific gravity 0.897 at 25° C. (77° F.) (U. S.) or 0.891 (Br.), and is prepared on a large scale by distilling ammonium chloride or sulphate, obtained from gas-liquor, with milk of lime, purifying the gas by passing it over quicklime, and passing the gas into a series of vessels filled about three-fourths with water until saturation is reached.

Stronger ammonia water is a colorless, transparent liquid, with an excessively pungent odor, very acrid, alkaline taste, and a strongly alkaline reaction. If it be diluted with twice its volume of water, it should respond to the reactions and tests named under Ammonia Water. 23 Cc. of normal sulphuric acid should be required to neutralize 1.7 Gm. of stronger ammonia water (U. S.) or 19.1 Cc. of normal acid for 1 Gm. (Br.), rosolic acid being used as indicator.

Great care should be taken in opening bottles containing stronger ammonia water, lest the vapor of ammonia frequently collected in the upper part of the bottle should blow out the stopper and cause injury to the eyes or mucous membranes of the nose and throat by inhalation.

Action and Uses.—The medicinal properties of ammonia as an internal remedy will be discussed under Spiritus Ammoniæ Aromaticus. The stronger ammonia-water is never employed in internal medicine. The 10 per cent. preparation may be given internally or injected intravenously when a powerful and rapidly acting circulatory stimulant is required, but in either case it should be largely diluted. When applied to the skin in concentrated form ammonia causes reddening of the tissue followed by burn-

ing pain, and if the contact be sufficiently long an escharotic action is obtained. Weaker solutions act as rubefacients and are frequently employed in the preparation of stimulating liniments. When an escharotic action follows its use, the ulcer resulting is painful and very slow to heal. When employed intravenously ½ drachm (2 Cc.) should be diluted with 1 ounce (30 Cc.) of water, and very slowly injected into a vein of the leg. If given in too concentrated a form, it may produce immediate cardiac arrest. Abscesses almost invariably result from its hypodermic use, and for this reason it should not, as a rule, be so used. As a vesicating agent, a few drops may be placed near the painful area and covered with a watch crystal. The time required for producing a blister rarely exceeds ten or fifteen minutes when the stronger water is used, but somewhat longer when the 10 per cent. preparation is employed. Poisoning from the inhalation of ammonia gas or the drinking of either of the ammonia waters is not an uncommon occurrence. If a sufficient amount of the gas be inhaled, death may take place rapidly, resulting from spasm or œdema of the glottis; the same occurrence may also result from drinking the ammoniacal water. Inhalation of moderate amounts causes severe bronchitis and at times œdema of the glottis and lungs. The buccal and nasal mucous membranes are also irritated and at times partially destroyed. When taken internally, if death is not immediate, the symptoms of severe gastro-enteritis ensue. Violent abdominal pain and spasm, accompanied by either delirium or stupor, passing into collapse, coma and death result. This condition is met by the prompt administration of vegetable acids, such as vinegar and lemon juice, demulcents and opium for the relief of pain, and supporting treatment as the symptoms require.

As a vesicant, ammonia water may be used in the various conditions in which blistering is beneficial, as in obstinate neuralgias, inflamed joints, and in suppression of urine. As a stimulating lotion, it may be used when diluted in various rheumatic, gouty, neuralgic, and spasmodic conditions. It can be applied also with benefit when diluted to the spot stung by insects, such as bees, spiders, and mosquitoes.

The internal dose of the 10 per cent. preparation is from 10 to 30 minims (0.6–2 Cc.), largely diluted with water.

AQUA AMYGDALÆ AMARÆ, *U. S.*—Bitter-almond Water.

Aqua amygdalarum amararum, P. G.—*Eau d'amandes amères*, Fr.; *Bittermandelwasser*, G.; *Acqua distillata di mandorle amare*, F. It.

Preparation.—Oil of bitter almonds, 1 Cc.; distilled water, 999 Cc. Dissolve the oil in the distilled water by agitation and filter through a well-wetted filter.—U. S. (16 minims of oil of bitter almonds, dissolved in 33¼ fluidounces of distilled water, will yield a preparation of the same strength.)

Made by this process, bitter-almond water is a very unreliable preparation, owing to the variable amount of hydrocyanic acid contained in the oil of bitter almonds, and if the latter has been deprived of its hydrocyanic acid, the bitter-almond water prepared from it will possess no virtue except for imparting flavor.

Bruise bitter almonds 12 parts, and express as much fixed oil as possible without the aid of heat. Powder the press-cake, mix it thoroughly with water 20 parts, and distil off 9 parts into a receiver containing alcohol 3 parts, determine the amount of hydrocyanic acid in the distillate, and then dilute with a mixture of alcohol 1 part and distilled water 3 parts, so that 1000 parts of the mixture contain 1 part of hydrocyanic acid. Thus prepared, bitter-almond water is nearly clear, and has a strong odor of hydrocyanic acid and oil of bitter almonds, the latter remaining after the hydrocyanic acid has been removed by means of silver nitrate.—P. G.

In making bitter-almond water by the latter process the fixed oil is removed, because it hinders the reaction between the amygdalin and emulsin, to complete which maceration of the expressed almonds with water for about 10 or 12 hours is advisable at a temperature of about 30° or 35° C. (86° or 95° F.). The almond mixture is then placed upon a perforated diaphragm and heat applied to the still.

When the requisite quantity of water has distilled over, 27 Gm. of the distillate are diluted with 54 Gm. of distilled water, mixed with sufficient magnesia, previously rubbed with water to render it milky, and with a few drops of solution of potassium chromate; decinormal (volumetric) solution of silver nitrate is then added until the red color produced by the latter ceases to disappear on stirring; each Cc. of the silver solu-

tion represents 0.01 per cent. of HCN. A bitter-almond water containing 0.1 per cent. of hydrocyanic acid will require 10 Cc. of the silver solution. The strength may also be determined gravimetrically by adding to 1000 grains of the water first a little ammonia, then a slight excess of nitric acid, and finally solution of silver nitrate until a precipitate ceases to appear; this, when washed and dried, should weigh exactly 5 grains.

Action and Uses.—Bitter-almond water is a preparation which cannot be highly recommended. Any medicinal properties which it possesses depend upon the hydrocyanic acid which it contains, and this varies greatly in quantity.

The dose of bitter-almond water is 3 to 4 teaspoonfuls (12–16 Cc.).

AQUA ANETHI, *Br.*—Dill Water.

Eau d'aneth, Fr.; *Dillwasser*, G.

Preparation.—Take of dill fruit bruised, 1 pound (or 500 Gm.); water, 2 gallons (or 10 liters); distil one-half.—Br.

The water, which is at first slightly milky if prepared by this process, possesses the odor and taste of dill fruit.

Action and Uses.—Dill water is sometimes given to nursing mothers with the idea that the drug will be eliminated in the milk and so relieve infantile colic. It has no special advantages over other official waters which are used as vehicles, and is very rarely employed.

AQUA ANISI, *U. S., Br.*—Anise Water.

Eau d'anis, Fr.; *Aniswasser*, G.; *Acqua distillata di anice*, F. It.

Preparation.—Oil of anise, 2 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the oil with the purified talc, add the water gradually with continued trituration; filter, and pass the filtrate through the filter repeatedly until the anise-water is perfectly clear.—U. S.

(32 minims of oil of anise may be triturated with 240 grains of purified talc, and will require 2 pints of distilled water.)

Anise-fruit bruised, 1 pound (or 500 Gm.); water, 2 gallons (or 10 liters). Distil one-half.—Br. Distilled from the fruit, anise water has a more pleasant odor and taste than that made from the oil.

Action and Uses.—Anise water is a useful vehicle for medicines which are intended to expel flatus from the gastro-intestinal tract, and is sometimes added to laxative mixtures to prevent griping.

AQUA AURANTII FLORUM, *U. S.*—Orange-flower Water.

Aqua Aurantii floris, Br.; *Aqua florum naphæ.—Eau (Hydrolat) de fleur d'oranger, Eau de naphe*, Fr.; *Orangenblüthenwasser*, G.; *Acqua distillata di arancio*, F. It.; *Agua de azahar*, Sp.

Preparation.—Stronger orange-flower water, distilled water, of each, 1 volume. Mix them immediately before use.—U. S. It is used as a vehicle.

The British Pharmacopœia directs that the distilled orange-flower water of commerce shall be mixed with twice its volume of distilled water immediately before use.

AQUA AURANTII FLORUM FORTIOR, *U. S.*—Stronger Orange-flower Water; Triple Orange-flower Water.

Water saturated with the volatile oil of fresh orange-flowers, obtained as a by-product in the distillation of the oil of orange-flowers. It should be kept in bottles loosely stoppered with a pledget of purified cotton and in a dark place.—U. S.

The French Codex directs the distillation, by means of steam, of twice the weight of the fresh orange-flowers used. Thus prepared, it is called in commerce *double orange-flower water*, and if it is diluted with an equal weight of distilled water it is known as *simple orange-flower water*. The so-called *triple* and *quadruple orange-flower waters* are also met with in commerce, the former being obtained by distilling 3 parts, the latter by distilling 2 parts, of water from 2 parts of fresh orange-flowers.

Distilled orange-flower water is a clear and colorless or slightly opalescent liquid of a very agreeable odor and aromatic taste, which cannot be imitated by preparing the water from the oil of orange-flowers (neroli). As distilled from the flowers, it possibly contains some volatile ethers, which are freely soluble in water and not contained in the volatile oil. Occasionally, commercial orange-flower water separates mucilaginous flocks, which may be removed by agitation with powdered kaolin and filtration. If it has acquired an acid reaction, it is advisable to distil it over magnesia. The total absence of metallic salts, resulting from the use of a metallic condenser or from keeping the water in metallic vessels, is proved by its remaining unaffected by hydrogen sulphide and by ammonium sulphide. Occasionally, distilled orange-flower water has been met with which acquires a red color on the addition of an acid; the cause of this abnormal behavior has not been ascertained, but may perhaps be due to accidental impurity.

Action and Uses.—Orange-flower water is used as a pleasant lotion and vehicle for other drugs.

AQUA CAMPHORÆ, *U. S., Br.*—Camphor Water.

Aqua camphorata.—Eau camphrée, Fr.; *Kampherwasser*, G.; *Aqua alcanforada*, Sp.

Preparation.—Camphor, 8 Gm.; alcohol, 8 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Dissolve the camphor in the alcohol, triturate the solution with the purified talc, and, after allowing the greater part of the alcohol to evaporate spontaneously, continue the trituration with the water, gradually added; then pour the mixture upon a well-wetted filter, and pass the filtrate through the filter repeatedly until the camphor-water is perfectly clear.—U. S.

(120 grains of camphor, 120 minims of alcohol, and 240 grains of purified talc may be used in making 2 pints of camphor-water.)

The British Pharmacopœia directs that 70 grains (or 5 Gm.) of camphor be dissolved in sufficient alcohol (90 per cent.) to form ½ fluidounce (or 15 Cc.) of solution, which is then added in successive portions to 1 gallon, Imperial measure (or 5 liters), of distilled water, shaking after each addition and finally shaking until all camphor is dissolved. This preparation contains only about ¼ as much camphor as that of the United States Pharmacopœia, which latter aims to produce a saturated solution, for which purpose cold water only should be used. Saturated camphor water contains about 2 grains of camphor in each fluidounce, or 0.004 Gm. in each Cc.

Action and Uses.—See CAMPHORA.

AQUA CARUI, *Br.*—Caraway Water.

Aqua carui.—Eau distillée de carvi, Fr.; *Kümmelwasser*, G.

Preparation.—Take of caraway fruit bruised, 1 pound (or 500 Gm.); water, 2 gallons (or 10 liters). Distil one-half.—Br.

This water has the flavor of the fruit in a marked degree.

Action and Uses.—Caraway water is used as a vehicle to carry more potent drugs.

AQUA CHLORATA, *P. G.*—Chlorine Water.

Aqua chlori, U. S., 1890; *Chlorum solutum, Aqua oxymuriatica.—Solution of chlorine*, E.; *Eau chlorée, Chlore liquide*, Fr.; *Chlorwasser*, G.; *Acqua di cloro*, F. It.

An aqueous solution of chlorine containing at least 0.4 to 0.5 per cent. of the gas.—P. G.

Symbol, Cl. Atomicity univalent. Atomic weight, 35.18.

Origin.—Chlorine was discovered by Scheele (1774), and was first called dephlogisticated muriatic acid, afterward *oxymuriatic acid*, under the supposition that it was a compound of muriatic acid with oxygen. Gay-Lussac and Thénard (1809) showed that from its behavior it might be regarded as an element, a view which was strengthened by the researches of Humphry Davy (1810), who called it chloric gas, which name was changed to chlorine by Gay-Lussac (1813). Chlorine is widely distributed in nature, but owing to its affinity for other elements it is never found in the isolated state. It exists in many minerals, in most spring waters, in sea water, in plants, and in animals, and is liberated from the chlorides by the combined action of sulphuric action and an oxidizing agent.

Preparation.—Chlorine-water may be prepared by generating chlorine gas from a mixture of 35 Cc. of hydrochloric acid and 25 Cc. of water with 10 Gm. of manganese dioxide, in lumps of about the size of filberts, the whole being heated moderately to facilitate reaction. The gas is conducted through a wash-bottle containing 50 Cc. of water and then into a bottle of 1000 Cc. capacity containing 400 Cc. of previously boiled and cooled distilled water. The temperature best suited for dissolving the chlorine in water is 10° C. (50° F.), at which temperature water, according to Schoenfeld, dissolves 2.585 times its volume of the gas, the degree of solubility becoming gradually less as the temperature rises. The action of the acid on the manganese results in the liberation of chlorine and water, while manganese chloride is formed at the same time and remains in solution. When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating until the distilled water is saturated. Finally, pour the chlorine-water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled therewith, and keep them in a dark and cool place. Chlorine-water, even when kept from light and air, is apt to deteriorate. When it is required of full strength, it should be freshly prepared.

During the preparation and handling of chlorine-water the operator should be careful not to inhale the gas, on account of its irritating and poisonous properties. Should its effects be perceived, it is advisable to inhale carefully a little ammonium sulphide, which is decomposed by the chlorine into ammonium chloride and sulphur. It should, however, be cautiously used, since an excess of this compound is likewise poisonous. A little ammonia, sufficiently diluted, may also be taken with advantage.

For the preparation of chlorine on the large scale, as in the manufacture of chlorinated lime, sulphuric acid is sometimes used in addition to the manganese dioxide and hydrochloric acid, when all the chlorine contained in the latter is obtained and manganous sulphate is left in solution. Or the generation of hydrochloric acid and of chlorine is effected in one operation by the use of sulphuric acid, sodium chloride, and manganese dioxide, in which case the sulphates of sodium and of manganese remain behind.

For special purposes chlorine may be prepared by the action of hydrochloric acid upon potassium dichromate: $14HCl + K_2Cr_2O_7$ yield $3Cl_2 + 2KCl + Cr_2Cl_6 + 7H_2O$, the result being chlorine, potassium chloride, chromium chloride, and water. Or potassium chlorate may be decomposed by hydrochloric acid, with the formation of chlorine, potassium chloride, and water: $6HCl + KClO_3$ yield $3Cl_2 + KCl + 3H_2O$, but the gas is in this case apt to be contaminated with hypochlorous acid. At present much of the chlorine made on the large scale is obtained by the electrolysis of a solution of potassium chloride, which yields chlorine at the positive pole or anode and caustic potash and hydrogen at the negative pole or kathode: $2KCl + 2H_2O = 2KOH + H_2 + Cl_2$. It is obtained also as a by-product in the electrolysis of sodium chloride, magnesium chloride, and zinc chloride for the respective metals: $2NaCl = 2Na + 2Cl$. Most of the chlorine obtained thus is converted into bleaching-powder (Calx chlorata).

Properties.—Chlorine is a greenish-yellow, irrespirable, corrosive gas, having the specific gravity 2.45 as compared with air, and becoming liquid at 0° C. (32° F.) under a pressure of 6 atmospheres. Liquid chlorine is yellow, congeals at —102° C. (—151.6° F.), and boils at —33.6° C. (—28.48° F.). Chlorine is not inflammable, but is capable of supporting combustion.

Chlorine water is a clear, greenish-yellow liquid possessing the suffocating odor and acrid, irritating taste of chlorine, evaporating without residue, but separating crystals of chlorine hydrate when cooled to the freezing-point of water. Its specific gravity is 1.003 when saturated at 6° C. (42.8° F.) (Berthollet). It instantly discharges the color of diluted solutions of indigo and litmus, and bleaches vegetable coloring-matters generally. Exposed to light, it is decomposed into hydrochloric acid and oxygen. It is a powerful oxidizing agent, and this property serves to readily ascertain its strength. A fluidounce of it, mixed with a solution of 14 grains of pure ferrous sulphate, does not produce a blue precipitate with potassium ferricyanide, indicating that the salt has been completely oxidized to ferric sulphate, and proving that the water contains 0.4 per cent. of chlorine.

Tests.—Chlorine water should evaporate without residue. Agitated with an excess of mercury until the odor of chlorine has disappeared, the remaining liquid

reddens litmus-paper but faintly, if at all (limit of hydrochloric acid). The German Pharmacopœia requires that 28.2 to 35.3 Cc. of tenth-normal sodium thiosulphate solution shall be required to decolorize the deep-red liquid obtained by adding 25 Gm. of chlorine-water to a solution of 1 Gm. of potassium iodide in 5 Cc. of water.

The volumetric determination of the chlorine is indirectly accomplished, and is based upon the fact that chlorine is capable of displacing iodine and bromine in equivalent proportions; thus, $2KI + Cl_2 = 2KCl + I_2$. Each Cc. of tenth-normal sodium thiosulphate solution corresponds to 0.003518 Gm. of chlorine.

Action and Uses.—Chlorine water diluted one-third to one-half with pure water, or used even in its pure state, is employed locally as a stimulant and disinfectant upon superficial ulcers, and depends for its therapeutic power, of course, upon the chlorine gas which it contains. It has been employed as a gastro-intestinal antiseptic, in small doses well diluted, in such diseases as typhus and typhoid fever and in scarlet fever and diphtheria. But in none of these diseases is it a remedy to be depended upon. Probably its best use is as a gargle in cases of septic sore throat, diluted one-half with water.

AQUA CHLOROFORMI, *U. S., Br.*—Chloroform Water.

Eau de chloroforme, Fr.; *Chloroformwasser*. G.

Preparation.—Add enough chloroform to a convenient quantity of distilled water, contained in a dark amber-colored bottle, to maintain a slight excess of the former after the contents have been repeatedly and thoroughly agitated.

When chloroform water is required for use, pour off a sufficient quantity of the solution, refill the bottle with distilled water, and saturate it by thorough agitation, taking care that there be always an excess of chloroform present.—U. S.

Take of chloroform, 30 minims (or 2.5 Cc.); distilled water, 25 fluidounces (or 1000 Cc.). Shake together until the chloroform is entirely dissolved in the water.—Br.

Both pharmacopœias aim to produce a saturated aqueous solution of chloroform, the solubility of the latter substance in water being considered as about 1 in 200.

Action and Uses.—Chloroform water has been used as a gargle in sore throat, and internally in cases of neuralgia of the stomach and of gastro-intestinal flatulence. It is a moderately active antiseptic when used internally, and may be employed as a vehicle for organic substances which are apt to undergo fermentation or decomposition. Usually it is better to employ spirit of chloroform in internal medicine (see SPIRITUS CHLOROFORMI).

AQUA CINNAMOMI, *U. S., Br., P. G.*—Cinnamon Water.

Eau de canelle, Fr.; *Zimmtwasser*, G.; *Acqua distillata di cannella*, F. It., Sp.

Preparation.—Oil of cinnamon, 2 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the oil with the purified talc, add the water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the cinnamon-water is perfectly clear.—U. S.

(32 minims of oil of cinnamon may be triturated with 240 grains of purified talc, and will require 2 pints of distilled water.)

The British Pharmacopœia directs the distillation of 1 Imperial gallon (or 5 liters) of cinnamon water from 20 ounces (or 500 Gm.) of bruised Ceylon cinnamon. The German Pharmacopœia recognizes as *Aqua cinnamomi* a distilled water formerly called *Aqua cinnamomi spirituosa* (*s. vinosa*), and made by distilling 10 parts from a mixture of sufficient water, 1 part of alcohol (90 per cent.), and 1 part of Chinese cinnamon.

Made from the oil, cinnamon water has the odor and a somewhat harsh taste of cinnamon; but if distilled from the bark, its odor is more fragrant and its taste decidedly sweet. Cinnamon water made with magnesia has a yellowish color. In contact with the air the volatile oil is oxidized, and crystals of cinnamic acid and small particles of a brownish resin are sometimes separated.

Action and Uses.—Cinnamon water possesses slight stimulant and carminative properties, but is seldom used except as a vehicle for other medicines. It finds its most common employment in mixtures for flatulent colic and diarrhœa combined with such remedies as chalk, astringents, and opium. Its dose is 1 to 4 drachms (4–16 Cc.).

AQUA CREOSOTI, *U. S.*—Creosote Water.

Eau créosotée, Fr.; *Kreosotwasser*, G.

Preparation.—Creosote, 10 Cc.; distilled water, 990 Cc.; to make 1000 Cc. Agitate the creosote with the distilled water until dissolved, and filter through a well-wetted filter. Creosote-water should be freshly prepared when dispensed.—U. S.

(1 fluidrachm of creosote agitated with 99 fluidrachms of distilled water, and filtered, will furnish 12½ fluidounces of official creosote-water.)

Action and Uses.—Creosote-water has been used as a local application in cases of leucorrhœa and to ulcers. It is rarely used, but is sometimes of value to allay nausea. The dose is from 1 to 2 drachms (4–8 Cc.).

AQUA CRESOLICA, *P. G.*—Cresolated Water.

Kresolwasser, G.

Preparation.—Solution of cresol soap, 1 part; water, 9 parts.—P. G.

The German Pharmacopœia directs that distilled water shall be used if the preparation be intended for surgical purposes, in which case a yellowish clear solution will result. If cresolated water be prepared with ordinary water, it is likely to be turbid, but oily drops should not float on the surface. Cresolated water contains 5 per cent. of crude cresol and resembles carbolated water in odor.

Solution of cresol soap, Liquor Cresoli Saponatus, of the German Pharmacopœia is made by melting official soft soap on a water-bath, adding an equal weight of crude cresol and heating the mixture until a clear yellowish-brown solution results.

AQUA DESTILLATA, *U. S., Br., P. G.*—Distilled Water.

Eau distillée, Hydrolat simple, Fr.; *Destillirtes Wasser*, G.

Composition, H_2O. Molecular weight, 17.96.

Preparation.—Water, 1000 volumes; to make 800 volumes. Distil the water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first 100 volumes and throw them away. Then collect 800 volumes, and keep the distilled water in glass-stoppered bottles, rinsed with hot distilled water immediately before being filled.—U. S.

When ordinary water is heated to ebullition, the gases and volatile compounds dissolved therein are also vaporized and carried off with the vapors of the water, which, if condensed, would then be more highly charged with these volatile compounds; hence the necessity of rejecting the first portion of the distillate, as directed by the pharmacopœias. On the other hand, if the distillation is continued until all the water is vaporized from the still, the last portions are apt to be contaminated with volatile products resulting from the decomposition of ammonia compounds and organic matter. The pharmacopœias avoid this possibility by discontinuing the distillation when 15 per cent. of the water is left in the still.

The material of which the distillatory apparatus used for this purpose is constructed is of considerable importance, but more particularly in relation to the condenser. Iron, copper, and lead condensers should not be used, since the water corrodes these metals, traces and sometimes larger quantities of which will always be found in the distillate. Where a glass condenser is available, it may be regarded as the most desirable, apparatus made of metals (silver and platinum) which are not in the least corroded during distillation being too costly for general use. The material best adapted for practical purposes is block-tin, of which the condenser and all those portions of the apparatus should be made from which the vapors are made to descend. A minute quantity of tin is nearly always dissolved, but separates again on standing for a few days in contact with the air. The occasional appearance of confervæ in distilled water depends upon its direct contact with the air, and may be prevented by keeping it in vessels arranged in such a manner that the air can enter only after having passed through a layer of cotton, by which the spores are retained.

Distilled water as ordinarily prepared always contains a minute quantity of ammonia, but for some purposes it is necessary to have ammonia-free water. In such cases, carefully distilled water is redistilled with addition of acid potassium sulphate or a

little dilute sulphuric acid. Traces of ammonia are detected by Nessler's reagent (see AQUA AMMONIÆ).

Properties and Tests.—Distilled water is a colorless, limpid liquid, without odor or taste, and of a neutral reaction. On evaporating 1 liter of distilled water on a water-bath to dryness, not more than 0.075 Gm. of residue should remain. The transparency or color of distilled water should not be affected by hydrogen sulphide or ammonium sulphide (absence of metals), by test-solutions of barium chloride (sulphate), silver nitrate (chloride), ammonium oxalate (calcium), or mercuric chloride, with or without the subsequent addition of potassium carbonate (ammonia and ammonium salts). On heating 100 Cc. of distilled water acidulated with 10 Cc. of diluted sulphuric acid to boiling, and adding 1 Cc. of tenth-normal solution of potassium permanganate, the color of the liquid should not be entirely destroyed by boiling for 10 minutes, nor by afterward setting the vessel aside well covered for 10 hours (absence of organic or other oxidizable matters). Distilled water should not be affected when mixed with twice its volume of lime-water (absence of carbonic acid).—U. S. On continued exposure to the air distilled water will dissolve carbonic-acid gas, and then become cloudy with clear lime-water.

AQUA FŒNICULI, *U. S., Br., P. G.*—Fennel Water.

Eau de Fenouil, Fr.; *Fenchelwasser*, G.; *Acqua distillata di finocchio*, F. It.

Preparation.—Oil of fennel, 2 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the oil with the purified talc, add the water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the fennel water is perfectly clear.—U. S.

(32 minims of oil of fennel may be triturated with 240 grains of purified talc, and will require 2 pints of distilled water.)

Take of bruised fennel, 1 pound av. (or 500 Gm.); water, 1 gallon Imperial measure (or 10 liters). Distil one-half.—Br. The P. G. directs that 30 parts of distillate are to be collected for each part of fennel used. If good fennel be employed, the water last mentioned separates a small portion of oil on standing, and is therefore a saturated solution.

Action and Uses.—Fennel water, in combination with other remedies which are more powerful for this purpose, is used to expel flatus from the gastro-intestinal tract. Its dose is a teaspoonful (4 Cc.) or more as needed.

AQUA HAMAMELIDIS, *U. S.*—Hamamelis Water.

Liquor Hamamelidis—*Solution of Hamamelis*, Br.—*Witchhazel water, Witchhazel extract*, E.; *Eau de hamamelis*, Fr.; *Hamameliswasser*, G.

Preparation.—Take of hamamelis bark, 10,000 Gm.; water, 20,000 Cc.; alcohol, 1500 Cc. Macerate the hamamelis bark in the water during 24 hours; then distil until 8500 Cc. of distillate are obtained, add the alcohol, and mix thoroughly.—U. S.

This preparation should be made only from the fresh young twigs of hamamelis, collected for this purpose, preferably, when the plant is in flower, in the late autumn of the year. (See HAMAMELIS.) The addition of alcohol is partly for better preservation and partly perhaps to aid as a stimulant when the preparation is locally used.

The Br. P. directs that the preparation be made from fresh hamamelis leaves by macerating 1000 Gm. for 24 hours in a still with a mixture of 2000 Cc. of water and 200 Cc. of 90 per cent. alcohol, and then distilling one-half.

Hamamelis water is a clear colorless liquid having a peculiar odor, which to some persons is quite unpleasant. The U. S. P. requires that if 1 Cc. of hamamelis-water be added to 5 Cc. of sulphuric acid, containing a little salicylic acid in solution, no red color should appear (absence of formaldehyde).

Action and Uses.—For the action and uses of Aqua Hamamelidis, see HAMAMELIDIS FOLIA.

AQUA HYDROGENII DIOXIDI, *U. S.*—Solution of Hydrogen Dioxide.

Liquor Hydrogenii Peroxidi, Br.; *Solution of Hydrogen Peroxide*, E.; *Soluté de peroxide d'hydrogen*, Fr.; *Wasserstoff hyperoxidlösung*, G.; *Acqua ossigenata*, F. It.

A slightly acid aqueous solution of hydrogen dioxide, containing, when freshly prepared, about 3 per cent. by weight of the pure dioxide, corresponding to about 10

volumes of available oxygen. It should be kept in a cool place. Upon removing the stopper from the bottle not more than a slight pressure should be observed.—U. S.

Formula, H_2O_2. Molecular weight, 33.76.

History and Occurrence.—Thénard (1818) discovered hydrogen dioxide, which has also been called *oxygenated water* and *oxygen hydrate*, by acting with dilute acids upon barium peroxide.

It occurs in minute quantity in the atmosphere after storms and heavy snowfalls, and is formed in many oxidation processes that take place in the presence of water. It is also formed whenever ozone is generated in the presence of water, as ozone easily breaks down with water into hydrogen peroxide, for example, when terpenes are brought in contact with water and air. It is formed in solution whenever certain peroxides—for example, Na_2O_2, K_2O_2, BaO_2—are treated with dilute acids, such as HCl, H_2SO_4, HF: $Na_2O_2 + 2HCl = 2NaCl + H_2O_2$. The reaction is exactly analogous to that which takes place when an oxide and an acid react; thus, $Na_2O + 2HCl = 2NaCl + H_2O$; but in the latter case, water or *hydrogen monoxide* is formed, while in the former case *hydrogen dioxide* is obtained.

On the large scale barium dioxide is used, and such acid is chosen as will give with barium an insoluble compound, thus leaving an approximately pure aqueous solution of the hydrogen peroxide. Sulphuric or hydrofluoric acid is used, giving in the one case insoluble barium sulphate and in the other insoluble barium fluoride, which are removed by filtration from the solution of hydrogen dioxide. Barium dioxide may also be decomposed by suspending it in water and passing carbon dioxide through the mixture: $BaO_2 + CO_2 + H_2O = BaCO_3 + H_2O_2$, insoluble barium carbonate being formed. In all methods of preparation the temperature should be kept down nearly to 0° C. (32° F.), to avoid decomposition of the dioxide.

Preparation.—The U. S. P., 1890, gave the following process: Barium dioxide, about 10½ avoirdupois ounces (300 Gm.); phosphoric acid, diluted sulphuric acid, distilled water, of each a sufficient quantity. Pour about 16 fluidounces (500 Cc.) of cold distilled water into a suitable bottle, add to it the barium dioxide in such a way that it does not form lumps, and shake vigorously, so that a uniform mixture may result. Provide suitable means of refrigeration, so that the bottle and its contents may be kept at a temperature below 10° C. (50° F.), and shake it thoroughly every few minutes during half an hour. Afterward, continuing the refrigeration, shake it occasionally, but vigorously, until the dioxide has become fully hydrated, which may be recognized from the fact that only a small portion of the water separates from it on standing, and that it may be mixed with the separated water without great effort by shaking. Having introduced about 3¼ fluidounces (96 Cc.) of phosphoric acid into a bottle having the capacity of about 67 fluidounces (about 2000 Cc.), add to it about 10¾ fluidounces (320 Cc.) of distilled water, cool the mixture and remove about 1⅔ fluidounces (50 Cc.) as a reserved portion. Now add the well-mixed magma to the acid liquid, and mix them intimately by frequent stirring and shaking, cooling the bottle if necessary. From time to time test the reaction of the liquid, and, when it becomes alkaline, add to it, cautiously, a little of the reserved phosphoric acid, until the liquid has again acquired an acid reaction. Repeat the agitation or stirring from time to time, and also the cautious addition of phosphoric acid, until the liquid, after standing for some time, no longer is alkaline, and at most is only slightly acid. Having finally shaken the bottle again thoroughly, set it aside until the precipitate occupies only about one-third of the volume of the contents, and pour the supernatant liquid upon a wetted, double, rapidly acting white filter, of a diameter of 30 Cm. Then transfer the semi-liquid precipitate to the filter, rinse the bottle with about 3½ fluidounces (100 Cc.) of distilled water, transfer this to the filter, and when the liquid has drained off wash the barium phosphate on the filter with distilled water until the filtrate measures about 34 fluidounces (1000 Cc.). Now add to it, first, 20 drops, and afterward, if necessary, smaller quantities of diluted sulphuric acid, until a small portion of the liquid, after filtration (which may be assisted by a little starch), is no longer rendered cloudy by diluted sulphuric acid. Mix the cloudy liquid with 150 grains (about 10 Gm.) of starch by agitation, so that the starch may be thoroughly distributed throughout the liquid, and then filter it through a well-wetted white filter of a diameter of 25 Cm., returning the first portions until the filtrate is clear. When all the liquid has passed, ascertain the percentage of hydrogen dioxide contained in it by the method of assay given below and dilute the remaining liquid if necessary, so that it will contain 3 per cent of absolute hydrogen dioxide. Keep the product in loosely stoppered bottles, in a cool place.

Since solution of hydrogen dioxide will gradually diminish in strength, even when carefully kept, it should either be freshly made when wanted or kept on hand only in such quantity as will probably be consumed within a short time.

Properties.—Solution of hydrogen dioxide is a colorless, odorless liquid, having at 15° C. (59° F.) a specific gravity of 1.006 to 1.012. It has a slightly acidulous taste,

and produces a peculiar sensation and soapy froth in the mouth. Its acid reaction is due to the small amount of acid purposely added for preservation. It decomposes by age, exposure to heat, and protracted agitation, into water and free oxygen. Exposed to the air or cautiously heated on a water-bath to a temperature not above 60° C. (140° F.), it loses chiefly water; but if rapidly heated, it is apt to decompose with explosive violence. If a few Cc. of ether be poured upon a mixture of 10 Cc. of distilled water, 1 drop of potassium chromate test-solution, and 10 drops of diluted sulphuric acid, a blue color will appear at the line of contact upon addition of a few drops of hydrogen dioxide solution. After shaking, the ethereal layer will separate with a blue color.

Absolute hydrogen dioxide has been prepared by evaporating a dilute solution on a water-bath at a temperature not above 75° C. (167° F.) till it reaches about 50 per cent. and then distilling in a vacuum, when water comes over first, and finally nearly pure dioxide. By repeated fractionation in this manner, a dioxide containing 99.1 per cent. has been obtained. It is a thick, oily, colorless liquid, specific gravity 1.499, and boiling at 69° C. (156.2° F.) under a pressure of 26 Mm. It does not congeal at —30° C. (—22° F.). It volatilizes slowly in vacuo and without decomposition at ordinary temperatures. When exposed to sunlight, or when heated, or when brought into contact with charcoal, silver, gold, the platinum metals, the oxides of manganese, alkalies, or various other compounds, the dioxide is decomposed, often with explosive violence, and in presence of the oxides of the metals mentioned these are reduced to the metallic state. A number of other bodies act less energetically and are oxidized. Litmus- and turmeric-paper are gradually bleached. The dioxide is odorless and has a harsh and bitter taste; applied externally, it colors the skin white and causes violent itching. Because of its instability and liberation of oxygen, it is a very powerful and useful oxidizing agent. It liberates iodine from iodides, and converts arsenous and sulphurous into arsenic and sulphuric acids. Many organic substances are decomposed by it, as blood, pus, etc. In some instances it acts as a reducing agent. Easily reducible oxides, as those of silver, gold, and platinum, are reduced to metal; thus, $Ag_2O + H_2O_2 = 2Ag + H_2O + 2O$. Chromic acid and permanganic acid are reduced by it, with escape of oxygen gas; also hypochlorites.

Many practical uses are made of hydrogen dioxide solution. It is largely used as a bleaching agent, especially for delicate objects, as, for example, Tussah silk, ostrich feathers, ivory, human hair, old engravings, and paintings. It is used in textile industries to bleach, and also to decompose hypochlorites and sulphites, which cling tenaciously to fabrics. It is also an excellent antiseptic.

Tests.—If to 25 Cc. of the solution 5 Cc. of tenth-normal potassium hydroxide solution be added, and the mixture evaporated to about 10 Cc., and 3 drops of phenolphthalein added, not less than 35 Cc. of tenth-normal sulphuric acid should be required to discharge the red color of the solution after continued boiling (limit of free acids). If 20 Cc. of the solution be evaporated to dryness upon a bath of boiling water, and the drying completed at 120° C. (248° F.), not more than 0.03 Gm. of solid residue should remain (limit of total solids). If to 1 Cc. of the solution 1 Cc. of ammonia-water be added, and the solution evaporated to dryness upon a bath of boiling water, the residue should not respond to the modified Gutzeit's test for arsenic (see ARSENI TRIOXIDUM). If to 1 Cc. of the solution 1 Cc. of ammonia-water be added and evaporated to dryness upon a bath of boiling water, the residue, when dissolved in 10 Cc. of distilled water containing 1 Cc. of diluted hydrochloric acid and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen sulphide solution after standing, well stoppered, in a warm place—35° C. (95° F.)—for at least half an hour, nor should the further addition of ammonia-water to this solution cause a coloration or turbidity therein (absence of heavy metals). Upon evaporating 50 Cc. of the solution, previously rendered alkaline by sodium hydroxide test-solution, to dryness upon a water-bath, transferring the dry residue to a watch-glass, moistening it with sulphuric acid, and setting the glass in a moderately warm place for a few hours, the surface of the glass, after being washed, should exhibit no sign of corrosion (absence of hydrofluoric acid). The addition of a few drops of diluted sulphuric acid to 10 Cc. of the solution should produce no turbidity or precipitate (absence of barium).—U. S.

The Pharmacopœia gives the following method for ascertaining the strength of a solution of hydrogen dioxide: Dilute 10 Cc. of the solution with distilled water sufficient

to measure 100 Cc. Transfer 16.9 Cc. of this liquid (containing 1.69 Cc. of the solution) to a beaker, add 5 Cc. of diluted sulphuric acid, and then, from a burette, slowly add, with constant stirring, tenth-normal potassium permanganate solution until the liquid just retains a faint pink tint. Each Cc. of tenth-normal potassium permanganate solution consumed corresponds to 0.1 per cent. of absolute hydrogen dioxide, or 0.329 volumes of oxygen.

To express the strength in *percentage (by weight) of absolute hydrogen dioxide*, multiply the number of Cc. of tenth-normal potassium permanganate solution decolorized by 1 Cc. of it by 0.169, or divide the number of Cc. of tenth-normal potassium permanganate solution decolorized by 1.69 Cc. of it by 10.

The Br. P. requires 1 volume of solution to yield 18–22 volumes of oxygen gas when assayed by means of an acidified solution of permanganate of potassium in a nitrometer filled with brine, corresponding to a 9–11 volume solution.

Action and Uses.—Hydrogen peroxide is used for the purpose of cleansing ulcerating surfaces, for the removal of the false membrane of diphtheria and of the exudate in tonsillitis, and it is sometimes applied to the skin for the purpose of removing discolorations by virtue of its bleaching powers. There is no local application which compares with the peroxide of hydrogen for the removal of the false membrane of diphtheria. When it comes in contact with blood, pus, or other organic material, it sets free a very considerable portion of its oxygen and active effervescence ensues. Applied to ulcers, it speedily softens and removes pus and inflammatory exudates, and leaves a cleansed surface, which may be adequately treated by the application of such substances as are needed in the acceleration of healing.

Peroxide of hydrogen ought never to be injected into body cavities unless the opening in the cavity is large enough to admit of the ready escape of the gas which is set free; for if the gas is imprisoned, it forces apart the inflammatory exudate which is protecting the surrounding parts from infection, and so tends to increase the area of disease. This is particularly important in cases of fistula in ano, and in sinuses which communicate with dead bone. Peroxide of hydrogen has been administered internally as a gastric antiseptic, but is probably of little value, and its internal use, with the idea that it will give off oxygen which can be absorbed into the blood and utilized by the system, is based upon a lack of knowledge of its composition and physiological action. If any oxygen is absorbed from it when it enters the stomach, the amount is so infinitesimal as to be without effect.

When hydrogen peroxide is applied to the throat in diphtheria or in tonsillitis, it should be used in an atomizer made of glass or hard rubber, or applied by means of a piece of cotton on an applicator. It has been used as a gargle in septic sore throat, but it is apt to exert an effect upon metallic fillings in teeth, and if it comes in contact with a carious spot in a tooth may produce a great deal of pain.

Allied Compounds.—It has been known since 1858 that acid esters of hydrogen dioxide could be obtained by the action of acetyl or benzoyl chloride, or acetic or benzoic anhydride, on barium dioxide, and in 1896 Vanino and Thiele published methods for preparing benzoyl dioxide from sodium dioxide by action of benzoyl chloride (*Ber. d. d. chem. Gesellsch.*, 1896, p. 1724). Later Drs. Freer and Novy of the University of Michigan prepared benzoyl-acetyl dioxide and named it benzozone, which name was afterward changed to

Acetozone.—This compound, $(C_6H_5CO.COCH_3)O_2$, resembles hydrogen dioxide in structure, and occurs in crystals which melt at about 36.6° C. (98° F.). It is soluble in water in proportion of 1 part in 1000 to 10,000 parts, according to the temperature of the water; also soluble in 35 parts of oil, slightly soluble in alcohol, and fairly so in ether and chloroform. When dissolved in liquids other than neutral petroleum oils it is gradually decomposed. Acetozone also decomposes in contact with alkalies, or when gradually heated. While not itself an oxidizing agent, its aqueous solutions, owing to slow hydrolysis, act as such.

Acetozone is highly recommended as an intestinal antiseptic in the treatment of typhoid fever, in which disease it is claimed to lessen the tendency to tympanites and diarrhœa, to destroy the offensive odor of the stools, to abate nervous symptoms, and to reduce temperature. At least 2 quarts of the 1 : 2000 solution should be drunk in 24 hours, the solution replacing all other liquids except milk. It is used also in diarrhœa, amœbic dysentery, Asiatic cholera, and other intestinal diseases, administered by the mouth and by high rectal injection. Its antiseptic power renders it an efficient application in tonsillitis and other throat affections, corneal ulcers, gonorrhœal urethritis and vaginitis, in abscesses, gangrene, and minor surgical cases. For these purposes it may be applied in powder, aqueous or oily solution or ointment. For internal administration acetozone is preferably dissolved in *warm* water in the proportion of 7½ grains to 1 quart (about 1 : 2000). If given in powder or cap-

sule it may irritate the stomach. Ointments of acetozone should be made with petrolatum and of the strength of $\frac{1}{10}$ to 1 per cent., while for use as a spray it may be dissolved in liquid petrolatum previously warmed to about 55° C. (131° F.). Commercial acetozone, as marketed by Parke Davis & Co., is in the form of powder, and is said by the manufacturers to be a mixture of equal weights of pure acetozone and an inert absorbent substance.

GLYCOZONE.—This is claimed by the manufacturer, Marchand, to be a stable chemical compound resulting from the reaction taking place when chemically pure glycerin is treated with 15 times its own volume of ozone. It has a pleasant sweet acidulous taste and absorbs moisture quite readily, hence must be kept in well-stoppered bottles to prevent deterioration. Glycozone is claimed by its manufacturer to give relief when given internally in catarrhal and in inflammatory conditions of the stomach, and in intestinal disorders, and when applied locally to stimulate healthy granulations in ulcers, etc.

HYDROZONE.—This name has been applied by Marchand to an aqueous solution of hydrogen peroxide about 3 times as strong as the official solution, yielding not less than 30 volumes of available nascent oxygen, and containing 9 per cent. of hydrogen dioxide. With ordinary care it is said not to lose more than $\frac{1}{10}$ of 1 volume of oxygen every 30 days, at a temperature not exceeding 21.1° C. (70° F.), and must, therefore, be considered as quite stable. Hydrozone is used for the same purposes as Aqua Hydrogenii Dioxidi.

AQUA LAUROCERASI, *Br.*—Cherry-laurel Water.

Eau distillée de laurier-cerise, Fr.; *Kirschlorbeerwasser*, G.

Preparation.—Take of fresh leaves of cherry laurel, 1 pound (or 320 Gm.); water, 2½ pints (or 1000 Cc.). Crush the leaves, introduce them with the water into a retort, and distil 1 pint of liquid (or 400 Cc.). Shake the product, filter through paper, and adjust the strength of the finished product either by addition of hydrocyanic acid or by diluting the filtrate with distilled water, so that 20 Gm. of it, tested as described under Hydrocyanic Acid, shall require 3.7 Cc. of the volumetric solution of silver nitrate to be added before a permanent precipitate begins to form, which corresponds to 0.1 per cent. of real hydrocyanic acid.—Br.

The distillate contains oil of bitter almond and hydrocyanic acid, and is similar to bitter-almond water.

Action and Uses.—Cherry-laurel water depends for its properties upon the small quantity of hydrocyanic acid which it contains, amounting to about $\frac{1}{10}$ of 1 per cent. Because of the volatility of its active principle it varies greatly in strength, sometimes producing effects which are excessive and at other times being almost devoid of influence. Like most medicinal waters, it is used chiefly as a vehicle because of its pleasant taste of bitter almond. Its dose is from ½ to 2 teaspoonfuls (2–8 Cc.), the latter dose being administered with caution.

AQUA MENTHÆ PIPERITÆ, *U. S., Br., P. G.*—Peppermint Water.

Eau de menthe poivrée, Fr.; *Pfefferminzwasser*, G.; *Acqua distillata di menta piperita*, F. It.

Preparation.—Oil of peppermint, 2 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the oil with the purified talc, add the water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the peppermint-water is perfectly clear.—U. S.

(32 minims of oil of peppermint may be triturated with 240 grains of purified talc, and will require 2 pints of distilled water.

Take of oil of peppermint, 77 minims (or 10 Cc.); water, 1½ gallons (or 15 liters). Distil two-thirds.—Br.

The German Pharmacopœia directs 10 parts of water to be distilled from 1 part of the herb; Fr. Cod., 1 part from 1 part of the fresh herb.

Action and Uses.—Peppermint water when freshly prepared has quite a strong odor and taste of peppermint, and is chiefly used as a vehicle in the administration of drugs which are designed to cure indigestion and to expel flatus from the gastro-intestinal tract. Peppermint water is sometimes given in the dose of from ½ to 1 teaspoonful (2–4 Cc.), pure or diluted with water, in the treatment of colic in children. It is also sometimes used with bicarbonate of sodium in the treatment of headache, hiccough, and cardiac palpitation dependent upon hyperacidity of the stomach.

AQUA MENTHÆ VIRIDIS, *U. S.*, *Br.*—Spearmint Water.

Eau de menthe verte, Fr.; *Römisch-Minzwasser*, G.; *Agua de yerba buena*, Sp.

Preparation.—Oil of spearmint, 2 Cc.; purified talc, 15 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the oil with the purified talc, add the water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the spearmint-water is perfectly clear.—U. S.

(32 minims of oil of spearmint may be triturated with 240 grains of purified talc, and will require 2 pints of distilled water.)

Take of oil of spearmint, 77 minims (or 10 Cc.); water, $1\frac{1}{2}$ gallons (or 15 liters). Distil two-thirds.—Br.

On the continent of Europe curled mint-water is used instead. *Aqua menthæ crispæ* is prepared by mixing curled mint-leaves, 1 part, with sufficient water, and distilling 10 parts.

Action and Uses.—Spearmint is used in cases of infantile colic with bicarbonate of sodium, in the dose of a teaspoonful, for the expulsion of flatus from the gastro-intestinal tract, and as a vehicle for other drugs. Its dose is from $\frac{1}{2}$ to 4 teaspoonfuls (2–8 Cc.).

AQUA PICIS, *P. G.*—Tar Water.

Theerwasser, G.; *Acqua di catrame*, F. It.; *Agua de alquibran*, Sp.

Preparation.—1 part of tar is mixed with 3 parts of powdered pumice-stone which has been previously washed with water and dried, and of this mixture 2 parts are added to 5 parts of water, well shaken for 5 minutes, and filtered.—P. G. Tar, 1 part; water, 46 parts.—F. It.

Tar water should be clear, of yellowish or brownish-yellow color, and possess the odor and taste of tar. It is best prepared fresh when wanted.

Action and Uses.—Tar water is sometimes used in cases of intestinal catarrh and of bronchitis in its chronic forms.

Aqua Picis Concentrata.—*Concentrated tar water*, E.; *Starkes Theerwasser*, G.—250 parts of tar are mixed with 15 parts of sodium bicarbonate and 1000 parts of water, and warmed in a closed vessel on a water-bath for 3 hours. When cool, the mixture is filtered.

AQUA PIMENTÆ, *Br.*—Pimento Water.

Eau de piment de la Jamaïque, Fr.; *Nelkenpfeffer-Wasser*, G.

Preparation.—Take of pimento, bruised, 8 ounces (or 250 Gm.); water, 2 gallons (or 10 liters). Distil one-half.—Br.

On standing, it separates a brownish resin.

Action and Uses.—Pimento water has been used for wind colic and as a vehicle.

AQUA ROSÆ, *U. S.*, *Br.*, *P. G.*—Rose Water.

Aqua Rosarum.—Eau distillée de rose, Fr.; *Rosenwasser*, G.; *Acqua distillata di rose*, F. It.; *Agua rosada*, Sp.

Preparation.—Stronger rose water, distilled water, of each, 1 volume. Mix them immediately before use.—U. S.

The British Pharmacopœia directs that rose water shall be prepared by mixing the distilled rose water of commerce with twice its volume of distilled water immediately before use.

Add 4 drops of oil of rose to 1000 Cc. (about 34 fluidounces) of lukewarm water, agitate for some time, and filter.—P. G.

Action and Uses.—Rose water is used as a vehicle.

AQUA ROSÆ FORTIOR, *U. S.*—Stronger Rose Water.

Triple rose-water, E.; *Stärkeres Rosenwasser*, G.

Water saturated with volatile oil of rose petals, obtained as a by-product in the distillation of oil of rose.

Strong rose water should be kept in well-stoppered bottles, in a dark place.—U. S.

Like orange-flower water, the finest rose water is obtained by distillation of the fresh

petals; it should be clear and colorless, not mucilaginous, and free from metallic impurities, which latter may be detected by hydrogen sulphide and ammonium sulphide, neither of which should produce turbidity in the water.

AQUA SAMBUCI, *Br.*—Elderflower Water.

Eau distillée de sureau, Fr.; *Fliederblumen- (Hollunderblüthen-) Wasser*, G.

Preparation.—Take of fresh elderflowers, separated from the stalks, 10 pounds (or 5000 Gm.) (or an equivalent quantity of the flowers preserved while fresh with common salt); water, 5 gallons (or 25 liters). Distil one-fifth.—Br.

On standing, it is inclined to separate a mucilaginous sediment, which should be removed by filtration.

AQUÆ MEDICATÆ.—Medicated Waters.

Aquæ destillatæ, P. G.; *Aquæ stillatitiæ.—Distilled waters*, E.; *Eaux distillées, Hydrolats*, Fr.; *Destillirte Wässer*, G.; *Acquæ distillate*, F. It.

Preparation and Properties.—The above names are applied to waters which have been impregnated with volatile substances. All odorous plants and parts of plants impart their odor, and to a certain extent also their taste, to water which is distilled therefrom. This is due to a considerable extent to the volatile oils passing over with the vapor of water; but in many instances the flavor of such distilled waters differs more or less from that of the aqueous solutions of the corresponding volatile oils, and we may therefore assume that besides the volatile oils and other volatile compounds, acids, and probably ethers, pass over and remain dissolved in the water, whereby the flavor is modified and nearly always becomes more agreeable. In preparing medicated waters distillation should be resorted to whenever practicable.

The drugs are preferably used in the fresh state if they can be thus obtained, since during the drying process more or less of the volatile constituents are lost by evaporation, and, in common with the others, often modified in composition. In some cases where the oil-cells are well protected, as in cinnamon bark, or the oil is produced only by contact with water, as in bitter almond, the material may be preserved in the dry state for a long time without deterioration. In all cases where the oil-cells are not situated on the surface, as they are in many leaves, the drug should be suitably comminuted, so that it may be easily penetrated by the hot water and the oil-cells ruptured.

In distilling medicated waters over a naked fire great care should be taken to prevent the material from being burned, otherwise an empyreumatic odor and taste will be imparted to the distillate; this is obviated by placing the drug upon a diaphragm, or setting within the still another vessel perforated on the sides and bottom, so that the vapors will pass through it without unnecessary obstruction. If steam is used, the danger of burning is avoided; in this case a jet of steam may be conducted to the bottom of the still, the contents of which are thereby heated to the boiling-point. If dry material is used, allowance should be made for its swelling on becoming thoroughly permeated by the water, as it might otherwise fill the still and pass into the condenser. Some materials when boiled in water foam considerably, and portions of the decoction are then apt to be carried over mechanically, rendering the distillate colored and otherwise impure. This tendency to foam over will be lessened by adding to the contents of the retort a small quantity of a fixed oil.

The rapidity with which medicated waters are distilled is of importance, since it has a considerable influence on their flavor and stability. In all cases the waters should be rapidly and thoroughly cooled in the condenser, to prevent the action upon the tin of the hot water and of the acids which are frequently present, and to avoid changes in the volatile oil which, in its finely divided condition, are apt to occur. Waters which have been insufficiently cooled very frequently become ropy in keeping. It is advisable, therefore, to distil them slowly, and to cool the condenser well with a sufficient supply of water.

A peculiar odor is observed in some waters immediately after they have been distilled from tin vessels or condensed in tin worms, but not when glass vessels have been used. If the waters are exposed to the air in loosely closed vessels for a few days, this still-odor disappears and the natural odor of the water becomes apparent.

Distilled waters which, like orange-flower and rose-water, are not completely saturated with volatile oil, are advantageously prepared of double or triple strength, either by distilling off only one-half or one-third of the necessary quantity of water, or by having recourse to the process of cohobation, in which case the proper quantity of water is distilled off and a second or third time distilled from fresh portions of the same material. When wanted for use, they are diluted with distilled water in the proper proportions.

Distilled waters are best preserved in well-corked bottles, which should be completely filled and protected from the light. Exposed to air and light, they gradually turn sour and lose their agreeable odor.

The U. S. Pharmacopœia directs most medicated waters to be prepared by dissolving the volatile oil in distilled water, the intention being to produce, as nearly as possible, saturated solutions, which must be clear and free from solid impurities. To facilitate solution, the oils are now directed to be triturated with about 8 times their weight of purified talc, after which the distilled water is gradually added with continued trituration; the mixture is finally filtered through paper. Thorough trituration with an insoluble powder causes division of the oils into minute particles, in which condition they are more readily dissolved by water. It is important that the purified talc be not used in the form of an impalpable powder, as this is apt to pass through the filter and necessitate frequent refiltration, but a coarser powder, about No. 60 or No. 80, should be employed. Permission is also given in the Pharmacopœia to effect solution of the volatile oil by replacing the purified talc by pulped or shredded filter-paper, or by the addition of oils to hot water and separation of the excess of the former after active agitation and subsequent cooling of the mixture, or by distillation of the drug or oil with water. When shredded filter-paper is used, the best plan is to drop the oil upon the shredded paper, add this to the hot distilled water contained in a strong bottle or jug, and shake actively until the liquid is cold, after which a perfectly clear solution may be obtained by simple filtration. In our experience this method produces excellent results with little labor. The use of alcohol for the purpose of facilitating solution of the oil in the water must be condemned as liable to cause trouble, the very weak alcoholic liquid having a tendency to become sour through oxidation under favorable conditions. Calcium phosphate, directed in the U. S. P., 1890, is not a good medium for division of the oils, and is frequently found impure from contamination with soluble matter. Magnesium carbonate, at one time largely used, is not desirable, as it is not wholly insoluble, and this fact has often given rise to trouble, as in the case of cinnamon-water, which invariably has a yellow color when made with this agent, and in the case of mixtures of medicated waters with lime-water, producing turbidity.

Tests for Purity.—Medicated waters should evaporate in a clean porcelain capsule without appreciable residue. The water should not acquire a brown or black color by ammonium sulphide or hydrogen sulphide (metals), nor yield with the former a white sediment after having been previously rendered alkaline by the addition of ammonia (zinc).

Action and Uses.—Medicated waters are employed almost exclusively as vehicles for more powerful drugs which are dissolved in them. Very few of them are administered for their own medicinal properties. Statements in regard to the therapeutic uses of each of these will be found under their appropriate headings.

AQUÆ MINERALES.—Mineral Waters.

Eaux minérales, Eaux médicinales, Fr.; *Mineralwässer,* G.

These are spring waters which are charged with certain gases or salts to such a degree that they are unfit for ordinary use, having a noticeable taste and appreciable effect on the animal organism. If the temperature of the water is higher than that of the atmosphere, the springs are known as *thermal,* or *hot,* otherwise they are called *cold springs.*

According to the predominant constituent present, the springs are divided into the following classes:

1. Sulphuretted Waters contain sulphides and hydrogen sulphide, in consequence of which they possess a more or less fetid odor. Some of them are colored or yield a colored deposit, from which fact they have received such names as white (deposit of sulphur), red (iron oxide), blue (from slate), or yellow (due to polysulphides). In this country many sulphur springs exist, the following being some of the most noted:

Cold.—Olympian, Paroquet, Big Bone, Upper and Lower Blue Lick, all of Kentucky; Columbia, Massena Sharon, Clifton, and Chittenango, of New York; White, Red, and Blue Sulphur, Greenbrier White Sulphur, Yellow Sulphur, of Virginia; Salt Sulphur, Red Sulphur, and Borden Spring, of West Virginia.

Thermal.—Santa Barbara (15.5°–54.4° C., 60°–130° F.), Paso Robles (44.4°-50° C., 112°–122° F.), Calistoga, of California; Warm Springs (36° C., 97° F.), of Virginia and of Georgia (32° C., 89.6° F.); Warm Sulphur Springs (35.5°–40° C., 96°–104° F.) of Colorado; Warm Sulphur Springs (35.5°–40° C., 96°–104° F.) of Alaska.

The chief springs in Europe are—

Cold.—Harrowgate, Old Sulphur Well (England); Montmorency (France); Weinberg. Nenndorf, Langenbrücken (Germany).

Thermal.—Barèges, St. Sauveur, Eaux-Chaudes, in France; Baden, in Austria; Aix-la-Chapelle, Aix-les-Bains (Savoy).

2. Alkaline Waters, in which sodium carbonate predominates and free carbonic acid is often present in considerable quantity. Potassium and magnesium carbonates are also present. The following are a few noted springs: Ems, Salzbrunn, Fachingen, in Germany; Vichy, Carnares, in France; Bristol and Buxton, in England; Bladon Springs, in Alabama; Gettysburg Spring, in Pennsylvania.

3. Saline Waters contain various salts of alkalies and alkaline earths, occasionally bromides and iodides. The most common salts are sulphates, carbonates, and chlorides, the latter being the principal one. The following are American springs:

Saratoga, Ballston Spa, Albany Artesian Wells, of New York; Hot Springs, of Virginia; Sweet Springs, of West Virginia; Yellow Springs, Ohio; Bethesda, Wisconsin.

Celebrated European springs are: Selters, Apollinaris, of Germany; Bath, Cheltenham Royal Old Wells, of England; Carlsbad, of Bohemia; Plombières, of France.

4. Purgative Waters, so named because of a purgative action due to sulphates of the alkalies and magnesium, and called by the Germans *Bitterwasser*. Some of them contain iron compounds.

Some American waters are: Bedford Springs, of Pennsylvania; Estile, Crab Orchard, and Harrodsburg Springs, of Kentucky.

European Springs are: Friedrichshall, in Saxe-Meiningen; Seidlitz; Hunyadi János, Ivanda Pullna, of Austria; Kissingen, of Germany; Epsom, of England.

5. Chalybeate Waters, embracing those springs which contain iron in sufficient quantity to impart to them a ferruginous taste. The iron is present either as sulphate or frequently as ferrous carbonate, held in solution by excess of carbonic acid. Hydrogen sulphide is present in some of these springs. Iron being found in several of the waters named above in larger quantities than mere traces, it is evident that the classification must be somewhat arbitrary.

Spa, Pyrmont, Schwalbach, Homburg, are in Germany; Brighton, Cheltenham (chalybeate), Tunbridge Wells, in England; Anderson's Spring, Pa.; Rawley Springs, Va.; Cooper's Well, Miss.; Ballston Spa, New York.

6. Thermal Springs.—Their temperature is above that of the locality in which they are situated, and they serve an important use for baths, although most of these waters are also used internally. The following are some of the best known:

Carlsbad, 73.5° C. (172.4° F.); the temperature of 8 other hot springs ranges between 60.2° and 40° C. (140.4° and 109.4° F.) (Austria). Wiesbaden (Kochbrunnen), 68.8° C. (155.8° F.) (Germany). Baden-Baden, the temperature of 9 springs ranges between 68.63° and 44.4° C. (156° and 112° F.) (Germany). Hot Springs, Arkansas, the 57 springs range in temperature between 65.5° and 33.9° C. (157° and 76° F.). Mention should also be made of the Hot Springs of South Dakota, temperature 36.6° C. (98° F.), and at Glenwood, Colorado, temperature 51.11° C. (124° F.). Aix-la-Chapelle (Aachen), 4 springs ranging between 55° and 45.4° C. (131° and 113.7° F.) (Germany). Bath (King's Spring), 46.2° C. (115° F.) (England). Gastein (Wildbad), 49° to 25° C. (120.2° to 77° F.) (Austria). Ems, 13 springs, ranging between 46.6° and 27.9° C. (116° and 82.2° F.) (Germany). Idaho Springs, Colorado, 46.1° to 29.5° C. (115° to 85° F.). Vichy, 8 springs, 43.5° to 22° C. (108.5° to 71.6° F.) (see under Alkaline Waters). Hot Springs, Virginia, 43.3° to 25.5° C. (110° to 78° F.). Plombières, 51.6° C. (125° F.) (France). Teplitz, 48.8° C. (120° F.) (Bohemia).

Artificial Mineral Waters have been manufactured and used for many years both in Europe and the United States; many of these are close imitations of the natural waters and are extensively sold.

Action and Uses.—Spring water when pure is often taken in large quantities for the purpose of flushing the kidneys and the bladder and aiding in the elimination of impurities from the body. Often its therapeutic effect can be changed or modified by its being taken either hot or cold. In the case of those waters which are alkaline and contain a considerable quantity of bicarbonate of sodium or other saline materials of a closely related character, we find that they are particularly useful in the treatment of gouty and rheumatic affections; that waters containing sulphur in its various forms are useful in many acneiform and scaly eruptions of the skin and in catarrhal states of the alimentary and other mucous membranes; that ferruginous or iron waters are valuable in cases of anæmia, while those waters which contain as their chief ingredients sulphate of magnesium and sulphate of sodium are of value in chronic dyspepsia, gastro-intestinal catarrh with constipation, and for the relief of hemorrhoids. The saline waters with purgative properties are increased in their efficacy, as a rule, if they are taken hot. Some instances of diarrhœa can be much benefited by the use of waters containing iron and alum. So, too, patients suffering from catarrh of the bile-ducts, or from gallstone colic, are often benefited by a prolonged course of alkaline or purgative saline waters.

In cases of irritability of the bladder depending upon excessive acidity of the urine, which often is scanty in quantity, the alkaline waters are of great value, since they not only cause a free flow of urine, thereby diluting it, and carrying out of the bladder various excretory matters, but also render the urine alkaline, so that the bladder is no longer irritated by acid substances. When an excess of phosphates is present and the urine is very alkaline, the use of waters containing sodium bicarbonate is inadvisable. The most celebrated springs containing bicarbonate of sodium are those of Vichy, in France; while the best known mildly alkaline springs in North America are at Saratoga.

The waters of most of the thermal springs do not possess any therapeutic properties apart from their heat. This factor is, however, an important one in aiding in the absorption and elimination of drugs and poisons.

For a description of the various medicinal springs of North America and Europe, and their therapeutic application, see Crook's *Mineral Waters of the United States*, and Hayem's *Physical and Natural Therapeutics.*

ARACEÆ.—The Arum Family.

Genera more than 100, species nearly 1000, mostly tropical, many marsh or water plants, others (which is much the same thing in the humid tropics) at least partially epiphytic. On account of their starch, the rhizomes and bulbs of many species are used as foods or the starches are extracted. Even those which are poisonous may be thus employed, since cooking usually destroys their toxicity. Mere drying partially destroys the toxicity and acridity. Hydrocyanic acid, which exists uncombined, can often be distilled, but the chief toxicity is not due to this. The acridity is partly due to soluble substances and partly to the mechanical effect of needle-shaped crystals. Tannin is not common or abundant.

The most important edible product is the corm of *Calocasia Calocasia* (L.) Lyons (*Arum C.* L.; *C. antiquorum* Schott; *C. esculenta* Schott; *Caladium e.* Vent.; *Arum e.* L.), the *Taro*, *Kalo*, *Cocco*, *Cocoe*, *Tanya*, *Eddoes*, *Eddas*, *Edders*, *Yo-tao*, *Sato-imo*, *Oto*, or *Kalkas*, which is one of the most largely used of tropical foods. Other species of this genus are similarly used, as are *Alocasia Indica* Schott, *A. mucronata* Schott, *Caladium violaceum* Desf., *Xanthosoma edule* Schott, *X. sagittæfolium* Schott, *Amorphophallus giganteus* Bl., *A. sativus* Bl., and *Schismatiglottis calyptrata* Zoll. et Moc. *Monstera deliciosa* yields an edible fruit.

Irritant or stimulant members of the family are so numerous that only a few of the better known are here named.

The juice of the root of *Dieffenbachia Seguina* Schott, of the West Indies, is very acrid and poisonous; its tincture is employed in *pruritus vulvæ*. The rhizome of *Monstera perpusa* Schott is used as a rubefacient and powerful diuretic. *Lagenandra toxicaria* Dalz., or *Vutsusap*, is very poisonous. We have seen the rhizome of a Bolivian species of *Anthurium* in use as a poison by the Indians. The roots and seeds of *Orontium aquaticum* L., the *Golden club*, or *Tawkin*, as well as the seeds of *Peltandra*, the *Arrow-head*, and of *Skunk's cabbage*, all of the United States, are highly acrid and used as antispasmodics, though edible when thoroughly cooked. As antispasmodics, are also used the leaves of *Syngonium Vellozianum* Schott, the *Espirito Santo* (for asthma), *Richardia Africana* Kth. (flatulence), *Homalomena aromaticum* Schott (aphrodisiac), *H. cordata* Schott, *H. rubescens* Kth., *H. alba* Hassk., the latter also a starch-yielder, and various species of the genus *Pothos*. Various species of the genus *Philodendron* have been used as counter-irritants, one of them especially in orchitis.

Anthelmintics are less numerous. They include several species of *Caladium*, the seed of *Philodendron bipinnatifidum* Schott, *Montrichardia aculeata* Crueg., *Scindapsus officinalis* Schott, the *Gaya-pipal*, *Thora-pimpali*, *Vashira*, etc., of India, *Epipremum mirabile* Schott, and *Rhaphidophora lacera* Hassk., one of the ingredients of the *Tonga* of the Fiji Islanders. It is said to contain a volatile alkaloid, *tonghine*.

Synantheris silvaticus Schott, the *Jangli-soorum*, *Madan-must*, or *Kunmar-kas*, is used as a bitter. *Spathyphyllum Humboltii* Schott, of South America, is used as a vanilla substitute.

ARALIA.

A genus of some 25 species of the family *Araliaceæ*, and sharing in its generally aromatic properties. A number of species have enjoyed an extensive use as drugs, and the two following are worthy of special notice:

ARALIA NUDICAULIS L.—*False or Wild sarsaparilla, Small spikenard, Wild liquorice*, E.; *Nackte Aralienwurzel*, G.; *Aralie à tige nue, Petit nard*, Fr.—It is a perennial plant indigeneous to Canada and the United States, where it grows in rich and rocky woodlands as far south as Carolina and Tennessee, and west to the Rocky Mountains. The rhizome sends up a single petiole about 30 Cm. (12 In.) long, and 3-parted at the summit, each division bearing 5 ovate or oval, serrate, and subsessile leaflets. The scape is divided into 3 to 5 peduncles, each bearing a globose loose umbel of many greenish flowers. The rhizome, which is the part employed, is several feet long, horizontal, with some slender branches, and sparingly beset with a few roots. The internodes are indistinct and the undeveloped buds alternate. The dry rhizome is about 6 Mm. (¼ In.) in diameter; the few scape-scars are shallowly cup-shaped, and approximate at the upper annulated end of the branches; the bark is longitudinally wrinkled, of a somewhat glossy pale brownish-gray color externally, the corky layer being easily removed from the white inner bark, which does not firmly adhere to the cylindrical wood. The latter is about 3 Mm. (⅛ In.) in diameter, of a yellowish color, and encloses a spongy white amylaceous pith. The rhizome breaks with a short fracture, and is somewhat aromatic, has a mawkish taste, and contains a little volatile oil, resin, sugar, pectin, and starch.

ARALIA RACEMOSA L.—*American spikenard, Spignet, Pettymorrel*, E.; *Amerikanische Narde*, G.; *Nard américain*, Fr.—This plant grows in similar localities as the preceding, but is found southward to Georgia. It has an herbaceous stem about 1 M. (40 In.) high, and ternately and quinately divided leaves with ovate or heart-ovate doubly serrate leaflets. The flowers are in small umbels arranged in ample branching racemes. The rhizome is oblique, 10 to 15 Cm. (4–6 In.) long, and half as thick; the nodes are approximate, and the stem-scars prominent, about 25 to 38 Mm. (1–1½ In.) in diameter, the older ones deeply concave. The roots are numerous, from 50 to 75 Cm. (20–30 In.) long, about 25 Mm. (1 In.) thick near the rhizome, and little branched below. It has a stronger aromatic odor and taste than the preceding, and has similar constituents.

Pharmaceutical Preparation.—FLUIDEXTRACT OF ARALIA, N. F.

The California spikenard, *Aralia Californica* Watson, resembles *Aralia racemosa*, but the plant and the root are much larger.

ARALIA EDULIS Siebold is indigenous to Japan and cultivated there. In appearance and size the rhizome resembles Solomon's seal, but the circular stem-scars are somewhat spirally arranged, about ½ inch apart, and the wood is in radiating bundles.

ARALIA PAPYRIFERA Hook., indigenous to Formosa, contains a thick white pith, which, cut into thin layers, constitutes part of the so-called Chinese *rice-paper*.

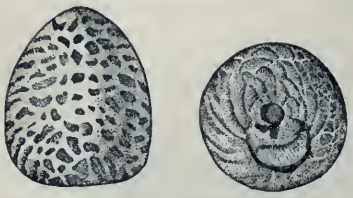
Action and Uses.—*Aralia nudicaulis* and *Aralia racemosa* are employed by the laity as stimulants, diaphoretics, and alteratives. An infusion or decoction (℥j to Oj) is said to possess value in the treatment of syphilis, chronic rheumatism, and chronic cutaneous affections. When locally applied, the decoction is said to be valuable also as a stimulant to sluggish ulcers. California spikenard may be employed for the same purposes as the other varieties.

The *Ariliaceæ*, or *Ivy Family*, is in all ways closely related to the *Umbelliferæ*, comprising more than 50 genera and nearly 400 species, distributed through subtropical and warm-temperate regions, especially in the South American Andes, southern and southeastern Asia and the adjacent islands; in foliage and frequently in inflorescence-habits, highly ornamental, though the individual flowers are not showy; other economic properties, except medicinal, unimportant. Chinese rice-paper is made from *Tetrapanax Papyrifer* (Hook.) K. Koch and some other species. The foliage of a few species is used in salads and as potherbs. Volatile oils similar to those of the *Umbelliferæ* impart aromatic properties to most of the species, especially of *Aralia* and *Panax* (which see), which have rendered them famous in unlearned medical practice, though little esteemed in scientific circles. *Fatsia payrifera* (Hook.) B. et H., *T'ung oh-muh* or *T'ung-ts'au* of China, *Dendropanax arboreum* Dec. et Pl., of tropical America, *Didymopanax Morototoni* Decne, of South America, and *Brassiopsis Haimla* Seem (*Hedera scandens* DC.), may be specially mentioned in this connection. The wood of *Bolyscias nodosa* Forst. (*Aralia n.* Bl., *Hedera n.* Hassk.), of the East Indies, is used as a fish poison. *Hedera Helix* L., the common ivy of Europe, has an ancient medical history. All parts of the plant have been used. The leaves possess mild aromatic properties, differing little from others of the class. Besides *Carotin*, contained also in carrot, they contain the glucoside *helixin* ($C_{32}H_{52}O_{10} + 2H_2O$). The fruit is reputed poisonous, but there appears no evidence that this is true.

ARECA.—Areca-nut.

Semen Arecae.—Betel-nut, E.; *Arekanuss, Betelnuss*, G.; *Noix d'arec*, Fr.
The seed of *Areca Catechu* L. (Fam. *Palmaceæ*), a handsome tall palm, native and very largely cultivated in the East Indies.

FIG. 33.



Areca: lateral and basal surfaces (Nat.).

Description.—1 inch (25 Mm.) or less in length, bluntly conical or strawberry-shaped, the depressed base bearing short fibrous remains of the pericarp; light gray-brown with numerous broad, interrupted reddish veins winding spirally from base to apex; internally ruminated with similar veins, the small embryo near the base; heavy, hard, faintly aromatic, astringent and slightly acrid. The inner layers of the testa and the internal veins contain tannin, and the principal alkaloid, *arecoline*, is contained in or near the latter.

By imperfect drying, a fungous growth is sometimes caused to grow within the tissues.

The areca fruit is a 1-seeded drupe, somewhat resembling a small apple in form and size, the surface orange-yellow, smooth and shining, and the thick mesocarp tough-fibrous. The fruits are husked, boiled, and dried to prepare them for the market. So prepared, they are a highly prized and largely used masticatory in the Orient. Three varieties of the product are recognized; *Chilkin*, made from the unripe, *Betta*, from the moderately ripe, and *Gotu*, from the dead-ripe, fruits.

The leaves of the tree yield a volatile oil.

Constituents.—Johns has found 4 alkaloids. *Arecoline* ($C_8H_{13}NO_2$), 0.07–0.1 per cent., is a colorless oily liquid, chemically resembling *pelletierine* and miscible in all proportions with water, alcohol, ether, and chloroform. Its salts are crystalline and hygroscopic, except the hydrobromide, which is non-hygroscopic. *Arecaine* ($C_7H_{11}NO_2.H_2O$), 0.1 per cent., is a betaine-like body, in colorless crystals, soluble in water, scarcely so in alcohol, chloroform, or ether, and forming crystalline salts of acid reaction. *Arecaidine* ($C_7H_{11}NO_2.H_2O$) is an isomer of arecaine, crystallizing in colorless plates and soluble in water and dilute alcohol. *Guvacine* ($C_6H_9NO_2$) is soluble in water and dilute alcohol, forms small lustrous scales, and yields soluble salts of acid reaction. Arecoline is methyl-arecaidine, and is easily converted into arecaidine and the latter into arecoline. Areca yields also 14 per cent. of tannic acid resembling catechutannic acid, gallic acid, 14 per cent. of fat and oil, gum, and areca-red (a dye). It contains no catechin.

Of the 4 alkaloids found in areca-nut, only arecoline is said to be of importance; the other 3 being considered as possessing no medicinal value. For the purpose of extracting the alkaloids, coarsely powdered areca-nut is exhausted by means of cold water acidulated with sulphuric acid, the infusion being concentrated and precipitated with potassium-bismuth iodide. The resulting crystalline red precipitate is thoroughly washed and boiled with a mixture of barium carbonate and water, which causes the alkaloids to go into solution. After concentration of the solution, barium hydroxide is added in excess, and the mixture immediately shaken out with ether, which takes up the arecoline, but leaves the other alkaloids in the aqueous liquid. The German Pharmacopœia recognizes arecoline hydrobromide.

Arecolinum Hydrobromicum, P. G.—*Arecolinæ Hydrobromidum.—Arecoline hydrobromide*, E.; *Arekolinhydrobromid, Bromwasserstoffsaueres Arekolin*, G. Formula, $C_8H_{13}NO_2HBr$. Molecular weight, 234.33.—This salt occurs in the form of colorless anhydrous needle-shaped prisms, which are crystallized from a hot alcoholic solution. It is readily soluble in water and in alcohol, but difficultly soluble in ether and chloroform. The crystals melt at 167°–168° C. (332.6°–334° F.). An aqueous 5 per cent. solution is not precipitated by potassium hydroxide solution, nor by solutions of platinum chloride, mercuric chloride, or tannic acid, but addition of iodine solution, bromine water, and silver nitrate solution causes respectively a brown, yellow, and pale-yellow precipitate.

Action and Uses.—Areca-nut has been largely employed in its native country for the expulsion of tapeworms, and its efficacy has been confirmed by many practitioners. The freshly grated nut may also be used for the removal of round worms. Its alkaloid, arecoline, slows the pulse, and purges by notably increasing intestinal peristalsis. In over-

dose it occasionally produces tetanic convulsions. Poisonous amounts of arecoline cause respiratory and cardiac depression, and prove fatal through arrest of the respiratory function.

The dose of the powdered drug is from 2 to 4 drachms (8–16 Gm.), usually administered in syrup.

ARGENTI CYANIDUM, *U. S.*—Silver Cyanide.

Argentum cyanatum.—Cyanure d'argent, Fr.; *Silbercyanid, Cyansilber.*

Formula, AgCN. Molecular weight, 132.96.

It should not contain less than 99.9 per cent. of pure silver cyanide corresponding to 80.48 per cent. of metallic silver, and should be kept in dark amber-colored bottles, protected from light.—U. S.

Preparation.—Silver cyanide may be prepared by distilling hydrocyanic acid from a retort by the action of sulphuric acid on potassium ferrocyanide, into a receiver containing a solution of silver nitrate in water. The precipitated silver cyanide is filtered out, washed, and dried. The reaction occurring is explained by the following equation: $HCN + AgNO_3 = AgCN + HNO_3$.

Silver cyanide may also be conveniently prepared by adding a solution of silver nitrate to a solution of pure potassium cyanide as long as a precipitate continues to be formed, and then filtering and washing the precipitate well with distilled water. When silver nitrate solution is first added, no precipitation occurs, owing to the formation of a soluble compound, $KAg(CN)_2$; but this is decomposed by further addition of the silver solution, and silver cyanide is then precipitated. About 17 Gm. of silver nitrate will require 6.5 Gm. of potassium cyanide, producing about 13.3 Gm. of silver cyanide, the two reactions taking place being as follows: (1) $2KCN + AgNO_3 = KAg(CN)_2 + KNO_3$; (2) $KAg(CN)_2 + AgNO_3 = 2AgCN + KNO_3$.

Properties.—Silver cyanide is a white powder, without odor or taste, permanent in dry air, but gradually turning brown on exposure to light. It is insoluble in water, alcohol, or cold nitric acid, but soluble in boiling nitric acid with evolution of hydrocyanic acid; also soluble in ammonia-water, sodium thiosulphate test-solution, and potassium cyanide test-solution. When heated in a porcelain crucible the salt fuses, gives off cyanogen gas, and, on ignition, leaves a residue of metallic silver amounting to 80.48 per cent. of its original weight.—U. S.

Action and Uses.—Silver cyanide is rarely employed in medicine, but is used in pharmacy for the preparation of diluted hydrocyanic acid.

ARGENTI NITRAS, *U. S., Br.*—Silver Nitrate.

Argentum nitricum crystallisatum, P. G.—*Nitrate (Azotate) d'argent, Nitre lunaire*, Fr.; *Silbernitrat, Salpetersaures Silberoxyd, Silbersalpeter*, G.; *Nitrato di plata*, Sp.; *Nitrato di argento crystallizzato*, F. It.

Formula, $AgNO_3$. Melecular weight, 168.69.

It should contain not less than 99.9 per cent. of pure silver nitrate, and should be kept in dark amber-colored vials, protected from light.—U. S.

Preparation.—Silver as free as possible from other metals is dissolved in pure nitric acid diluted with about an equal bulk of water. The chemical change is represented thus: $3Ag + 4HNO_3 = 3AgNO_3 + NO + 2H_2O$. The colorless nitric oxide NO, on coming in contact with oxygen of the air, combines with it; thus, $NO + O = NO_2$, forming reddish fumes of nitrogen tetroxide. The solution of silver nitrate is evaporated to the crystallizing-point and set aside in a cool place. The crystals are drained off in a funnel and the mother-liquor further evaporated and set aside to crystallize. Contact of organic substances with silver nitrate should be avoided.

If pure silver and pure nitric acid are taken, the crystals of silver nitrate need no purification, but if small quantities of copper and other metals are present purification is necessary. This may be done by recrystallization, or the solution may be evaporated to dryness, and the salt carefully heated in a porcelain dish until it is in quiet fusion and colored acid fumes cease to come off. The nitrates of copper and other metals are decomposed into their oxides and the fused mass acquires a more or less dark-gray color. The cooled mass is digested with water, the silver nitrate passes into solution while the

impurities are left behind, being insoluble. The solution is evaporated to crystallization with addition of a little nitric acid.

If considerable copper is present in the silver, it is advisable to purify the silver by one of the methods given elsewhere (see Argentum). None of the pharmacopœias give an official method for preparing silver nitrate.

When silver nitrate is required in sticks or pencils, it is fused in a porcelain vessel and stirred until uniform, and then poured into silver- or gold-lined iron or steel moulds, where it hardens. Care must be taken to avoid overheating and contact with organic substances and dust, else the sticks will have a gray appearance and turn darker in the light. Although pure silver nitrate is unaffected by light, it is well to preserve it in dark bottles with glass stoppers. The fused nitrate is known as *Lapis infernalis* and *Höllenstein* (G.).

Properties.—Silver nitrate exists in colorless shining tabular crystals of the rhombic system, which are inodorous and have a caustic and strongly metallic taste and a neutral reaction. It is soluble at 25° C. (77° F.) in 0.54 part of water and in 24 parts of alcohol (U. S.); in 0.6 part of water and in .10 parts of alcohol, specific gravity 0.832 (P. G.); also in 0.1 part of boiling water and in 5 parts of boiling alcohol (U. S.). It is likewise, though less freely, soluble in ordinary ether, but nearly insoluble in absolute ether, freely soluble in diluted, but sparingly soluble in strong nitric acid. It melts at 200° C. (392° F.) to a faintly yellow liquid, and on cooling congeals to a white crystalline mass; at a higher temperature nitrous vapors are given off, leaving silver oxide and nitrate; heated to a dull-red heat, metallic silver is left. The crystals and the aqueous solution are permanent in the air and light, except in the presence of organic matter, whereby they acquire a dark color. The alcoholic solution when exposed to the light is gradually reduced, silver being separated. Hydrochloric acid produces in the solution a white curdy precipitate of silver chloride, which is insoluble in dilute nitric acid, but dissolves readily in ammonia. Stains produced by silver nitrate upon the skin are removed by rubbing them with a strong solution of potassium cyanide, or by moistening them first with a solution of iodine and afterward with sodium thiosulphate. The solution of silver nitrate acidulated with nitric acid and heated with alcohol produces the violently explosive compound known as *fulminating silver*. Silver nitrate contains no water of crystallization.

Tests.—1 Gm. of silver nitrate yields 0.843 Gm. of chloride.—Br. The salt should yield with ammonia a clear and colorless solution (absence of copper, lead, etc.), and its aqueous solution, when precipitated by an excess of hydrochloric acid, should yield a filtrate which when evaporated leaves no residue (absence of other salts). A 10 per cent. aqueous solution, mixed with 4 times its volume of diluted sulphuric acid and heated to boiling, should not become turbid.—U. S. This test indicates the absence of lead, the sulphate of which is insoluble, while silver sulphate is soluble in 68.6 parts of boiling water. If 0.5 Gm. of silver nitrate, dissolved in 10 Cc. of water, be mixed with 30 Cc. of tenth-normal sodium chloride solution and 3 drops of potassium chromate test-solution, not more than 0.4 Cc. of tenth-normal silver nitrate solution should be required to impart a permanent red color.—U. S. Each Cc. of sodium chloride solution corresponds to 0.016869 Gm. of $AgNO_3$, hence 29.6 (30–0.4) Cc. corresponds to 0.4993 Gm., or 99.86 per cent.—U. S.

Action and Uses.—The pure crystals of silver nitrate are usually employed in internal medicine; solutions of the crystals as well as of the moulded nitrate of silver and of mitigated caustic are frequently employed locally. The two last forms are also used in the solid stick for escharotic purposes. The action and uses of all three are practically the same.

When nitrate of silver is locally applied either to the skin or mucous membrane, it produces burning pain with superficial destruction of the tissue. A white eschar is at first formed, which in a short time becomes of a brown or black color, due to the oxidation of the silver. The albumin of the tissue is coagulated, thereby forming a barrier to the silver salt, and for this reason deep destruction of the part is prevented. When taken internally, its action upon the various vital functions of the organism is not thoroughly understood, but its effect upon respiration and circulation bears no relation to its use in practical medicine. When administered internally in overdose, silver nitrate rapidly produces a violent gastro-enteritis attended with excessive abdominal pain, vomiting, and purging. The vomitus is frequently white and curdy, but may be brownish

in color. The lips are stained first white, and later brown. The face is pinched and covered with perspiration. Occasionally delirium, coma, and epileptiform convulsions are present. Death results either from collapse occasioned by the severe pain or by paralysis of the respiratory center accompanied by exudation of mucus into the bronchial tubes.

The treatment of acute poisoning with nitrate of silver consists in the employment of sodium chloride as the chemical antidote. The application of external warmth to maintain bodily heat, and the administration of opium or morphine and bland draughts, such as milk or emulsions of bland oils, to relieve pain and irritation, should be resorted to. Large draughts of water or soapsuds may be given to dilute the poison. Stimulants such as strychnine, alcohol, and atropine should be employed as necessity demands.

Chronic silver-poisoning, or "argyria," is a condition following the continued administration of silver nitrate, and is characterized especially by the peculiar slate-blue color of the skin and the livid, cadaveric appearance of the individual. This results from a deposition of the salt in the tissues, and is usually first seen in the conjunctiva or the inner surface of the lips. As a rule, argyria is not curable so far as restoration of normal color is concerned. It may be treated by the administration of potassium iodide to aid in the elimination of the drug.

Internally when combined with extract of hyoscyamus or opium silver nitrate is the best drug to employ in the treatment of gastric ulcer. Its administration is also beneficial in treating subacute gastritis, chronic gastric catarrh, chronic diarrhœa, and catarrhal inflammation of the gall-ducts. The drug has been employed in the treatment of intestinal ulcerations attending enteric fever, and in many cases its success has been apparent. In a few instances it has cured tabes dorsalis and anterior spinal sclerosis, but in most cases it has failed to influence the progress of these diseases. Epilepsy was formerly treated by its administration, but this practice is now largely abandoned. Acute and chronic dysentery and ulcerations of the large intestine may be cured by irrigation with a solution of silver nitrate. The bowel should first be emptied, and thoroughly washed out with warm water. If the ulceration is high up in the bowel, 1 drachm (4 Gm.) of the salt in 3 pints (1440 Cc.) of warm water should be injected; if in the rectum, 3 to 5 grains (0.20–0.30 Gm.) in 4 ounces (120 Cc.) of warm water may be used. Should this irrigation prove very painful, relief may be obtained by a second injection of salt solution (℈j to pint j). A 5 per cent. solution has been recommended to prevent the spread of erysipelatous inflammation and the pitting of smallpox. Orchitis and epididymitis in their incipiency may be aborted by painting the scrotum with a 20 per cent. solution of the drug in water. Inflammation of the pharynx and larynx is frequently relieved by the application of a 1.5 per cent. solution, and a spray containing 2 grains (0.12 Gm.) to the ounce (30 Cc.) has been employed in the treatment of laryngeal tuberculosis and whooping-cough. A solution containing $\frac{1}{8}$ of 1 per cent. of the salt is useful as an injection in chronic gonorrhœa, and one containing 1 part of the salt in 5000 parts of water is frequently employed in the treatment of cystitis. Gonorrhœal ophthalmia in all its stages is benefited by the application of silver nitrate.

Leucorrhœa resulting from cervical congestion or uterine ulceration may be cured by the application of the solid stick, and exuberant granulations, venereal excrescences, warts, and chancroids may be destroyed by its use.

A strong solution painted around the edges of the inflamed zone has been used to abort boils, felons, and bedsores. Strong solutions were formerly employed in the abortive treatment of specific urethritis, but this treatment is now practically abandoned, as it frequently increases the intensity of the disease, and often fails to cure.

The dose of silver nitrate is from $\frac{1}{8}$ to $\frac{1}{4}$ of a grain (0.001–0.0015 Gm.) in pill form. When employed for ulcer of the stomach or other gastric disease, it should be administered upon an empty stomach.

ARGENTI NITRAS FUSUS, *U. S.*—Molded Silver Nitrate.

Argenti nitras induratus, Br.—*Toughened caustic*, E.; *Azotate d'argent fondu*, Fr.; *Gehärteter Höllenstein*, G.

It should contain not less than 94.8 per cent. of pure silver nitrate.—U. S.

Preparation.—Silver nitrate, 100 Gm.; hydrochloric acid, 4 Gm. To the silver nitrate contained in a porcelain capsule add the hydrochloric acid, and melt the mixture at as low a temperature as possible. Stir well, and pour the melted mass into suitable

moulds. Keep the product in dark, amber-colored vials, protected from light.—U. S. Fuse and thoroughly mix 95 Gm. of silver nitrate and 5 Gm. of potassium nitrate, and pour into moulds.—Br.

The reasons for the cautious application of heat when fusing silver nitrate have been pointed out above (see Argenti Nitras). The salt being decomposed by nearly all the metals when heated with them, capsules of platinum or of the best porcelain are the only vessels suitable for this operation. When fused, it has the appearance of a colorless, transparent, oily liquid, and is then ready to be poured into the moulds, which should be faced with pure silver. Brass moulds are sometimes used, but they are liable to contaminate the product with copper. Steel or porcelain moulds may be used after they have been rubbed with powdered French chalk, which prevents the fused salt from adhering to the mould. If the moulds have been previously warmed to about 40° or 50° C. (104° or 122° F.), the fused mass will not congeal too rapidly. Oiling the moulds should be avoided, lest a reduction of the salt should take place.

Properties.—Moulded *pure* silver nitrate is met with in nearly colorless thin cylinders or pointed cones, which when broken show a crystalline texture upon the fractured surface; in solubility, chemical behavior, and composition it agrees with the crystallized nitrate. It is not affected by light unless it has been partly reduced by too high a heat to silver nitrite or been in contact with organic matter; wrapping the sticks in paper or handling them with the fingers should therefore be avoided. The pencils are rather brittle, but the addition of a little silver chloride, as proposed by Dr. Squibb (1858), renders the sticks more opaque and tough. This is now recognized by the U. S. P. Oxide or metallic silver in very fine division is occasionally present, either in consequence of too high a heat having been employed or because the sticks have been in contact with organic matter; it is left as a black powder on treating the sticks with distilled water. If 0.50 Gm. of molded silver nitrate, dissolved as completely as possible in 10 Cc. of water, be mixed with 30 Cc. of decinormal sodium chloride solution, and then a few drops of potassium chromate test-solution added, not more than 1 to 9 Cc. of decinormal silver nitrate solution should be required to impart to the liquid a permanent red color (corresponding to 94.8 per cent. of pure silver nitrate).—U. S. 1 Gm. should yield 0.8 Gm. of silver chloride.—Br.

Action and Uses.—Molded nitrate of silver is rarely employed in solution, but it may be locally used instead of the pure crystals. It is never given internally, because of the impurities which it frequently contains. Lunar caustic is employed for the removal of venereal warts, excessive granulations, and diphtheritic exudations. Its solution is employed for the same purpose and in the same strength as that made from the pure crystals (see Argenti Nitras).

ARGENTI NITRAS MITIGATUS, *U. S., Br.*—Mitigated Silver Nitrate.

Argenti nitras dilutus, U. S., 1890; *Argentum nitricum cum kalio nitrico*, P. G.; *Lapis infernalis nitratus.—Diluted silver nitrate, Mitigated caustic, Nitrate of silver and potassium*, E.; *Azotate d'argent mitigé, Pierre infernale diluée*, Fr.; *Salpeterhaltiges Silbernitrat, Salpeterhaltiger Höllenstein*, G.

It should contain not less than 33.3 per cent. of pure silver nitrate.—U. S.

Preparation.—Silver nitrate, 30 Gm.; potassium nitrate, 60 Gm. Melt the salts together in a porcelain crucible at as low a temperature as possible, stirring the melted mass well until it flows smoothly. Then cast it in suitable moulds. Keep the product in dark, amber-colored vials, protected from light.—U. S.

Silver nitrate, 1 part; potassium nitrate, 2 parts.—P. G., Br.

Properties.—A white, hard solid, generally in the form of pencils or cones, of a finely granular fracture, becoming gray or grayish-black on exposure to light in presence of organic matter; odorless, having a caustic metallic taste and a neutral reaction. Each of its constituents retains the solubility in water and in alcohol, mentioned respectively under Argenti Nitras and Potassii Nitras.—U. S. The pencils are less fragile and more opaque than those made of pure silver nitrate. They will contain silver nitrite, and blacken on exposure to light if the salts have been melted at too high a heat. If made with sodium nitrate, they become superficially moist in a damp atmosphere.

Tests.—An aqueous solution of mitigated silver nitrate yields, with a slight excess of hydrochloric acid, a white precipitate, which is readily soluble in ammonia-water.

The filtrate from the precipitate, when evaporated to dryness, yields a white residue which is completely soluble in water, and this solution affords a yellow crystalline precipitate with platinic chloride test-solution, and a white crystalline precipitate with sodium bitartrate test-solution. If to an aqueous solution of mitigated silver nitrate a slight excess of ammonia-water be added, it should neither assume a blue color (absence of copper) nor show turbidity (absence of lead and bismuth). If 1 Gm. of mitigated silver nitrate, dissolved in 10 Cc. of water, be mixed with 20 Cc. of tenth-normal sodium chloride solution, and then a few drops of potassium chromate solution added, not more than 0.3 Cc. of tenth-normal silver nitrate solution should be required to impart to the liquid a permanent red color (corresponding to at least 33.23 per cent. of pure silver nitrate).—U. S. 3 Gm. should yield 0.843 Gm. of AgCl.—Br.

Action and Uses.—This is merely a mitigated form of molded silver nitrate, and may sometimes be found convenient when a slight caustic action is intended.

ARGENTI OXIDUM, *U. S., Br.*—Silver Oxide.

Argentum oxydatum.—Argentic oxide, E.; *Oxyde d'argent,* Fr.; *Silberoxyd,* G.

Formula, Ag_2O. Molecular weight, 230.12.

Silver oxide should be kept in dark amber-colored vials, protected from light. It should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia. It should contain 99.8 per cent. of pure oxide, corresponding to not less than 92.9 per cent. of pure metallic silver.—U. S.

Preparation.—It was formerly prepared by precipitating silver nitrate by potassium hydroxide (U. S. 1870). The Br. P. directs the use of lime water. The reaction is $2AgNO_3 + 2KOH = 2KNO_3 + H_2O + Ag_2O$. The oxide is filtered, washed, and dried at a temperature not above 100° C. (212° F.). The caustic alkali should be free from chloride and carbonate, to avoid formation of silver chloride and carbonate along with the oxide. It may also be prepared by boiling silver chloride (moist) with strong potassium hydroxide solution, until a portion of the sediment is completely soluble in nitric acid.

Properties.—Argentic oxide is an olive-brown or blackish powder, soluble in 3000 parts of water with alkaline reaction. When moist it attracts carbon dioxide. It is reduced by the action of light, also decomposed at 250°–300° C. (482°–572° F.) into silver and oxygen; it should therefore be well dried and kept in dark, amber-colored bottles, protected from light. Freshly prepared silver oxide is wholly soluble in ammonia water, after drying and keeping only partly, leaving a black powder, *Berthollet's fulminating silver,* and the solution depositing black crystals of the same compound, which is violently explosive. The oxide, moistened with creosote or when mixed with tannin, amorphous phosphorus, precipitated sulphur, the sulphides of arsenic and antimony, or with other readily oxidizable or combustible substances, renders these spontaneously inflammable.

Tests.—Silver oxide should be completely dissolved without effervescence in dilute nitric acid (absence of carbonate or chloride), and the colorless solution should respond to the reactions and tests stated under Argenti Nitras. 0.5 Gm. of the oxide when ignited in a porcelain crucible should yield not less than 0.464 Gm. (or 92.9 per cent.) of metallic silver.—U. S. 1 Gm. should yield 1.237 Gm. of AgCl when dissolved in nitric acid and precipitated with hydrochloric acid.—Br.

Action and Uses.—Silver oxide may be employed in internal medicine for the same conditions in which silver nitrate is used, but because of its slight solubility is probably of less benefit than the latter salt (see Argenti Nitras). For local application solutions of silver nitrate are always to be employed.

Silver oxide is given in doses of from ½ to 2 grains (0.03–0.12 Gm.), 3 times daily.

ARGENTUM.—Silver.

Argentum purificatum.—Refined silver, E.; *Argent, Argent raffiné,* Fr.; *Silber, Raffinirtes Silber,* G.; *Argento,* F. It.

Symbol, Ag. Atomicity univalent. Atomic weight, 107.12.

Origin.—This metal was known and in use in the earliest historic period, and was

called *Luna* or *Diana* by the alchemists. It is found free and in combination with various metals, and with sulphur, chlorine, bromine, iodine, etc., the richest silver ores being in the western United States, Mexico, Peru, Norway, Russia, Germany, and Spain.

Preparation.—The extraction of the metal is effected by different processes, the details varying considerably with the richness and the composition of the ore. The process of *amalgamation* is based upon the formation of an alloy between metallic mercury and silver. The finely powdered ore is intimately mixed with sodium chloride and then roasted, when the mass contains, besides metallic silver, its chloride, the latter being converted to the metallic state by agitation in a revolving cylinder with water and iron. Mercury is now added and the agitation continued, when the silver, gold, and copper unite with the mercury, the amalgam being obtained by subsidence and washing, and afterward separated into a liquid and a solid portion by subjecting it to pressure in strong linen or leather bags. By distilling the solid portion, the mercury is volatilized and recovered, while the silver remains, containing copper and gold.

In the process of *cupellation* galena (lead sulphide) containing silver is first reduced and the metallic lead allowed to cool slowly, when almost pure lead crystallizes, and is removed by means of a ladle or by carefully draining off the liquid portion, which is rich in silver. This is exposed to a red heat, and air directed upon it by means of a blast, whereby the lead is oxidized and the litharge blown off, leaving silver containing some lead. This is now transferred to a dish made of bone-ash and heated to redness; the plumbic oxide formed is absorbed by the porous vessel, and finally almost chemically pure silver is left.

By the careful roasting of the ore containing the metals as sulphides these are converted into sulphates, which are treated with hot water; from this solution the silver is precipitated by metallic copper, the latter being subsequently recovered by precipitation with iron.

Many modifications of these and other processes are employed, the silver obtained on the large scale always retaining a small portion of other metals.

Chemically pure silver is obtained in various ways from the chloride, which is readily prepared free from other chlorides by precipitating the solution in nitric acid with hydrochloric acid and washing it thoroughly with water. The silver chloride is then reduced by boiling it with glucose and sodium carbonate; the powdered silver thus obtained is well washed with acetic acid and water and then fused. Or the chloride is mixed with acidulated water and a rod of zinc introduced, the silver being afterward fused with borax and saltpeter. Or a mixture of the chloride with sodium and potassium carbonate is heated, whereby silver, alkali chlorides, carbon dioxide, and oxygen are formed: $2AgCl + KNaCO_3$ yields $Ag_2 + KCl + NaCl + CO_2 + O$.

For the technical preparation of pure silver, only two processes, in the main, are employed at present, namely, the sulphuric acid and the electrolytic method. In the former, the granulated silver is boiled with concentrated sulphuric acid, and the silver sulphate brought into solution with much hot water. From this solution the silver is precipitated by iron, the fine powder is pressed into bricks and melted in crucibles. In the electrolytic process the silver in the form of plates is hung as the anode in a bath of silver nitrate and copper nitrate, from which it is carried by the electric current to the cathode, which is made of thin silver plates, where it deposits in large pure crystals. By washing and drying these, they are ready for the market.

Properties.—Silver is a brilliant white metal, very ductile and malleable, having the specific gravity 10.47 when obtained by fusion; the pressed and the distilled silver have a density of 10.57. It may be drawn into very fine wire and beaten into very thin *silver-leaf, Argentum foliatum* (P. G.). It melts at about 1000° C. (1832° F.), absorbs oxygen, which on cooling is again given off, but it does not oxidize in contact with the air at a red or white heat, and distils at the heat of the oxyhydrogen flame. It is tarnished superficially by the hydrogen sulphide contained in the atmosphere. It dissolves completely in diluted nitric acid and hot concentrated sulphuric acid, but is insoluble in hydrochloric acid and dilute sulphuric acid. Pure silver is too soft for coins, utensils, etc., and therefore copper is added to it to make it harder and more durable. Silver is unaffected by fused alkalies or alkali nitrates, and hence silver crucibles and spatulas are used in the laboratory for such fusions. Silver forms a greater number of insoluble or difficultly soluble salts than any other metal. The nitrate is the most important silver salt.

Various allotropic modifications of metallic silver have been obtained by treating solutions of silver salts with different reducing agents; some of these have been found soluble in water, and nearly all of them can be reduced to powder by moderate trituration. The particular allotropic form appears to depend upon the reducing agent employed and the conditions under which reduction takes place; thus blue, lilac, green, gold-colored, and reddish-brown silver have been obtained. The usual methods followed are (1) reduction of silver citrate or tartrate by ferrous citrate or tartrate; (2) action of dextrin and fixed alkali hydroxides on silver nitrate or oxide; (3) action of tannin and fixed alkali carbonates on silver nitrate or carbonate. More complete accounts of this interesting subject will be found in the papers by M. Carey Lea (see *Proc. Am. Pharm. Assoc.*, for 1890, 1891, 1892).

Argentum Colloidale.—*Argentum solubile, Collargolum.—Colloidal or soluble silver*, E.; *Colloidales Silber, Credésches Silber*, G.—This preparation may be obtained by adding to 500 Cc. of a 10 per cent. silver nitrate solution, while stirring, a mixture composed of a solution of 280 Gm. of crystallized sodium citrate in 500 Cc. of water and 500 Cc. of a 30 per cent. solution of crystallized ferrous sulphate. The resulting precipitate is washed by decantation with dilute sodium citrate solution, dissolved in water, and reprecipitated by addition of absolute alcohol. In its moist state colloidal silver appears as a pale lilac, blue, or green-colored mass, which is soluble in 50 parts of water, forming a deep-red liquid. The addition of hydrochloric acid to this solution precipitates a spongy mass, consisting of silver chloride and metallic silver. Colloidal silver is also soluble in 500 parts of alcohol. While looked upon as an allotropic modification of silver, it contains but 97 per cent. of pure metal. Its chief use is in the preparation of Credé's Ointment (*Unguentum argenti colloidalis*, Credé), which is composed of colloidal silver 15 parts, water 5 parts, white wax 10 parts, and benzoinated lard 70 parts.

Tests.—The solution of chemically pure silver in hot diluted nitric acid, when precipitated by hydrochloric acid, yields a filtrate which is not darkened by hydrogen sulphide, and on evaporation to dryness leaves no residue.

Action and Uses.—Metallic silver is not employed in medicine as such, but because of its tendency to oxidation and its antiseptic properties it has been largely used in surgery, especially in the form of wire and plates.

Colloidal silver or Unguentum Credé has been introduced into medicine in the treatment of various forms of septic infection. Infectious pneumonia, pyæmia, septicæmia, peritonitis, pelvic abscess, and cystitis are said to be benefited by its use. It may either be given by intravenous injection, the dose being from $\frac{1}{2}$ to 1 grain (0.03–0.06 Gm.) in a 1 to 100 solution; or by inunction, the amount employed being from 20 to 40 grains (1.3–2.6 Gm.). The injection may be repeated daily if the nature of the case requires. The intravenous injection of this substance is not uncommonly followed either by a distinct chill or a chilly sensation in from 2 to 4 hours.

SILVER SALTS.

Argentaminum. *Argentamine, Ethylenediamine silver phosphate.*—Made by dissolving 10 parts of ethylenediamine and 10 parts of silver phosphate in 100 parts of water. A colorless alkaline solution, not precipitated by chlorides or albumin. It should be protected from light. An antiseptic, used in gonorrhœa.

Argenti Acetas. *Silver acetate.* $C_2H_3O_2Ag$.—Obtained by action of sodium acetate on silver nitrate. White minute crystals, of a disagreeable metallic taste, soluble in 100 parts of cold and 15 parts of boiling water, slightly soluble in alcohol. It is affected by light. Used as a reagent.

Argenti Chloridum. *Silver chloride.* AgCl.—Obtained by precipitation of silver nitrate by sodium chloride or hydrochloric acid. When wet, a white curdy, agglutinating substance, which darkens in light. Decomposed by caustic alkalies to oxide. Native chloride is known as *horn silver*. Silver chloride is soluble in ammonia water, cyanides, thiosulphates insoluble in water and dilute acids. It melts at 260° C. (500° F.) to a yellow liquid which solidifies into a colorless translucent horny mass (horn silver). Formerly often used as a substitute for silver nitrate in many affections.

Argenti Citras. *Silver citrate, Itrol.* $C_6H_5O_7Ag_3$.—Obtained by precipitating a solution of silver nitrate with a solution of citric acid neutralized by sodium bicarbonate, filtering, washing, and drying the precipitate on porous plates, without access of light. It is a white, odorless, heavy powder, moderately sensitive to light, soluble in 3800 parts of water. It is a non-corrosive antiseptic, used dry or in solution.

Argenti Fluoridum. *Silver fluoride.* AgF.—A very hygroscopic mass left on dissolving oxide or carbonate of silver in hydrofluoric acid and evaporating to dryness. It has antiseptic properties.

Argenti Iodas. *Silver iodate.* $AgIO_3$.—A white crystalline difficultly soluble powder obtained by precipitating silver nitrate with potassium iodate solution; used externally and internally.

Argenti Iodidum. *Silver Iodide.* AgI.—This salt was dropped in U. S., 1900. It may be obtained by adding a solution of silver nitrate to a solution of potassium iodide, while stirring, filtering and washing the precipitate on a filter. Silver chloride, due to impurity of chloride in potassium iodide, may be removed by washing the precipitated silver iodide with dilute ammonia-water by decantation before filtering. It is a heavy, light-yellow, tasteless powder, unaltered by light if pure, insoluble in water, alcohol, or dilute acids, soluble in 2500 parts of stronger ammonia-water, and in potassium cyanide solution and sodium thiosulphate. The presence of chloride or bromide in silver iodide is detected by digesting it successively with a solution of ammonium carbonate and ammonia-water and acidifying the respective filtrates with nitric acid, when more than a slight opalescence indicates, in the first case, chloride, in the second, bromide. If a small quantity of chlorine-water be agitated with an excess of the salt, the filtrate acquires a dark-blue color on the addition of starch paste. Iodide of silver is practically never employed in medicine at the present time. It was formerly used in the treatment of syphilis, asthma, chorea, and pertussis. The dose is stated to be from ½ to 2 grains (0.03–0.12 Gm.).

Argenti Lactas. *Silver lactate, Actol.* $C_3H_5O_3Ag + H_2O$.—Obtained by dissolving silver carbonate (by precipitating silver nitrate with sodium carbonate) in diluted lactic acid (8 parts of 75 per cent. acid to 80 parts of water) and evaporating to crystallization. All work should be done in a dark room. Colorless needles easily affected by light, soluble in 15 parts of water. The salt is usually brown and gives a brownish or reddish solution. An aqueous solution of 1 : 300 to 1 : 500 is equivalent to a 0.1 per cent. mercuric chloride solution in disinfecting properties. The dry salt is irritating to wounds. Actol tablets are on the market, containing 0.2 Gm. of actol, each of which will make ½–1 liter of solution, which is used in place of mercuric chloride. Silk catgut and drains are made antiseptic by impregnation with actol solution, washing, and exposing to light until dark-brown.

Argenti Phosphas. *Silver phosphate.* Ag_3PO_4.—A yellow amorphous powder, obtained by the action of sodium phosphate on silver nitrate. It is insoluble in water, soluble in nitric acid and ammonia water.

Argenti Quinaseptolas. *Silver quinaseptolate, Silver oxyquinoline-sulphonate, Argentol.* $C_9H_5N(OH)SO_3Ag$.—Obtained by interaction between silver nitrate and sodium quinaseptolate. A yellow powder, difficultly soluble in cold water, alcohol, and ether, more soluble in hot water. Used as substitute for iodoform for wounds, and skin diseases, either as ointment (1–2 : 100) or solution (1 : 300–1000). It is decomposed by septic matter into silver and oxyquinoline. It should be protected from light.

Argenti Sulphas. *Silver sulphate.* Ag_2SO_4.—Formed by action of sodium sulphate on strong solution of silver nitrate, whereby a colorless crystalline powder is obtained, which is filtered, washed first with a little cold water and then diluted alcohol. It is soluble in 200 parts of cold, 70 parts of hot water. It is not particularly sensitive to light. Used as a reagent in chemistry.

Argenti Sulphophenas. *Argenti sulphocarbolas, Silver sulphocarbolate, Silver phenolsulphonate.* $C_6H_4(OH)SO_3Ag$.—Obtained by dissolving silver carbonate in paraphenolsulphonic acid and evaporating to crystallization in the dark. Colorless, odorless prismatic needles, of a metallic taste, soluble in 3 parts of water and 60 parts of alcohol; insoluble in ether, chloroform, or carbon disulphide. It is decomposed by light and when heated to 120° C. (248° F.). The aqueous solution is neutral, and gives a dark precipitate with an alkali and a white one (AgCl) with chlorides or hydrochloric acid. Antiseptic, used like itrol and argonin in eye diseases and wounds, and preferred to silver nitrate because non-corrosive.

Argonin. *Silver sodio-caseinate.*—Prepared by adding silver nitrate solution to the sodium compound of casein and precipitating by alcohol. The precipitate is washed with dilute alcohol and dried. It contains about 4 per cent. of silver. It is a fine white powder, difficultly soluble in cold, but easily soluble in hot water. Acids split it up into its components. Neither albumin nor sodium chloride is precipitated by it. It should be free from acid (HNO_3) or alkali and preserved in the dark. It is a non-irritant antiseptic, used in gonorrhœa, etc., in the form of a 0.5 per cent. solution.

Argyrol, chemically silver vitellin, is a proteid salt of silver introduced early in 1902, and occurs in black hygroscopic scales containing 30 per cent. of metallic silver. It is soluble in all proportions of water, the solutions keeping well without deteriorating. Argyrol solutions do not coagulate albumin or precipitate chlorides. It is not precipitated by alkalies, but is precipitated from the solution by zinc sulphate, lead acetate, liquor hydrastis, and by strong acids. *Action and Uses.*—Argyrol may be used locally in acute inflammations in as strong as 50 per cent. solution without producing pain or irritation. *Methods of Use.*—In acute gonorrhœa, as an abortive measure, injections of 2 drachms of 20 per cent. solution, every three hours, held in the urethra ten minutes. For regular treatment of acute gonorrhœa injections three times daily of 5 per cent. solution retained in urethra ten minutes. During the second week (after disappearance of gonococci) injections of 5 per cent. argyrol solution are alternated with

injections of astringents (zinc, lead, hydrastis, etc.). Chronic posterior urethritis, hand injections of 5 to 10 per cent. solutions; deep, instillation of 25 per cent. solution; irrigation with 1 to 1000 solution. Cystitis, injection of 1 ounce of 10 per cent. solution, which is allowed to remain in the bladder. The same method is also applicable in infection of the prostatic follicles. Purulent conjunctivitis (gonorhœal, neonatorum, etc.), flushing the conjunctiva with 25 to 50 per cent. solutions every three hours. Catarrhal conjunctivitis, free instillation of 5 to 20 per cent. solutions three times daily. Dacrocystitis and tracoma, 25 per cent. solution. Acute and chronic rhinitis, pharyngitis, laryngitis, otitis media, application (with swab or nebulizer) of 25 to 50 per cent. solutions once daily. Vaginitis, endometritis, cervical ulcerations, 50 per cent. solution by means of swab or tampons. Fissure and fistula of the anus, proctitis, inflamed hemorrhoids, suppositories of 10 to 25 per cent. argyrol in cacao butter. *Internal Administration.*—Argyrol is non-toxic and is not absorbed. 5 to 10 grains in capsules three times daily in gastric ulcer, gastritis, and gastro-enteritis. As an irrigating fluid, from 1 to 4 pints of 1 to 1000 solution by high rectal injection, twice daily in dysentery, ulcerative enteritis, mucous colitis, cholera infantum. Argyrol should be dispensed in aqueous solutions only, never in combination with other drugs. Argyrol stains on linen, hands, etc., may be immediately and completely removed by immersing in a 1 to 500 bichloride of mercury solution.

Nargol is a true chemical combination of silver in the strength of 10 per cent. with nucleinic acid derived from yeast. It is rapidly soluble in water, and is said to have a greater penetrating power than silver nitrate. It is also less irritating to mucous membranes. Nargol has been employed with great success in the treatment of gonorrhœa and in inflammation of the conjunctiva. It may be employed in solution or in the form of an ointment to old ulcers and suppurating wounds which need stimulation, and in which irritation is to be avoided. For conjunctivitis the solution should be from 2 to 5 per cent. strength; for gonorrhœal irrigations, 0.25 to 1 per cent. strength, or even as strong as 5 per cent. in very chronic cases.

Protargolum. *Protargol.*—A compound of albumin and silver. A yellowish powder, of weak metallic taste, soluble in 1 part of water. Solution is best effected by sprinkling the powder on the water and agitating or stirring in a beaker or dish. The solutions are brown in color and are not precipitated by alkalies, alkali sulphides, sodium chloride, albumin, or heat. Picric acid causes a yellow precipitate. The dry salt as well as the solution should be protected from light. It is an excellent non-irritant bactericide. A 5 per cent. solution may be used in the eye with scarcely any burning pain. A ¼–2 per cent. solution is used in acute gonorrhœa of men. In urethritis of women, 5–10 per cent. solutions may be used without irritation.

ARMORACIÆ RADIX, *Br.*—Horseradish Root.

Meerrettig, G.; *Raifort, Cram de Bretagne, Moutarde des moines*, Fr. Cod.; *Rabano rusticano*, Sp.

The fresh root of *Roripa Armoracia* (L.) Hitchcock (*Cochlearia A.* L.; *Nasturtium A.* Fries; *Cochlearia rusticana* Lam.; *Armoracia r.* Gærtn.; *A. sativa* Bernh.—Fam. *Cruciferæ*).

Origin.—A large perennial herb of eastern Europe, almost everywhere cultivated and commonly naturalized in North America and other countries. The grated and pickled root is a well-known condiment.

Description.—From 3 to 7 Dm. (1 to 2½ Ft.) long, and occasionally reaching 5 Cm. (2 In.) or more in thickness, cylindraceous, somewhat annulate above upon the one to several short crowns; externally light yellowish-brown, internally white and fleshy, the fracture short and sharp; transverse section exhibiting a thin bark, containing a number of prominent yellow thick-walled cells, a dark-colored cambium line, and a slightly radiate meditullium. The crowns show a large central pith; when bruised or broken, it exhales a very pungent odor; it has a sharply biting and acrid taste.

Constituents.—The pungent principle originates, as in mustard, through the decomposition of a glucoside, under the influence of water and a special enzyme. This oil is produced to the extent of about 0.05 per cent., and is almost identical with the volatile oil of mustard, having the same composition, but differing slightly in odor. In the raw condition it has a slight yellow coloration, which is removed by rectification, after which it becomes dark-colored with age. Its specific gravity is 1.01. The drug contains also a little bitter resin, with ordinary plant constituents. Mutschler found the fresh root to lose about 83 per cent. on drying, the ash amounting to 11.75 per cent. of this dried portion and consisting mainly of potassium and calcium salts.

Action and Uses.—Horseradish, in the fresh state or pickled, has a very pungent and acrid taste, irritates the fauces and the nostrils, and causes a flow of tears. It is a familiar condiment, especially for beef. It excites a sense of warmth in the stomach, stimulates the appetite, and promotes digestion. In excessive doses it occasions burning at the epigastrium, nausea, and vomiting. It augments the urine, and probably the

perspiration also, and gives to the former a peculiar odor. Externally applied, it reddens and sometimes blisters the skin. These qualities depend upon its volatile oil, which has at first a sweetish and then an extremely acrid taste and a pungent and very diffusive odor. Horseradish has had great renown as a remedy for scurvy, and the resemblance of its taste to that of scurvy-grass (*Cochlearia officinalis*) is noteworthy. It is advantageous as a condiment in many cases of dyspepsia with feeble appetite, oppression after eating, and flatulence, and in gastric debility attended with vomiting even when excited by reflex irritation. As a local irritant it is sometimes used to relieve toothache, to stimulate the fauces, to correct relaxed states of the mucous membranes, and to remove the hoarseness produced by congestion of the larynx. For these purposes it may be employed as a masticatory, or a strong infusion of it may be used as a gargle. It may be resorted to as a counterirritant in all the cases in which mustard is appropriate, to arouse sensibility, to relieve pain, excite motility, etc.

Cochlearia (*Scurvy-grass, Spoonwort*, E.; *Herba cochleariæ*, P. G.; *Löffelkraut*, G.; *Cochlearia, Herbe au scorbut*, Fr.; *Cochlearia*, F. It., Sp.) is the herb *Cochlearia officinalis* L. (*C. oblongifolia* DC.). The German Pharmacopœia defines it as the dried herb. It is a native of Europe, and is occasionally cultivated there and in other countries. The radical leaves are roundish-cordate to subreniform, obtuse, nearly entire; stem leaves ovate, sparingly angularly toothed, the lower petioled, the upper sessile and clasping; flowers in terminal racemes, white, cruciferous; pods globular-ovate, ascending, slightly laterally flattened, containing 4 red-brown seeds in each of the 2 cells; pungent, acrid, and bitterish, much of the pungency lost on drying. It contains, besides tannin and a bitter principle, a volatile oil similar to that of horseradish, according to Hoffman butylsulphocyanide ($CSN.C_4H_9$), its ammonia compound melting at 135° C. (275° F.). An oil obtained synthetically from butylamine had the composition of oil of scurvy-grass, but a different odor, and yielded an ammonia compound fusing at 90° C. (192° F.). The uses of scurvy-grass are precisely those of horseradish, its action being only slightly modified by the presence of the bitter constituent.

ARNICA, *U. S.*—Arnica Flowers.

Leopard's-bane, Mountain tobacco, Wolf's-bane, E.; *Arnika, Blutblume, Fallkraut, Gemsblume*, G.; *Arnique*, Fr.

The dried flower-heads of *Arnica montana* L. (*Doronicum Arnica* H. Br.—Fam. *Compositæ*).

Official in most pharmacopœias (not Br.). Most require the florets only, by the rejection of the involucre, which necessarily involves that of the receptacle also.

Fig. 34.

Arnica: *a*, involucre; *b*, receptacle; *c*, ray-floret; *d*, disk-floret (× 1½).

The arnica plant is native of Europe, growing chiefly in Germany, Switzerland, and northward. The genus contains a large number of species, which have been much confused, so that the range-limits are somewhat in doubt. It probably does not grow in any part of America. It is a perennial, a foot or two high, the leaves chiefly radical and the flower-heads few, terminating long peduncles.

Description.—Heads about 2 Cm. (¾ In.) long; involucre campanulate-turbinate, ⅔ the length of the head, 1.2 to 2 Cm. (½ to ¾ In.) broad, the scales 1- to 2-serialled, appressed, green,

shortly and sparsely gray-hairy, oblong, obtusish; receptacle slightly convex, densely short-hairy and pitted; rays about 16, spreading or reflexed, bright-yellow, the ligulate portion 2 to 2.5 Cm. (¾ to 1 In.) long, nearly 0.6 Cm. (¼ In.) broad, oblong, 3-toothed, 7- to 9-nerved, pistillate, fertile; disk-flowers perfect, tubular, 5-toothed, of a deeper yellow, their akenes nearly 0.6 Cm. (¼ In.) long, slender, tapering sharply to the base, flattened, 5-ribbed, pubescent, the pappus nearly a half longer than the akene, a little shorter than the corolla, of a single circle of nearly white, barbellate bristles; anthers not tailed at the base.

This drug has been subject to extensive adulteration. *Inula*, of several species, has the involucral scales in several or many series, the receptacle not hairy, the anther-bases long-tailed. *Doronicum* (including *Aronicum*) has the receptacle naked and the rays only 4- or 5-nerved. The receptacles, when present, are very liable to be infested with larvæ. Collected in the early stage of flowering, a little preceding full expansion, the drug is not only more active, but is also less liable to the presence of the larvæ.

Constituents.—The active constituents are 4 per cent. of *arnicin* (see Arnicæ Radix) and 0.04–0.07 per cent. of a butyraceous volatile oil, distinct from that of the rhizome. The bitter alkaloid *arnicine*, with crystallizable salts, was reported by Bastick in 1851, but has not since been reported.

Pharmaceutical Preparations.—Fluidextract of Arnica Flowers, N. F.; Tincture of Arnica, U. S. P.

Action and Uses.—When locally applied, arnica flowers produce a sensation of warmth. If the skin be delicate, they cause more or less irritation and at times an extensive dermatitis. Given internally in moderate amount, arnica slows the heart and increases arterial tension. In large amounts it depresses the vagus nerve, increases the rapidity of the pulse, and causes diuresis and diaphoresis. In overdose the drug causes irritation of the throat, burning pain in the stomach, nausea, vomiting, frontal headache, vertigo, and insomnia. Both the pulse and respiration are accelerated. Later, exhaustion, more or less sweating, dilatation of the pupils, occasionally muscular spasms, cold extremities, and an irregular and infrequent pulse result. Death may occur if 3 or more ounces are swallowed. The nauseating and irritating properties of arnica flowers probably depend upon the eggs and larvæ of the *Atheris Maculatus*, which is commonly found admixed with them.

Locally the drug is employed in the treatment of sprains, bruises, abraded surfaces, and local paralyses. It is rarely employed internally in this country, but has been recommended in dysentery, gout, rheumatism, intermittent fever, secondary anæmias, and various nervous affections.

Arnica is usually administered in the form of a tincture in the dose of from 15 to 30 minims (1–2 Cc.). A decoction may be made with 50 Gm. of the drug and 1000 Cc. of water, and given in the dose of 1 to 2 tablespoonfuls (16–30 Cc.). The dose of the drug in substance is 10 to 30 grains (0.6–2 Gm.).

ARNICÆ RADIX.—Arnica Root.

The dried rhizome and roots of *Arnica montana* L. (Fam. *Compositæ*). Official in most pharmacopœias.

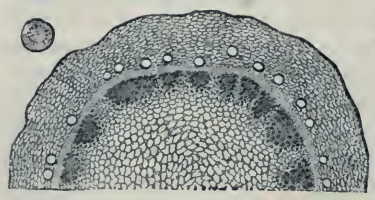
Description.—Rhizome oblique, about 5 Cm. (2 In.) long and 3 or 4 Mm. (⅛ In.) thick, often bearing hairy remains of petioles and stem-base at one end; externally reddish-brown, broadly annulate with the scars of amplexicaul leaves; under surface supplied with numerous rather coarse roots; internally whitish, with a rather thick bark, containing a circle of large distant resin-cells surrounding the short yellowish wood-wedges; pith large and spongy. Roots brittle, lighter than the rhizome, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter.

The powder contains neither starch-grains nor crystals of calcium oxalate.

Various adulterants of, or accidental admixtures with, arnica root have been reported, but none of them, excepting possibly other species of Arnica, possess the rings, the circle of large resin-cells, or the peculiar aroma, while starch-grains are present in most of them.

Constituents.—Arnica root contains 10 per cent. of inulin, with gum, wax, salts, 0.5 to 1 per cent. of volatile oil, and arnicin. The volatile oil is yellowish, has a radish-like odor, and consists chiefly of the methyl-ether of hydrothymoquinone and isobutyric acid phlorylester (*Sigel*). *Arnicin* ($C_{20}H_{30}O_4$ or $C_{35}H_{54}O_7$), an amorphous, terebinthinate, bitter, non-volatile principle, is soluble in alcohol, ether, and alkalies, almost insoluble in water, and is precipitated by tannin. Pavesi's arnicin is a mixture,

Fig. 35.

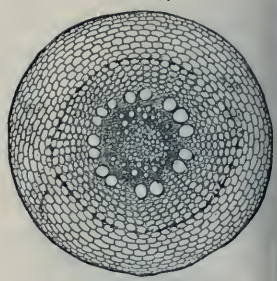


Arnica: transverse section of rhizome, magnified.

Fig. 36.

Arnica rhizome (somewhat reduced).

Fig. 37.



Arnica: section through root, magnified 25 diam.

Action and Uses.—Arnica root possesses the same action as that of the flowers. It is devoid of the irritating principle contained in the larvæ which accompany the flowers, and for this reason is a better drug for internal administration. It is given in substance in the dose of 10 to 30 grains (0.60–2 Gm.). The dose of the tincture is 15 to 30 minims (1–2 Cc.); of the fluid extract, 5 to 10 minims (0.3–0.6 Cc.); of the extract, 3 to 5 grains (0.20–0.30 Cc.).

ARNOTTA.—Annota; Annatto.

Orellana, Orleana.—Orlean, G.; *Rocou, Terre de la Nouvelle-Orléans*, F.; *Achiote, Achiotillo*, Sp.

A coloring-matter obtained from the seeds of *Bixa Orellana* L. (Fam. *Bixaceæ*).

This is a rather small tree, in habit somewhat resembling a very large plum tree, native of tropical America, and very extensively cultivated there and in other tropical countries for the sake of this product. The capsules, about as large as hen's eggs and somewhat resembling gigantic beech-nut capsules, are short-ovoid, with impressed base, and spinose-tuberculate. The numerous seeds, whitish but apparently red from the pulpy covering, are angularly obovoid and about 3 Mm. ($\frac{1}{8}$ In.) long. There are various methods for extracting and preparing the arnotta, some of them extremely filthy, but in general the seeds are soaked or allowed to ferment in water, rubbed between the hands and upon a sieve, crushed, and finally completely mashed and again washed with water. The coloring-matter subsides and is formed into cakes; the water likewise contains a coloring-matter. The cakes are either plastic or hard, of a nearly blood-red color, red-brown on exposure, of a peculiar odor and a disagreeable saline and bitter taste. Arnotta is nearly insoluble in water, coloring it yellow, but dissolves almost completely in alcohol, ether, fixed oils, and alkalies, with an orange-red or dark-red color.

The substance is enormously adulterated. Earthy matters of various kinds are readily separated by their insolubility in hot alcohol, while metallic salts are detected by appropriate chemical tests. Damaged flour, from various grains, and other vegetable dualterants are readily recognized by an examination of their starch-grains, those of arnotta being very few and small, with an elongated and stellate hilum, much resembling those of peas and beans.

Arnotta contains a fatty acid, a turpentine-like body, and *bixin* ($C_{28}H_{34}O_5$), which forms glistening red crystals. *Orellin*, a yellow coloring-matter, has also been described, but Zwick failed to find it. The air-dried seeds yield 5.15 per cent. of ash, chiefly phosphate of potassium and silica.

Action and Uses.—Arnotta was at one time employed in medicine to a limited extent, but its use has now been abandoned. It finds some use in pharmacy as a coloring for plasters and ointments, and in the arts as a yellow dye for silks and other fabrics. It is the chief constituent of the butter and cheese coloring preparations and of the various polishes for russet leather. Butter color may be prepared by digesting arnotta with twice its weight of alcohol until it is completely disintegrated, and then mixing with 5 times its weight of olive oil and heating until the alcohol is evaporated, or it may be made by dissolving 1 part of extract of arnotta in 10 parts of olive oil.

ARSENI IODIDUM, *U. S.*—Arsenous Iodide.

Arsenii iodidum, Br.; *Arsenicum (Arsenum) jodatum.—Arsenious iodide*, E.; *Iodure d'arsenic*, Fr.; *Arsentrijodid*, G.

Formula, AsI_3. Molecular weight, 452.10.

It should contain not less than 82.7 per cent. of iodine, and 16.3 per cent. of metallic arsenic. It should be kept in amber-colored, glass-stoppered vials, in a cool place, carefully protected from light.—U. S.

Preparation.—According to the U. S. P. 1870, 75 parts of metallic arsenic and 380 parts of iodine are intimately triturated and then placed in a small flask and heated until liquefaction occurs. Any sublimed iodine is washed down by running the molten mass upon the sides of the flask. The mass is finally poured upon a porcelain slab and, when cold, broken into pieces and bottled. Although sufficiently pure for medicinal purposes, it is difficult to produce in this way a uniform chemical compound, which, according to Berzelius, is obtained on subjecting the mechanical mixture to sublimation from a retort the body of which is completely imbedded in sand. Or the iodine is dissolved in carbon disulphide; the solution is gently heated, and, after the gradual addition of the powdered arsenic, is digested until the purple color of free iodine has disappeared; the clear solution is decanted if necessary, and the solvent distilled or evaporated, when the arsenous iodide is obtained in crystals, and may be recrystallized from alcohol. Or, according to Bamberger and Phillip, it may be made by mixing a hot solution of arsenous acid in hydrochloric acid with a concentrated solution of potassium iodide, and washing the precipitate with hydrochloric acid, specific gravity 1.12.

Properties.—Obtained by fusion, arsenous iodide is a glossy orange-red crystalline mass; if made by sublimation or crystallization, it appears in shining brick-red or orange-red hexagonal scales. It has an iodine-like odor and taste, and slowly gives off iodine on exposure to the air. Its density is 4.39. It is soluble, with a neutral reaction and without decomposition, in water, alcohol, ether, and carbon disulphide, but is gradually decomposed on being boiled with water or alcohol. It is soluble in 12 parts of water and in 28 parts of alcohol at 25° Cc. (77° F.). It is difficultly soluble in hydrochloric acid. The aqueous solution has a yellow color, is neutral to litmus-paper, and on standing gradually decomposes into arsenous and hydriodic acids. On passing hydrogen sulphide through the solution a lemon-yellow precipitate is thrown down. If the salt be heated with diluted nitric acid, vapor of iodine is given off. No loss of iodine occurs when it is heated on a boiling water-bath, but at higher temperatures the salt is completely volatilized.—U. S.

Tests.—The purity is ascertained by the complete solubility of the salt in water and alcohol, and by its volatilizing without residue on the application of heat. If 0.5 Gm. of the salt and 2 Gm. of sodium bicarbonate be dissolved in 50 Cc. of water, not less than 21.5 Cc. of tenth-normal iodine solution should be required to impart a slight yellow tint to the solution.—U. S.

Action and Uses.—This compound in small doses is an alterative, and in large ones an irritant poison. Its dose is so small that the iodine contained in it fails to make any impression upon the organism. The remedy may be employed in all conditions for which arsenic trioxide is beneficial (see ARSENI TRIOXIDUM); but it has been especially recommended in psoriasis, lepra, chronic eczema, and lupus. The symptoms and treatment of poisoning by this drug are practically the same as those of arsenic trioxide. The dose is $\frac{1}{20}$ of a grain (0.003 Gm.), gradually increased until the effects of the remedy are apparent.

ARSENI TRIOXIDUM, *U. S.*—Arsenic Trioxide.

Acidum arsenosum, U. S., 1890; *Acidum arseniosum*, Br.; *Acidum arsenicosum*, P. G.; *Arsenicum album.—Arsenic, White arsenic, Arsenous acid, Arsenious anhydride*, E.; *Acide arsénieux, Arsenic blanc*, Fr. Cod.; *Arsenigesäure, Weisser Arsenik*, G.; *Arsenico bianco*, It.; *Arsenico blanco*, Sp.

Formula, As_2O_3. Molecular weight, 196.44.

It should contain not less than 99.8 per cent. of pure arsenic trioxide.—U. S.

The name *arsenous acid* is a misnomer, since the oxide is an acid anhydride and has no acid properties until it unites with water.

Vapor density determinations show that the formula of the oxide is As_4O_6 (Mitscherlich). At very high temperatures, 1700° C. (3092° F.), the molecule suffers dissociation, and the formula then is As_2O_3. However, it is customary and convenient to use the simpler formula As_2O_3 in reactions.

Occurrence and Preparation.—Arsenic trioxide appears to have been known since about the beginning of the Christian era, but was first distinguished from other arsenical compounds by Geber in the eighth century. It has been found in many mineral waters in minute proportion, and is obtained in large quantities as a by-product in roasting cobalt, nickel, tin, and even some silver ores, and particularly arsenical iron pyrites; the vapors are conducted through long tubes or chambers, where they are condensed in the form of a white powder, formerly called *flowers of arsenic*. This is not pure, but contains some metallic arsenic, arsenic sulphide, dirt, etc., from which it is purified by resublimation. That consumed in this country is imported mostly from Europe. The English product comes into the market as a finely ground crystalline powder.

Properties.—Arsenic trioxide occurs in heavy inodorous masses, which are at first glass-like, transparent, and have a conchoidal fracture, but become superficially white, opaque, and of a waxy lustre, the change penetrating gradually to the interior, so that ultimately the entire mass is converted into a porcelain-like mass, the formation of which is dependent upon a molecular change, the amorphous glass-like arsenic trioxide becoming indistinctly crystalline. The specific gravity of the vitreous variety is 3.7385, and of the opaque variety 3.699 (Guibourt). When heated in a sealed tube arsenic trioxide may be melted to a thick liquid, and again be obtained as a glass-like mass, or, when very slowly cooled, in crystals of different form. Heated in an open test-tube, the amorphous oxide melts at about 200° C. (392° F.) and volatilizes, while the crystalline variety volatilizes without melting. The vapor is condensed on the cool parts of the tube in minute crystals easily recognized under a lens as characteristic regular octahedra. When thrown upon burning charcoal, it is reduced to the metallic state and vaporized, arsenic trioxide again being produced and an alliaceous odor emitted. It does not readily mix with water; its solution has a slight but distinct metallic taste and a feeble acid reaction. The crystalline acid is less soluble than the amorphous, but one is under various circumstances converted into the other. At 25° C. (77° F.) the vitreous variety is soluble in about 30 parts of cold water, while the porcelain-like requires about 100 parts; both are slowly but completely soluble in 15 parts of boiling water (U. S.). According to the P. G., at 15° C. (59° F.) the vitreous oxide is soluble in 30 parts, the porcelain-like oxide in 80 parts of water, and both are soluble in 15 parts of boiling water. The acid does not volatilize with vapors of boiling water. The British Pharmacopœia says the trioxide is soluble in 100 parts of cold water and in 10 of boiling water. H. Erdmann (*Lehrbuch der Anorg. Chemie*, 1900) says that 1 Gm. of crystallized oxide is soluble in 355 Gm. of water at 15° C. (59° F.) and 46 Gm. of water at 100° C. (212° F.). 1 Gm. of amorphous oxide is soluble in 108 Gm. of water at 15° C. (59° F.) and in 30 Gm. of water at 100° C. (212° F.). There seems to be a lack of agreement in the statements of various writers in regard to the solubility of the oxide.

Solutions of both the amorphous and crystalline varieties pass readily through the septum of the dialyzer. By the aid of heat glycerin dissolves the oxide slowly but freely, and deposits again a portion of it on dilution with water. Oil of turpentine dissolves only the glassy variety. Arsenic trioxide is insoluble in ether and chloroform, quite sparingly soluble in alcohol, but combines with fixed oils when heated, forming a plaster-like mass; several acids increase its solubility in water, particularly hydrochloric and tartaric acids.

Powdered arsenic trioxide is often adulterated; hence it should not be employed for medicinal purposes unless its purity has previously been established. When rubbing the hard masses of vitreous or porcelain-like oxide to powder, sufficient alcohol should be sprinkled over it to prevent the dust from rising, and the mouth and nostrils should be protected by a moist sponge. When larger quantities are powdered, it is even advisable to protect the eyes and the bare hands.

Tests.—Arsenic trioxide is volatilized completely at a temperature of 200° C. (392° F.), U. S., 204.5° C. (400° F.), Br., and yields a white sublimate free from gray or orange-colored portions (absence of metallic arsenic and sulphides). 0.1 Gm. of the oxide dissolved with 1 Gm. of sodium bicarbonate in 20 Cc. of water by the aid of heat should decolorize not less than 20.32 Cc. of tenth-normal iodine solution, corresponding to

at least 99.8 per cent. of oxide.—U. S. The P. G. permits a 98.8 per cent. oxide. The British Pharmacopœia requirement is higher, since 0.25 Gm. of oxide must decolorize at least 50.8 Cc. of iodine solution, corresponding to at least 99.9 per cent. (H = 1; O = 15.88). The reaction occurring in this test is shown by the equation: $As_2O_3 + 5H_2O + 2I_2 = 2H_3AsO_4 + 4HI$; 1 molecular weight of arsenic trioxide is oxidized by 4 atomic weights of iodine, with the formation of 2 molecules of arsenic and 4 of hydriodic acid. The admixture of arsenic acid is detected by agitating an excess of the powder with cold alcohol, filtering, evaporating, and neutralizing with ammonia, when silver nitrate will produce a red-brown precipitate. Arsenic trioxide should be completely soluble in 10 parts of warm ammonia-water, forming a colorless solution, which should not be colored yellow nor produce a yellow precipitate upon addition of hydrochloric acid (absence of arsenic sulphide and other impurities).

A solution of arsenic trioxide gives with ammonio-silver nitrate (silver nitrate solution to which ammonia-water is added until the precipitate formed is just dissolved) a lemon-yellow precipitate, Ag_3AsO_3, soluble in nitric acid and also in excess of ammonia-water. The latter solution when heated deposits metallic silver (distinction from arsenic acid or its salts, which, moreover, give a reddish-brown silver arsenate, Ag_3AsO_4).

Ammonio-copper sulphate gives with a solution of the oxide a bright green precipitate of copper arsenite, $CuHAsO_3$ (Scheele's green), which is soluble in caustic alkali, giving a blue solution. On boiling this, red cuprous oxide is deposited and alkali arsenate is left in solution. This is a delicate test, and serves to distinguish quite sharply between arsenous and arsenic solutions, the latter giving a green precipitate, insoluble in alkalies and not precipitating red cuprous oxide on boiling.

Detection of Arsenic.—Several methods may be employed for detecting small quantities of arsenic, as, for example, in solutions, in which the tests described above are not sufficiently sensitive. Hydrogen sulphide precipitates a bright-yellow sulphide from *acidulated* solutions. In the case of *arsenous* compounds the precipitate forms immediately, but when arsenates are present the precipitate at first does not form at all in the cold; on standing for some time, it slowly forms. Warming the solution to 70° C. (158° F.) facilitates the precipitation, and yellow *pentasulphide* is obtained. If sulphurous acid is added to the solution of arsenate, the arsenic acid is reduced to arsenous acid, and hydrogen sulphide passed into such a solution precipitates yellow *arsenous* sulphide immediately. Neutral or alkaline solutions containing arsenic do not give a precipitate with hydrogen sulphide; they must first be acidulated with hydrochloric acid. For quantitative determination, hydrogen sulphide must be passed into the solution for about 10 hours, after which the solution is allowed to stand in a warm place 15 hours or more. If not mixed with other metals, the precipitate thus obtained is pretty characteristic, since only two other metals yield under the same circumstances precipitates of sulphides having a similar color, namely, *cadmium* and tin in *stannic* compounds. *Cadmium sulphide* has a bright lemon-yellow color, but is distinguished readily from the corresponding arsenic compound by being completely insoluble in potassium hydroxide, ammonia, and ammonium sulphide; on the other hand, cadmium sulphide dissolves completely in strong hydrochloric acid, forming cadmium chloride, and giving off hydrogen sulphide, while arsenic sulphide is insoluble in the acid mentioned. *Stannic sulphide* has a dusky-yellow color, and dissolves in potassium hydroxide, ammonia, and ammonium sulphide, but differs from arsenic sulphide not only in the shade of color, but also in its complete solubility in strong hydrochloric acid. If the precipitate is not a pure yellow, but seems to contain sulphides of other metals, the arsenic sulphide, together with any antimony or tin sulphide that may possibly be present, may be extracted by digesting the mixed sulphides with warm ammonium sulphide, filtering, and washing the residue with water. The filtrate will contain the three sulphides, which may be reprecipitated by acidulating with hydrochloric acid. Arsenic sulphide is separated from any possible antimony and tin sulphides by treatment with warm concentrated hydrochloric acid, which leaves the arsenic sulphide undissolved, while antimony and tin sulphides pass into solution.

In forensic cases, a better and surer proof of the presence of arsenic is the liberation of the metal itself, with subsequent conversion into the striking and characteristic octahedra and tetrahedra of arsenic trioxide. This is accomplished in the following manner: The arsenous sulphide, as obtained above, is treated with a little ammonia-water, to which are

added a few granules of sodium carbonate, and evaporated to dryness in a dish. The residue is mixed with about twelve times its bulk of *cyanide flux* (an intimate mixture of 1 part of potassium cyanide and 3 parts of anhydrous sodium carbonate) and introduced into the bulb of a Berzelius hard-glass reduction-tube (Fig. 38), where it is heated to

Fig. 38.

Reduction-tube of Berzelius.

redness. An iron-gray, metallic arsenic ring sublimes into the cooler part of the tube, accompanied by a garlic-like odor. The sublimate volatilizes on the application of heat, and condenses again in a cooler part of the tube, and, if atmospheric air has been admitted, is converted partly or entirely into minute brilliant octahedral crystals of arsenic trioxide (Fig. 40).

Arsenic trioxide, which is usually met with in cases of accidental or criminal poisoning, yields, if heated in a narrow tube (see Fig. 39), the crystalline sublimate described above; and if mixed with charcoal or cyanide flux, the sublimate will, as in the above case, con-

Fig. 39.

Reduction-tube with sublimate of arsenic trioxide.

sist of metallic arsenic, and this, on being sublimed in the presence of air, will yield the octahedral crystals of arsenic trioxide.

Fig. 40.

Sublimate of arsenic trioxide, magnified.

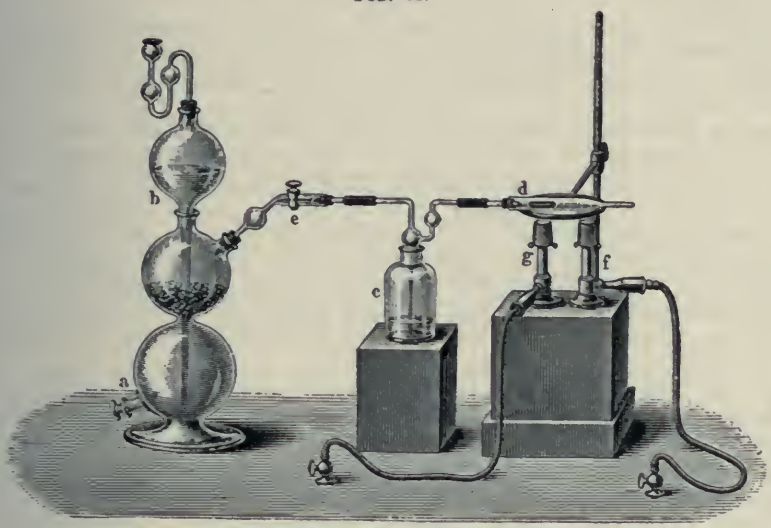
As it is often difficult or even impossible to obtain glass free from arsenic, Fresenius and v. Babo have modified the above method so as to be free from any error due to arsenic in glass. The mixture of arsenic sulphide and cyanide flux is heated in a small porcelain boat resting inside of a glass tube. Fig. 6 represents the apparatus: *a* is a carbon dioxide generator, and *d* a bottle containing the porcelain boat, which first is heated near the tapering end to low redness, and then under the boat metallic arsenic sublimes into the narrowed end in an atmosphere of carbon dioxide, which prevents oxidation to the oxide. In this form the test is extremely delicate. It will give a recognizable mirror with as little as $\frac{1}{6500}$ grain (0.00001 Gm.) of arsenic trioxide. It is simpler, cleaner, and superior to all other methods for producing metallic arsenic from the sulphide, for which it is especially adapted.

In the presence of much organic matter the detection of arsenic is a more complicated process, involving the separation of most of the organic matter, which Fresenius and v. Babo accomplished by heating the mass on a water-bath with hydrochloric acid, and adding to it potassium chlorate in small quantities until a thin liquid is produced; if the heat be not raised beyond the temperature of boiling water, no arsenic chloride will be volatilized, but the mixture becomes more liquid in proportion as the solid organic substances are destroyed. The liquid is then filtered, the clear filtrate saturated with hydrogen sulphide, and the precipitate, which contains organic matter, treated with strong nitric acid and subsequently fused with pure sodium nitrate, whereby the organic compounds are destroyed completely, and the antimony and arsenic are converted into soluble arsenate and insoluble antimonate of sodium. On mixing this residue intimately with about twelve times its weight of an exsiccated mixture composed of sodium carbonate 3 parts and potassium cyanide 1 part, the powder may be heated to redness in a reducing-tube in a current of dry carbon dioxide, when a mirror of metallic arsenic will be obtained, while the presence of antimony, tin, and other metals will not interfere with the result. The mass obtained after the destruction of the

organic matter and fusion with sodium nitrate may be dissolved in water, and this solution, after acidulation with hydrochloric acid, may then be treated again with hydrogen sulphide, or in Marsh's apparatus—in the latter case, after evaporation with an excess of sulphuric acid to expel the nitric acid.

The destruction of the organic matter, as described above, may in some cases be omitted, the material being boiled simply with water and the filtrate acidulated with hydrochloric acid, previous to passing hydrogen sulphide through it. A solution suitable for the purpose may likewise be obtained by the process of dialysis, whereby mucous, amylaceous, and albuminous substances are left behind, while the dialyzed liquid contains the arsenous acid, besides organic and inorganic salts.

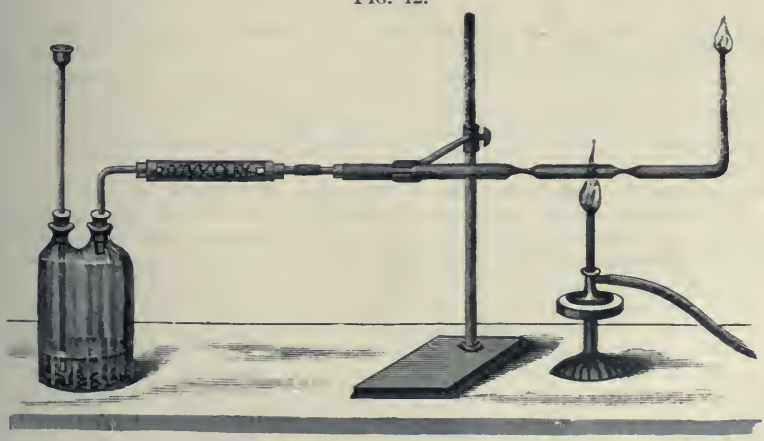
Fig. 41.



Apparatus for demonstrating Fresenius and v. Babo's test for arsenic.

Marsh's test depends upon the formation of hydrogen arsenide (arsine) by the action of nascent hydrogen upon the oxygen compounds of arsenic. A simple form of Marsh's apparatus is shown in Fig. 42. Hydrogen is liberated by zinc from an acid in a suitable flask and dried by conducting it through a tube filled with fragments of calcium chloride. After the air has been expelled completely and the apparatus filled with hydrogen, some of

Fig. 42.



Marsh's test for arsenic.

the liquid to be tested is introduced through the funnel-tube, and the escaping gas ignited. Upon holding a piece of porcelain in the flame, a brown-black spot of metallic arsenic will

be deposited, which will dissolve quickly on the addition of a little chlorinated lime or chlorinated soda (Bischoff, 1840). Antimony compounds will yield a similar spot, which, however, is not affected by the hypochlorites. When a dry beaker or test-tube is held over the jet, arsenic trioxide is deposited upon the inside, and may be recognized by its crystalline form; and after dissolving it in a little hot water a yellow precipitate will be obtained on the addition of solution of silver-ammonium nitrate. Antimony similarly treated gives no precipitate. The delivery-tube, which should be of hard glass, may be heated to redness in the flame of a gas-lamp, when the hydrogen arsenide will be decomposed, metallic arsenic being deposited. Antimony gives a similar reaction, but the two metals may be distinguished by heating the deposit in contact with air, when the arsenic will be converted into crystallized arsenic trioxide; or hydrogen sulphide may be passed through the tube and the deposit gently heated, when the arsenic will be converted into yellow sulphide and the antimony into orange sulphide. On now passing dry hydrochloric acid through the tube the antimony sulphide will disappear and the arsenic sulphide remain unaffected. (For the disturbing effect of selenium in the Marsh test, see Acidum Selenosum.)

On passing the hydrogen gas from the delivery-tube through lead acetate, to remove any H_2S, into a solution of silver nitrate, a black precipitate will be produced both by antimony and arsenic. If the former, the deposit will consist of a compound of antimony and silver; if the latter, metallic silver only is precipitated, while the solution contains the arsenic as arsenous acid mixed with the excess of silver salt, and on cautiously neutralizing with ammonia a yellow precipitate of silver arsenite is obtained.

Gutzeit's Test (*Phar. Zeitung*, 1879, p. 263).—Into a test-tube (about 6 by ½ inch) place a single piece of pure zinc (weighing about 1 Gm.), and add about 5 Cc. of pure 5 per cent. sulphuric acid; now add the liquid to be tested, which should not be alkaline nor materially increase the volume of the contents of the tube. At once fasten over the mouth of the test-tube a cap made of three thicknesses of pure filter-paper free from dust, and apply to the upper paper 1 drop of a saturated aqueous solution of silver nitrate containing about 1 per cent. of nitric acid. Place the tube at once in a box, rigidly excluding light, and examine the paper cap after a while. A bright-yellow stain will appear upon the paper—rapidly if the amount of arsenic be considerable, slowly if the amount be small; if the yellow stain be moistened with water, the color changes to brown or black. (Antimony colors the spot black or brown without a previous yellow coloration.) The action of hydrogen arsenide upon silver nitrate in the absence of water takes place with the formation of a yellow compound; thus, $AsH_3 + 6AgNO_3 = Ag_3As3(AgNO_3) + 3HNO_3$. When water is added, metallic silver is separated, showing a brown or black color: $Ag_3As3(AgNO_3) + 3H_2O = 6Ag + 3HNO_3 + H_3AsO_3$. Since hydrogen phosphide and hydrogen sulphide produce yellow-colored compounds under the conditions stated above, the zinc used in testing must be absolutely free from sulphur and phosphorus.

Modified Gutzeit's Test (U. S. P.).—The efficiency of this test depends upon a strict adherence to the conditions described below:

Reagents.—*Zinc.*—This should be in a granulated or fine mossy condition and free from arsenic, sulphur, and phosphorus, and should not contain more than 0.1 per cent. of iron. It should otherwise respond to all the tests given under zinc.

Hydrochloric Acid (8 per cent.).—Mix 18 Cc. of hydrochloric acid with water sufficient to measure 100 Cc.

Mercuric Chloride Test-paper.—By means of a glass rod transfer a drop of a saturated alcoholic solution of mercuric chloride to the centre of a piece of white filter-paper (preferably the kind used for quantitative analysis) of about 4 Cm. diameter; after drying, this paper is twice successively moistened with the reagent and dried. It is not necessary to moisten the paper with alcohol or the reagent while using it.

Lead Acetate Test-gauze.—A piece of cheese cloth, about 1 decimeter square, is thoroughly impregnated with lead acetate test-solution, and the excess of fluid removed by pressure.

Test-flask.—Select a flask of the capacity of about 60 to 75 Cc., with a neck of about 5 to 6 Cm. in length and about 1 Cm. in diameter.

Preparation of the Chemical to be Tested.—To 5 Cc. of the aqueous solution of the chemical (1 in 10) or to a solution in 5 Cc. of water of the residue remaining after undergoing special treatment, 1 Cc. of a mixture of equal parts of sulphuric acid and water is added, followed by 10 Cc. of a freshly prepared saturated solution of sulphurous acid. This solution, contained in a small beaker, is heated upon a bath of boiling water until free from excess of sulphurous acid, and its volume has been reduced to 5 Cc.

THE TEST.—Before applying this test for the presence of arsenic in chemicals, a preliminary blank test should be made as follows, in order to establish the freedom of the reagents from arsenic, sulphur, and phosphorus, or any interfering contaminations: Into the flask are introduced 2 Gm. of zinc, 20 Cc. of the diluted hydrochloric acid, and 5 Cc. of water; and into the neck of the flask is inserted the lead acetate test-gauze, pressed with sufficient firmness to retain its place. About 1 Cm. space should be allowed above the gauze; the lip of the flask, after careful cleansing, is securely covered by folding over it the mercuric chloride test-paper. The reaction is allowed to proceed until the greater portion of the zinc has dissolved, which may require from ½ to 2 hours, when, if no trace of a yellow to orange-colored deposit is distinguishable upon the inner surface of the paper test-cap, a direct test may be applied at once. If a black stain is produced, sulphur is present, which has escaped absorption by the lead acetate gauze, in which case the gauze should be remoistened with the test-solution. While the blank test is being carried out, another flask should be charged in a like manner with 2 Gm. of zinc and 20 Cc. of the diluted hydrochloric acid, followed by the 5 Cc. of the solution of the chemical (1 in 10) to be tested, which has undergone reduction as directed (under *Preparation of the Chemical*); the lead acetate gauze is then introduced, and after cleansing the lip of the flask the mercuric chloride cap is folded over the top. After the evolution of hydrogen has proceeded for 30 minutes, no distinct yellow stain should be visible upon the inner side of the mercuric chloride test-cap.

The presence of arsenic much in excess of the permissible limit (1 in 100,000) is manifested by the formation of a distinct yellow to orange spot, according to the quantity present. Antimony produces a dark-gray to brownish-black coloration.

Bettendorf's Test (1869).—On adding arsenical solution to a solution of stannous chloride in strong hydrochloric acid, specific gravity not less than 1.123, a gradual or, on heating, a somewhat rapid, reduction to metallic arsenic takes place, the deposit having a brown or black color according to quantity. Dilution with water and the presence of nitric acid or nitrates interfere with the reaction. Antimony is not reduced by this test.

The U. S. P. prescribes the following method of applying this test: To a solution of the prescribed quantity of the substance to be tested in 5 Cc. of pure concentrated hydrochloric acid and contained in a clean test-tube, 5 Cc. of a saturated solution of freshly prepared stannous chloride in pure concentrated hydrochloric acid are added; after heating for 15 minutes while immersed in a bath of boiling water, the tube is allowed to stand for 1 hour. Not the faintest brownish tint should become manifest when viewed by reflected light against a white surface, or viewed from above when placed over a pure white surface, and compared with a mixture of 5 Cc. each of pure concentrated hydrochloric acid and saturated solution of stannous chloride, prepared under like conditions, which should remain colorless.

Note.—It is absolutely necessary that the solution of stannous chloride be freshly prepared, and sulphates, sulphites, and sulphides be absent from the reagents and the chemicals being tested.

Reinsch's Test (1843).—If an arsenical solution is strongly acidulated with hydrochloric acid, and heated to boiling in the presence of a thin slip of bright copper—or, according to A. S. Taylor, preferably of finest copper gauze—the copper will become tarnished by the deposition upon it of metallic arsenic, the film having a bluish or iron-gray color according to quantity; the presence of nitric acid interferes with the reaction. The copper is washed with water, dried, and heated in a narrow test- or reduction-tube, when arsenic trioxide will be sublimed in the form of octahedral crystals. If the arsenic is present as arsenate, 2 volumes of concentrated hydrochloric acid must be added to make the test succeed. Antimony and other metals also give a dark coat on copper.

Fleitmann's Test, like the process of Marsh with its numerous modifications, depends upon the generation of hydrogen arsenide; instead of an acid, however, a strong solution of potassium or sodium hydroxide is employed, which has the advantage of preventing the formation of hydrogen antimonide If the gas is generated in a test-tube the orifice of which is covered with a piece of filter-paper moistened with a solution of silver nitrate, the appearance of a black spot will indicate the presence of arsenic. In applying this test, care must be taken to prevent the paper from coming in contact with the alkaline liquid, which would produce a similar color. A plug of cotton loosely inserted in the upper part of the tube will prevent any spirting of the liquid. A strip of paper moistened with solution of lead acetate, if colored brown or black by the gas, would prove the presence of hydrogen sulphide.

Johnson proposed aluminum in connection with potassium hydroxide solution for the

generation of hydrogen. In this, as in the preceding case, the metals employed are previously to be tested for the presence of arsenic.

Much simpler is the modification by E. W. Davy (1876), who employs an amalgam prepared by warming 8 or 10 parts of mercury, and dropping upon it gradually in small pieces 1 part of metallic sodium. The amalgam should be used only in a neutral or alkaline liquid; the gas is generated by the action of the sodium upon water, and the presence of arsenic in it is recognized with silver nitrate, as stated above.

According to Scherer (*Zeit. f. anal. Chem.*), the delicacies of the wet tests are as follows: $AgNO_3$ detects $\frac{1}{20000}$ part of As; $CuSO_4$, $\frac{1}{13500}$ part; H_2S, $\frac{1}{640000}$ part; Reinsch's test, $\frac{1}{120000}$ part, or after boiling one-quarter of an hour, $\frac{1}{250000}$ part.

Precautions.—It is scarcely necessary to remark that when testing for arsenic all the reagents must be absolutely free from that metal. The purity of sulphuric acid and hydrochloric acid is ascertained most conveniently by Bettendorf's or Reinsch's process, and the purity of zinc by that of Gutzeit. The use of copper for the purpose referred to is not, as a rule, interfered with by its containing arsenic, but the presence of the latter may readily be detected, according to Odling (1863), by heating it in a retort with 6 times its weight of ferric chloride and an excess of hydrochloric acid, when chloride of arsenic will distil over and give the usual reactions of arsenic compounds.

In forensic analysis it is required usually that the arsenic be separated in the metallic state, and that the quantity of the poison be estimated. The former is accomplished by the methods described above; the latter, by weighing the metal deposited in the heated delivery-tube of Marsh's apparatus, either upon the glass or upon platinum introduced for the purpose, or by estimating it in the form of magnesium pyro-arsenate.

Pharmaceutical Preparations.—Solution of Arsenous Acid; Solution of Potassium Arsenite.

Action and Uses.—Arsenic trioxide and its preparations in medicinal dose may be considered as indirect stimulants to the circulatory, respiratory, and nervous systems, inasmuch as they are stimulants to all nervous and muscle protoplasm and are said to have a selective action upon the trophic nerves. In poisonous dose the drug is a powerful depressant to the entire organism, slowing the heart, decreasing blood-pressure, lessening reflex action and sensation to pain produced by heat or pinching, and eventually causing motor paralysis. Arsenic trioxide is an irritant to mucous membranes, and when concentrated causes violent inflammation. Upon the normal, unbroken skin it has little or no effect; but applied to that tissue when abraded it acts as a powerful caustic and produces deep destruction. In small doses arsenic trioxide distinctly decreases tissue-waste, and in large amounts increases the percentage of nitrogenous elements in the urine. It is slowly absorbed, and is gradually eliminated by the skin, kidney, bowels, saliva, and in the milk of nursing women.

Given in ascending doses, arsenic trioxide in its various forms is probably the best drug we have for chorea, acting almost as a specific. It is of value in both primary and secondary anæmias, and has no equal in the treatment of pernicious anæmia, leukæmia, and pseudo-leukæmia. It is said to be useful as an antiperiodic in intermittent fever, and is commonly employed in chronic malaria, malarial cachexia, and rheumatoid arthritis. Amenorrhœa, dysmenorrhœa, menorrhagia, and leucorrhœa, especially when associated with anæmia, are frequently benefited by its use. The drug is employed with benefit in asthma when due to depraved conditions of the mucous membrane. In those individuals with phthisical tendencies who are readily susceptible to cold and who suffer with chronic winter cough it is of service, and in many cases of advanced tuberculosis it may be given with excellent result. It may be used with advantage in chronic nasal catarrh, early coryza, hay fever, cancrum oris, and sore throat. Arsenic is useful in the vomiting of pregnancy, morning vomiting of drunkards, and in atonic dyspepsia. It relieves the pain of gastric cancer and gastric ulcer, and frequently prevents the vomiting which occurs in these conditions. It is recommended in the chronic diarrhœa of children and in the chronic gastric catarrh of hand-fed babies. As a remedy in dry scaly skin diseases, for example, psoriasis, lichen, lepra, and pemphigus, arsenic stands first; but in those lesions characterized by a moist condition it is distinctly harmful and should not be employed. It may be given with advantage in intercostal, facial, and supra-orbital neuralgias, especially when associated with anæmia or dependent upon malaria.

Locally applied in solution, the drug is employed for the removal of warts, corns,

and other epithelial growths. In the form of an arsenical paste, such as that recommended by Marsden—arsenic trioxide and powdered acacia, each 1 oz. (30 Gm.), and water 3 fluidounces (90 Cc.)—it has been employed in the removal of epitheliomata. If used in this way, a large amount should be applied for a short time, in order that it may produce destruction of the tissue rather than absorption of the drug. As its application is very painful, its employment is gradually being abandoned.

When given in full dose, arsenic causes puffiness of the lower eyelids and a sensation of stiffness in the muscles of the face. There are some laxity of the bowels and slight pain in the intestines. In certain susceptible individuals the drug may produce dermatitis or some other skin lesion. It occasionally affects the mucous membrane, producing coryza and gastric disorders.

When habitually taken in small doses, a certain tolerance to the drug is established, and eventually large quantities may be ingested without detriment. The Styrian peasants and the inhabitants of the Tyrol are said to frequently resort to the internal use of the drug in this manner, claiming that it lessens the respiratory distress which usually occurs in mountain-climbing.

Poisonous doses of arsenic produce violent gastro-intestinal inflammation. The patient complains of pain in the œsophagus and abdomen, inability to swallow, and a feeling of constriction of the fauces. Excessive vomiting and purging ensue; the stools become profuse, serous in character, and closely resemble the rice-water passages of Asiatic cholera. The mucous membrane is stripped off the bowels and appears in the dejecta in shreds. On the third day, providing death has not occurred, various inflammatory conditions of the skin may be noticed, and a remission of all the symptoms takes place. The remission is followed in a few hours by a return of these symptoms, usually more aggravated than at first. Violent cramps occur, especially in the calves. The patient occasionally recovers, but usually passes into collapse and coma, which is followed by death on about the sixth day. The treatment of acute poisoning consists in giving emetics if seen early (apomorphine $\frac{1}{10}$ grain (0.005 Gm.) hypodermically), or in using the stomach-tube. The best chemical antidote is the *ferri oxidum hydratum cum magnesia*, as it not only antidotes the arsenic, but at the same time purges. If this antidote is inaccessible, any ferric solution may be diluted with an equal quantity of water, and ferric hydrate be precipitated by the addition of diluted water of ammonia. If made in this manner, it should be strained and the precipitate washed with pure water until the odor of ammonia has entirely disappeared. As the antidote is not poisonous, a large quantity may be given—as much as an ounce every few minutes if deemed advisable. Opium and demulcent drinks (milk, mucilage of acacia, or emulsion of almonds) may be used to relieve the pain. Body heat is to be maintained by the application of external heat, and circulatory and respiratory stimulants (digitalis, strychnine, or caffeine) are to be used if indicated. If collapse occurs, small doses of atropine will be of use. Large quantities of water are to be administered, to dilute the poison, to aid in its elimination, and to prevent as far as possible irritation of the kidneys.

Chronic arsenical poisoning presents a wide range of symptoms, the most common being as follows: asthma, resulting from irritation of the bronchial mucous membrane; multiple neuritis, producing symptoms resembling those of tabes dorsalis; pigmentation and irritation of the deeper layers of the skin; areas of anæsthesia; muscular atrophy and localized motor palsies, usually confined to the toes. It is treated by the removal of the patient from exposure to the drug, by the administration of potassium iodide to aid in elimination, suitable tonics to improve the general nutrition, and the application of electricity to combat the muscular atrophy.

The dose of arsenic trioxide is stated to be from $\frac{1}{30}$ to $\frac{1}{15}$ of a grain (0.002–0.004 Gm.). It should be given in gradually increasing doses until its physiological effects are observed or the symptoms of the disease for which it is employed are ameliorated. If given upon an empty stomach, it may produce gastric irritation.

ARSENUM.—Arsenic.

Arsenium, Arsenicum.—Arsenic, Fr.; *Arsen, Arsenik*, G.

Symbol, As. Atomicity trivalent and quinquivalent. Atomic weight, 74.4.

Origin.—Arsenic, which is classed by some chemists with the metals, by others with the non-metallic elements, is widely diffused in nature, but is found usually in small quantities. It exists in the uncombined state as *native arsenic*, known also under the name of *cobaltum* or *flystone*, but more frequently in combination with sulphur and sulphides, as *red orpiment* or *realgar*, As_2S_2; *yellow orpiment*, As_2S_3; *arsenical pyrites* or *mispickel*, $FeS_2.FeAs_2$; *cobalt-glance*, $CoS_2.CoAs_2$; *tin-white cobalt*, $CoAs_2$; and in other minerals. It was first obtained in the metallic state by Albertus Magnus in the thirteenth century, by heating together white arsenic and soap.

Preparation.—On heating arsenical pyrites in earthen cylinders most of the arsenic volatilizes and is collected in iron receivers, where it congeals. $FeS_2.FeAs_2$ yields $2As + 2FeS$. A portion of the arsenic remains behind with the iron sulphide, and may be recovered as arsenous acid by roasting. The crude metallic arsenic should be purified by mixing it with charcoal and subliming at the heat of a sand-bath. It is obtained on a small scale by mixing arsenous acid with half its weight of powdered charcoal, introducing the mixture into a crucible, covering it with a layer of granular charcoal 2 or 3 inches thick, and cementing over the crucible in an inverted position another one having a small hole drilled through the bottom; on heating the crucible the arsenous acid is reduced to arsenic, which sublimes, carbon monoxide escaping; $As_2O_3 + 3C$ yields $As_2 + 3CO$.

Properties.—It is a brittle, steel-gray, crystalline mass having a bright metallic luster, gradually changing on exposure to the air to a grayish-black color devoid of gloss. Its specific gravity is 5.73 to 5.96. Heated in a sealed tube, it fuses, but if heated in the open air it volatilizes, without melting, at a temperature of 180° C. (356° F.), a portion of it being oxidized to arsenous acid. Its vapor is colorless, has an unpleasant, garlic-like odor, and between 560° and 860° C. (1040°–1580° F.) possesses a density which shows that the molecule of arsenic contains 4 atoms. On suddenly cooling the vapor in the absence of light and air a yellow modification of arsenic is obtained, which is soluble in carbon disulphide and in strong light quickly reverts to ordinary arsenic. On immersing the metal in water, the air dissolved in the latter oxidizes a portion to arsenous oxide, which explains the use of cobaltum as a fly-poison. Metallic arsenic is insoluble in simple solvents, but dissolves on heating in some fixed oils, and unites readily with most of the metals, with sulphur, chlorine, iodine, and other elements. Hydrochloric acid scarcely affects arsenic, but nitric acid readily dissolves it, oxidizing it to arsenous or arsenic acid.

For action and uses, see ARSENI TRIOXIDUM.

Compounds of Arsenic.—HYDROGEN ARSENIDE or ARSINE, AsH_3, is a colorless gas with a garlic-like odor and the density 2.695, and when ignited burns with a bluish flame, yielding water and arsenous oxide; but on cooling the flame, by holding in it a piece of porcelain or glass, metallic arsenic is deposited. Arsenous hydride is generated whenever compounds of arsenic, especially the oxide, are present in a solution where nascent hydrogen is being generated. Marsh's test depends on this fact (see page 32). A solid hydride is also known, As_4H_2, which is brown. As_2H_4, which corresponds to the liquid phosphorus compound P_2H_4, is not known in the free state, but the methyl derivative $As_2(CH_3)_4$ is known, and is called *cacodyl* because of its disgusting odor.

OXIDES.—Arsenic when burned or roasted in the air forms the trioxide, As_2O_3. When this is oxidized with nitric acid, the solution evaporated to dryness, and the mass heated to low red heat, the pentoxide, As_2O_5, is left as a white mass which melts and decomposes at a higher heat into the arsenous oxide and oxygen. In damp air or in contact with water it deliquesces to an oily-looking liquid, which is a concentrated solution of *arsenic acid*, H_3AsO_4. This is poisonous, however, in a less degree than arsenous oxide; the concentrated solution is corrosive. It is much employed in the manufacture of certain aniline colors and for other purposes in the arts. *Pyro-arsenic* and *meta-arsenic acids* are analogous to the corresponding phosphoric acids, but on dissolving in water yield at once the above *ortho-arsenic acid*.

ARSENOUS CHLORIDE, $AsCl_3$, is a colorless, oily, very poisonous liquid, which has the specific gravity 2.205, boils at 134° C. (273.2° F.), and is decomposed by water into HCl and As_2O_3 (see LIQUOR ACIDI ARSENOSI).

ARSENOUS BROMIDE, $AsBr_3$, is formed from the two elements in the presence of carbon disulphide, like the iodide. It is colorless, crystalline, of a peculiar odor, has the density 3.86, melts at about 20° C. (68° F.), and boils at 202° C. (428° F.). It is deliquescent, and decomposed by water into As_2O_3 and HBr.

Three sulphides of arsenic are known, but the pentasulphide, As_2S_5, is of no practical importance.

Realgar or Red Orpiment, As_2S_2, is a mineral which consists of handsome orange-red scales. It is made by fusing together 5 parts of arsenous acid and 3 parts of sulphur, when sulphur dioxide is given off. It burns with a blue flame, but with a white flame when mixed with potassium nitrate; a mixture for fireworks and signal-lights consists of: red orpiment, 2 parts; sulphur, 7 parts; potassium nitrate, 24 to 26 parts.

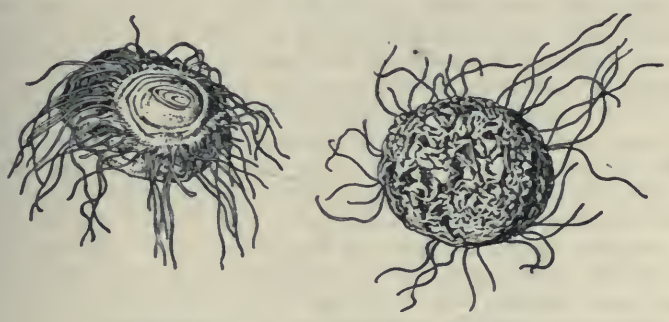
Orpiment, King's Yellow, or Auripigmentum, As_2S_3, is likewise a mineral, crystallizes in prisms or scales, and is artificially obtained by fusing together 5 parts of arsenous acid with 4 to 5 parts of sulphur. It was formerly much employed as a pigment; at present it is used in fireworks, and occasionally, mixed with considerable lime, as a depilatory.

ARUM.

This name has been applied to a number of plants of different genera in the family *Araceæ*. As commonly applied, it refers to the corm of *Arisæma triphyllum* (L.) Torr. (*Arum t.* L.), the American arum, and that of *Arum maculatum* L., the European arum. The former plant is very common in eastern North America, where it is known as *Indian turnip, Wild turnip, Jack-in-the-pulpit, Devil's ear, Pepper turnip, Wake-robin*, etc. It grows in rich soil, especially in moist places, to a height of from 0.3 to 1 M. (1 to 3 Ft.), has 1 or 2 long-petioled, broad, trifoliolate leaves, a green spathe, broadly striped with brown-purple, which arches over and encloses the spadix, the latter 5 to 8 Cm. (2 or 3 In.) in length and as thick as a small lead-pencil.

The corm is nearly lenticular in shape, 1.25 to 5 Cm. (½ to 2 In.) broad and about half as high, depressed in the summit, whence arise the stem and numerous coarse wavy roots, and coarsely reticulate-wrinkled on the evenly rounded brownish lower surface. Applied to the tongue, it is painfully and persistently acrid when fresh, losing this property when cooked or partially when dried. For market, it is transversely sliced and dried. These slices appear as nearly white circular disks with brownish edges, but little shrunken on the faces and of a starchy fracture. They are somewhat acrid.

Fig. 43.



American arum: upper and lower surfaces (½ Nat.).

The European arum plant is commonly known as *Spotted arum, Cocky-baby* or *Cuckoo-babies, Adder's-root, Bobbins, Friar's-cowl, Kings-and-queens, Bloody-man's-finger, Parson-and-clerk, Quakers, Pfaffenpint, Gefleckter Aronstab, Aronwurzel, Zehewurzel, Gouet, Pied-de-veau*, etc. The corm closely resembles the other, except that it is thicker in proportion to its breadth and generally larger, and that its roots proceed from the under surface. It is prepared in the same way and the slices are of similar appearance. If, however, one of the top slices be selected, the stem-depression is not found surrounded by the root-scars, as in the American species. Its composition is practically the same, if not identical.

Arum contains a volatile acrid principle, soluble in ether, much starch, gum, sugar, resin, fat, and numerous needle-shaped crystals of calcium oxalate. Enz claims to have obtained saponin, and Bird thinks there is a volatile alkaloid.

Action and Uses.—In the fresh state arum has an acrid, burning taste and acts as a severe irritant to mucous membranes with which it comes in contact. If given internally, it causes severe gastro-enteritis. The juice of the fresh plant when applied to the skin may even vesicate. The acrid principle is dissipated by drying or by heat, and the partially dried drug may be employed in doses of 10 grains (0.60 Gm.), 3 times daily, in

the treatment of chronic bronchitis, asthma, flatulent colic, and rheumatism. The juice of the fresh plant when incorporated with lard has been applied locally in the treatment of ringworm.

Other Arums.—The *Dragon arum* of the ancients was probably *Amorphophallus campanulatus* Bl., of the East Indies. Italian arum of southern Europe is from *A. Italicum* Mill. That of Asia Minor, with similar properties, is *A. dioscoridis* Sibth. et Sm. The *Pwan-hia* or *Sang-pwan-hia* of Asia is from *A. macrourum* Bunge. The arrow poison *Maschi* of Guiana, is supposed to come from a species of *Arum*.

ASAFŒTIDA, *U. S.*—Asafetida.

Asefétide, Assa fetida, Cibus Deorum, Stercus diaboli, E.; *Stinkasant, Teufelsdreck*, G.; *Asa fœtida*, Fr. and others; *Hing*, India; *Angusa-kema*, Afgh.

A gum-resin obtained from the rhizome of *Ferula fœtida* (Bunge) Regel (*Scorodosma f.* Bunge; *Ferula Scorodosma* B. et T.; *Ferula Narthex* W.—Fam. *Umbelliferæ*), and probably from other species of *Ferula*. Other species which are named by various pharmacopœias as sources of asafetida are *F. alliacea* Boiss.; *F. Asa fœtida* L. (*Asa fœtida Disgunensis* Kaempf.); *F. Narthex* Boiss. (*Narthex Asa fœtida* Falc.).

Asafetida is official in all pharmacopœias. The British and some others say "and probably some other species" than those named in their respective definitions, a wise provision, since it is pretty certain that several species yield it. In the *Pharm. Jour. and Trans.*, Ser. iii., 19: 21, 41, and 365, Mr. E. M. Holmes gives the most extensive and carefully digested account of the asafetida plants which has appeared, and he names the following as at least possible sources of the drug, in addition to those named above: *F. fœtidissima* Regel et Schmal, of Turkestan; *F. alliacea* Boiss.; *F. rubricaulis* Boiss.; *F. teterrima* Karel and Kiril; and *F. persica* W.

Origin.—The asafetida plants are natives of eastern Persia and western Afghanistan, and the principal point of export is Herat. It appears very probable that the product from different localities is obtained from different species, since the composition, even when pure, shows perceptible variations. The account furnished by Dr. J. E. F. Aitchison, who visited the Afghanistan deserts in 1885, of the plants and the method of collecting and preparing the asafœtida for market, may be taken as agreeing in the main with those of several other travellers who have furnished imperfect descriptions. He states that the plains are perfectly barren during the dry season, though a sea of vegetation quickly springs up from the perennial root-stocks of a number of umbelliferous plants, chiefly species of *Ferula* and *Dorema*, immediately upon the commencement of the rains. The immense interlacing leaves are 3 feet or more in length and almost as broad, while the flower-stems reach a height of from 6 to 12 feet, the growth being so dense as to seriously impede travel. At the season's close, this entire growth withers and disappears with surprising rapidity. The principal, if not the only asafetida-yielding species of that region appears to be *F. fœtida*. Only about 1 per cent. of the plants flower in any one season, the process commencing with the production of a large cabbage-like bud. These flowering plants are unfit for the collection of the drug, and the natives, who do not recognize them as being of the same species, eat the tender portions of the underground stem. The root-stock of the others is laid bare to a depth of a couple of inches and a slice cut from the top. A quantity of milky juice exudes, but is not at once collected. The exposed part is then covered by a domed structure, a few inches high, called a *khora*, formed of twigs and covered with clay, leaving an opening toward the north, thus protecting the exposed rhizome from the rays of the sun. The drug-collectors return after 5 or 6 weeks. A thick, gummy, not milky, reddish substance now appears, in more or less irregular lumps, upon the exposed surface, looking exactly like the ordinary asafetida of commerce, and is scraped off or removed along with a slice of the root, and placed at once in leather bags and conveyed to Herat, where it usually undergoes a process of adulteration with a red clay, *tawah*, and where it is sold to export traders, called *Kakri-log*, who convey it to India. We have it upon the authority of Kaempfer that plants under 4 years of age are not productive. A single plant produces a variable amount, according to size and other conditions, ranging from ½ ounce to 2 pounds. The rhizomes sometimes reach the thickness of a man's leg. The fruit is also said to be highly prized for its medicinal properties and is considerably used in India.

The very fine variety of tear asafetida which occurs in the Indian bazars under the

name of *Kandoharee hing* is said by Kaempfer to be obtained from the central portion of the rhizome.

Description.—Asafetida consists essentially of tears, occurring either (the "tear" form) separately or more or less agglutinated, or (the "lump" form) imbedded in a more or less soft and pasty, or, if adulterated, hard and earthy, matrix. The tears vary in size from 0.6 to 2.5 Cm. (¼ to about 1 In.) in diameter and are of irregular form, usually flattened, externally of a yellowish or reddish-brown color, internally whitish and shining, and changing upon exposure by fracture, first to pink, then red, finally to a yellow or brown much like the external color. Tears which exhibit a dingy-brown fracture are of little value. The fracture is toughish. The matrix of the lump form is of a variable shade of brown, usually made reddish by the foreign admixture. The odor is strongly garlicky and very penetrating and persistent, and, according to Kaempfer, is many times stronger in the fresh juice. The taste is persistently bitter and acrid. Asafetida is softened, but not melted by heat, and burns readily and even explosively. It yields a milky emulsion, which becomes yellowish on the addition of ammonia-water. Not less than 50 per cent. should dissolve in alcohol. The ash should not exceed 10 per cent. An understanding of the tests for identity and purity, and of standards of quality, is dependent upon the processes of collection and adulteration, which will be considered farther on.

Adulteration.—Adulteration has been practised upon a most extensive scale and in a variety of forms. The adulterants may be grouped under 4 principal heads: (*a*) the tissue substance of the plant itself; (*b*) other gums produced in the same locality; (*c*) earthy substances; (*d*) turpentine-products. Those of the first class are, of course, insoluble in alcohol, and are to be found in the residue after the use of this solvent, but do not materially increase the yield of ash. Those of the second class have not been investigated, nor have we any precise methods for determining them. Those of the third class represent by far the greater bulk, and are to be determined by the alcohol-insoluble residue, or chiefly by incineration. From 1 to 2 per cent. of ash is a normal constituent of even the purest tear asafetida, partly a natural constituent and partly unavoidable impurity. An allowance of 5 per cent. of ash is ample for a fairly pure article, but different amounts, up to 10 per cent., are allowed by the different pharmacopœias. The best commercial samples of the United States market rarely reach this standard. Our commercial asafetida contains usually from 20 to 40 per cent., frequently more, of ash. It even appears that such matter is sometimes added even after the drug reaches Europe. Importations from Sweden into Hamburg have been reported which consisted almost exclusively of pieces of gypsum thinly coated with asafetida, the latter amounting to not more than 5 per cent. Earthy adulterations consist chiefly of chalky matters, as is indicated by effervescence with hydrochloric or nitric acid.

Tests for the relative quality of asafetida have been confined chiefly to the determination of the alcohol-soluble portion, which, in the best tear forms, reaches to 76 per cent., and which, in a good commercial sample, should reach 60 per cent., as required by the pharmacopœia. Here again, however, we find such a grade of the drug practically wanting in our market, the amount falling frequently to about 10 per cent. The best method of treating this situation has given rise to wide discussion. The claim that adulteration at the point of production is necessary to facilitate transportation, appears to be disposed of by the statement of Aitchison, that the drug is transported over the most difficult part of its journey before the adulteration occurs, as well as by the frequent occurrence of lots not so adulterated. In any case, we may consider an article yielding 60 per cent. of alcohol-soluble matter as easily producible. A more reasonable claim is that the methods of producing asafetida are not subject to our control by means of any regulations or requirements which we may impose. While it might be assumed that the persistent rejection of an adulterated article would result in reforming the collectors' methods, there appears to be no tendency in this direction, notwithstanding that the exportation, presumably due in great part to adulteration, is said to have declined from 500,000 pounds to about $\frac{1}{10}$ of that amount (?). Upon these considerations is based the claim that to continue our requirements under the 60 per cent. standard will result merely in cutting off our supplies, and that this standard should be lowered. The proposition to omit all official standards for the crude article, leaving this subject to be dealt with by the importer and the manufacturer, and substituting for crude asafetida an alcoholic extract, which apparently meets all pharmaceutical and therapeutical requirements, provides only a partial remedy. In view of the enormous distances through which the article is transported and the great cost of a part of this transportation, the wastefulness of these additions and the greatly increased cost to the consumer are seen to be sufficiently serious to demand at least some efforts looking toward reform.

Lloyd suggests that the fourth class of adulterants should be estimated by the determination of the acid number, but admits that present methods do not render this perfectly practicable, since the acid number for the tear asafetida averages about ½ greater than that for the cake form.

It is assumed that the United States Customs officials will exclude importations of grossly adulterated articles, but it is claimed by the Treasury Department that, owing to the fact that they appoint competent and trustworthy officials only at the larger ports of entry, such action is impracticable.

Constituents.—Pure asafetida is essentially an oleo-gum-resin, and should contain 6–9 per cent. of light-yellow volatile oil, to which its odor is due, 60–70 per cent. of resin, and 20–30 per cent. of gum. Besides this, there have been found 0.06 per cent. of vanillin, 1 per cent. of free ferulaic acid, a fraction of 1 per cent. of free asaresinotannol, and formic, acetic, valerianic, and malic acids. The resin is a red-brown amorphous ferulaic ester of asaresino-tannol ($C_{24}H_{35}O_5$), which yields umbelliferon ($C_9H_6O_3$) on dry distillation or by the action of sulphuric acid, and resorcin on fusion with potassium hydroxide. Ferulaic acid ($C_{10}H_{10}O_4$) crystallizes in odorless, tasteless, iridescent needles, soluble in boiling water and alkalies, and yielding, when fused with potassium hydroxide, acetic, oxalic, and protocatechuic acids. It is chemically related to vanillin, eugenol, and cinnamic acid.

It has been claimed by Dieterich that the cake form contains a larger percentage of volatile oil, other things being equal, and is, therefore, superior to the tears. While this may be true for a pure grade of the cake, it is also true that the latter is far more subject to adulteration, and that a degree of purity equalling that of the tears is upon the whole not to be looked for.

Pharmaceutical Preparations.—Emulsion (Mixture) of Asafetida, U. S. P.; Pill of Asafetida, U. S. P.; Tincture of Asafetida, U. S. P.

Action and Uses.—Asafetida has been employed as a stimulating expectorant, an antispasmodic, and as a carminative affecting principally the lower bowel. To it have also been ascribed emmenagogue, laxative, and anthelmintic properties. Its therapeutic value depends principally upon its volatile oil, which is rapidly absorbed. It is eliminated by all the secretions and by the breath. The drug probably increases peristalsis and promotes digestion, for which latter purpose it has been employed as a condiment in India and Persia.

Asafetida may be given with benefit in the tympanites of children dependent upon the various intestinal troubles peculiar to them. Tympanites of enteric fever and hysteria is frequently relieved by this drug when it is given by enema in the form of an emulsion. Hypochondriasis and hysteria may be benefited, but it is probable that the mental effect produced by its disagreeable odor and taste exceeds any real therapeutic value which the drug possesses. In the chronic constipation of the aged attended with flatulence asafetida is a most valuable remedy when combined with other laxatives. It has been employed in whooping-cough, chronic bronchitis, and the nervous irritability of children.

Asafetida is usually given in the dose of from 3 to 10 grains (0.20–0.60 Gm.). It is most commonly administered in the form of a pill or an emulsion. A tincture is sometimes employed.

ASARUM.—Wild Ginger; Canada Snake-root.

False colt's-foot or Colt's foot, Snake-root, Colic-root, Indian ginger, Heart snake-root, E.; *Canadische Schlangenwurzel, Indischer Ingwer,* G.; *Asaret,* Fr.; *Azaro,* Sp.

The dried rhizome and roots of *Asarum Canadense* L. (Fam. *Aristolochiaceæ*).

Origin.—This plant grows in greatest abundance in rich, especially rocky woodlands throughout eastern North America, as far south as the Carolinas. The creeping rhizome sends up a very short stem, at the summit of which are 2 broad, reniform, petioled leaves, with a single brown-purple, nodding, 3-parted flower in the fork. Recently, it has been learned that another species (*A. reflexum* Bicknell) has been confused with it, and has doubtless contributed a certain portion of the drug, though a small portion, as it is much less abundant. It may be distinguished by its reflexed perianth-segments. The odor of this rhizome is quite different from that of the genuine.

Description.—From 7 to 15 Cm. (3 to 6 In.) long and about 3 Mm. (⅛ In.) thick, somewhat bent and curved, with few branches and few thin, nearly simple roots, which are 5 to 7 Cm. (2 to 3 In.) long; nodes often presenting a pointed appearance from the remains of the petioles; externally deep purple-brown, internally whitish, the bark occupying about ⅛ of the diameter and containing the oil-cells, the wood in about 12 small wedge-shaped bundles, forming an interrupted circle and enclosing a large pith; odor aromatic, taste pungent and bitter.

Fig. 44.

Asarum (Nat.).

Constituents.—Asarum contains 2 or 3 per cent. of a yellowish or greenish-amber volatile oil, starch, gum, fixed oil, a neutral resin of agreeable odor and pungent, warm, lasting taste, and *asarin*, a yellow coloring-matter, turned dark-green by ferric salts, but not precipitated by tannin. *Asarone* ($C_{20}H_{26}O_5$), in odorless tasteless crystals which volatilize with irritating vapors, occurs only in *A. Europæum* L., but is replaced in *A. Canadense* by *asarol* ($C_{10}H_{18}O$), a fragrant body. A minute quantity of substance was found giving precipitates with most of the group-reagents for alkaloids.

Pharmaceutical Preparation.—Compound Syrup of Asarum, N. F.

Action and Uses.—Canada snake-root is a feeble remedy possessing tonic, aromatic, and slight diuretic properties. Overdoses sometimes occasion an erythematous or vesicular eruption on the skin, but do not produce nausea or vomiting. It has been employed as a substitute for serpentaria, and may be given in conjunction with other tonics during convalescence from the acute febrile infections.

The powdered drug may be given in the dose of from 15 to 30 grains (1–2 Gm.), or an infusion containing ½ ounce (16 Cc.) to the pint (480 Cc.) of boiling water may be used in doses of from 1 to 4 ounces (30–120 Cc.).

Other Species.—The genus comprises a dozen or more species, half of them Japanese, most of the remainder North American. All are aromatic bitters, like ours, but one or two are known to have more active properties. *A. Europæum* L., *Hazelwort* (*Haselwurz*), *Wild nard* (*Wilder nard*), *Cabaret*, *Asarabacca*, *Foalfoot*, or *European snake-root*, is sufficiently active to be highly sternutatory and actively emetic, and is used as an emmenagogue and in dropsy, while *A. albivenium* Riegel (*Heterotropa asaroides* Morr. et Decne), the *Si-sin* (Jap.), or *Sai-san* (Chin.), of eastern Asia, is used as a hydragogue cathartic and diuretic, as is the *A. Sieboldii* Miq., the *To-sai-shin* of Japan.

ASCLEPIADACEÆ.—The Milk-weed Family.

Genera more than 200, species nearly 1500, very abundant in the tropics, quite a large number extending into temperate regions. The plants produce an abundant milky juice, have mostly opposite, exstipulate leaves, and are distinguished from the *Apocynaceæ* by the absence of the annular stigma and the possession of a peculiar appendage called the "crown," almost infinitely varied, and affording the chief characteristics supporting the systems of classification.

The important constituents are caoutchouc, rendering some of them (see Elastica) rubber-producers, and a peculiar class, chiefly amorphous, some glucosidal, a very few alkaloidal, and some amaroidal, *asclepiadin* (see Asclepias) being the most widely distributed and in a general way typical of a majority of the others.

Properties.—Very many of the milk-juices are more or less poisonous, though those of *Sarcostemma viminale* R. Br. and *Gymnema lactiferum* R. Br., both of the East Indies, are said to be used like cows' milk. Cooking appears usually to destroy these poisonous properties, and the young shoots of *Sarcostemma stipitaceum* R. Br. and *S. Forskalianum* R. et S., both of Arabia, *Asclepias Syriaca* L., of the United States, and the herbage of *Oxystelma esculentum* R. Br., of New Holland, are used as potherbs. A very few edible fruits are produced by the

family, notably the *Moonga* of Beloochistan, from *Mastostigma varians* Stocks. Blue coloring-matters are very common, so that some of the plants (*Gymnema tingens* Spr., *Pergularia bifida* Zipp., etc.) have been utilized as indigo substitutes.

The *Asclepiadaceæ* frequently act as counterirritants, or internally as stomachics, carminatives, or antispasmodics of the stimulating class, occasionally diuretics, though more commonly closely resembling Ipecac in their action, thus nauseating diaphoretics and expectorants (or anti-asthmatics), emetics or purgatives, occasionally anthelmintics.

Arrow poisons are said to be yielded by the juices of *Gonolobus macrophyllus* Mich. and *G. obliquus* R. Br., both of North America. A curare-like principle (*sarcolobin*) exists in *Sarcolobus Spanoghei* Miq., of Java. *Periploca Græca* L., the *Silk-vine* or *Climbing dogs' bane* of the Mediterranean region, contains the heart-poisonous glucoside *periplocin*, and the roots of several other species of this genus are known to be poisonous. *Morrenia brachystephana* Griseb., of the Argentine, is believed to contain an alkaloid, *morresine*.

Ipecac-like properties pertain to the following: The roots of *Sarcostemma glaucum* H. et B., of Colombia, *Cynanchum fuscatum* Link, of southern Europe, many species of *Hoya* of tropical America, also used as fish poisons, and of *Dischidia* of the East Indies. *Barjonia racemosa* Decne, of the Mediterranean region, the *Chanik-el-kilab* of the Arabians, *Vincetoxicum officinale* Moench, the *Lorenzkraut* or *Hundswürger* of middle Europe, which contains *vincetoxin* and is used in the treatment of dropsy, *Gomphocarpus crispus* R. Br., of the Cape, also used as a purgative, *Camptocarpus Mauritanicus* Decne, *Secamone emetica* R. Br., of the East Indies, and the roots of *S. emetica* R. Br., of the East Indies, are also emetics. The following are used as purgatives: both leaves and flowers of *Solenostemma Arghel* Hayne, of Egypt, the leaves of *Gomphocarpus fruticosus* R. Br., of Syria, the milk-juices of *Cynanchum monspeliacum* L., of South America, and *C. acutum* L., of southern Europe, containing *cynanchol*, *cynanchocerin*, and *cynanchin* (*Jahrb. f. Ph.*, 1876, 471, and 1876, 124), and the milk-juices of *Oxystelma alpina* R. Br., of Africa, and of *Leptadenia reticulata* Wight, of Ceylon.

The root of *Chlorocodon Whitei* Hook., of South Africa, contains a principle believed to be cumarin.

The following are commercial articles, requiring special mention:

Calotropis R. Br. is associated in the most important ways with the religious and resulting medicinal superstitions of the Orientals, and is found serviceable, and considerably used, in modern medicine, especially in India. Two species are in use, namely, *C. gigantea* R. Br., the *Gigantic swallow-wort*, *Milk-weed*, or *Silk-weed*, and *C. procera* R. Br., the more important, *Madar*, *Ak*, *Akra*, *Akanda*, etc. All parts of the plants are in native use, but the important products are the root-barks, which resemble condurango in form and appearance, but have the peculiar gray-yellow color of angustura. The odor is characteristic; the taste first bitter, then acrid and strongly mucilaginous. These barks contain caoutchouc, resinous constituents similar to those of gutta-percha, and peculiar bitter substances. Preparations of Calotropis are used for the poisoning of infants and for the production of abortions, both internally and locally applied.

Tylophora asthmatica W. et A. is the *Jangli-pikwán*, *Antamúl*, *Berri-pala*, etc., of India. Its root and powdered leaves are considerably used in India, both by physicians and the laity, as a substitute for Ipecac. The leaves contain *tylophorine*, a crystalline alkaloid, soluble in alcohol and water, reddish, then green and indigo, with sulphuric acid. This has been experimentally shown to be the emetic and purgative principle. The roots of *T. fasciculata* Ham. have been found actively poisonous, with the throat dry, then moist, dizziness, partial paralysis of the extremities, and death with the right heart full, the left empty. Cooking in food did not destroy the activity. These roots are found to contain an amorphous alkaloid, reddish, then carmine and purple with sulphuric acid.

Dœmia extensa Br., the *Utran*, *Sagovani*, *Kuntiga*, etc., of India, has properties very similar to those of our pleurisy root, though rather more active, and anthelmintic. The leaves, which are used, exhale a disagreeable, mousey odor and contain the alkaloid *dœmine*, presenting some similarities to nicotine, and apparently also contained in the roots.

Hemidesmus Indicus Br., the *Anantamúl*, *Sogade*, etc., yields the root known as *Indian sarsaparilla*, used as a sarsaparilla substitute, and containing cumarin.

Gymnema silvestris Br., the Indian *Mera-singi*, *Kavali*, etc., possesses the curious property of destroying the sense of taste for sweetness and bitterness, though for nothing else. It would appear as though this property might be utilized in important ways. It is due to the constituent *gymnemic acid* ($C_{32}H_{55}O_{12}$), a glucoside somewhat resembling glycyrrhizic acid, soluble in both alcohol and water, and forming insoluble salts with alkaloids.

ASCLEPIAS.—Pleurisy Root.

Butterfly-weed, *Orange or yellow milk-weed*, *Orange-root*, *Orange swallow-wort*, *Indian posy*, *White-root*, E.; *Knollige Schwalbenwurzel*, G.; *Asclepiade Tubereuse*, Fr.

The dried root of *Asclepias tuberosa* L. (Fam. *Asclepiadaceæ*).

Origin.—From a perennial hairy herb with (mostly clustered) ascending, very leafy stems, and handsome orange-colored flowers, common in sandy soil thoughout North America, from Ontario south, except in the far West, the root usually deeply buried.

Description.—Irregularly or interruptedly fusiform, 10 to 20 Cm. (4 to 8 In.) long, 1 to 2 Cm. (½ to 1 In.), rarely more, in thickness, usually cut transversely or longitudinally into irregular pieces; externally light orange-brown, becoming gray on keeping, coarsely annular at the crown, bearing numerous fine longitudinal and transverse furrows, imparting a finely tuberculate appearance and feeling; fracture tough, uneven, granular, whitish, the thin bark

Fig. 45.

Fig. 46.

Asclepias (½ Nat.).

yellowish in the outer layer, the wood-bundles pale-yellow; almost inodorous, taste bitterish, slightly acrid, and nauseous.

A. decumbens L., of the central and southern States, may be distinct, but no endeavor has been made to distinguish it pharmaceutically. It probably yields a large part of the drug. No other species of the genus has a root much resembling this, nor is there any other drug which can readily be mistaken for it. The detection of possible adulterants of the powder has not been investigated. Adulteration with the roots of other species of the genus would not be serious, as they possess the same general properties.

Constituents.—Besides much starch, tannin, albumin, pectin, gum, fat, a trace of volatile oil, and 2 resins, only 1 ether-soluble (Elam Rhoads), the active constituent appears to be *asclepiadin*, widely distributed in the family, an unstable, amorphous yellowish glucoside, having the taste and activity of the root. It is soluble in ether, alcohol, and hot (difficultly in cold) water, precipitated by tannic acid, not by lead acetate, its yellow color deepened, afterward green or brown (Clabaugh), by concentrated sulphuric acid (Sonn), and pink, then purple, by nitric acid. It yields *asclepin*, which is less active.

Action and Uses.—The root of *Asclepias tuberosa* has been employed as a diuretic and carminative, and in large doses as a cathartic and an emetic.

Because of its diaphoretic properties the drug has been given with asserted success in the forming stages of acute diseases, such as pleurisy and pneumonia. As an expectorant it is recommended in many pulmonary and bronchial affections of a subacute or chronic character. It is claimed that asclepias may be employed with benefit in flatulent colic and indigestion, but in these conditions it is rarely used.

The dose of the powdered root is from 20 to 60 grains (1.3 to 4 Gm.). A decoction made with 50 Gm. of the drug and 1000 Cc. of water may be given in the dose of 2 or 3 fluidounces (60–90 Cc.) every 2 hours.

Other Species.—The genus contains about 80 species, mostly in North America, a few in South America and Africa. The juices of the others are usually much more abundant and milky than in *A. tuberosa*.

A. Syriaca L. (*A. Cornuti* Decne), the *Common milk-weed, Silk-weed*, or *Swallow-wort, Virginia silk, Wild cotton, Seidenpflanze, Asclépiade à la Soie, Herbe à la ouate*, is a tall, stout,

very milky perennial roadside weed of eastern and central North America. Its milk-juice is a domestic application to warts, and attempts have been made to use its seed-hairs as a cotton substitute. Its rhizome and roots are very extensively used like the official, as are those of *A. incarnata* L., the *Swamp milk-weed, Silk-weed,* or *Swallow-wort, White Indian hemp, Water nerve-root, Fleischfarbige,* or *Asclépiade incarnate,* exceedingly common in swamps in the eastern and central United States. *A. pulchra* Ehrh., by many regarded as a variety of the last, from which it is distinguished by its hairiness, the other being nearly smooth, is indiscriminately used under the same names. Another species, both root and herbage very largely used, especially in tropical America, where it grows abundantly, taking the place of our pleurisy root and much resembling it, is *A. Curassavica* L., the *Bastard ipecac, Blood flower, Blood-weed, Red-head, Cancerillo,* or *Ponchishuiz.* Chemical examinations of the three last-named species show them to agree very closely in composition with the official. More than a dozen other species are recorded as being similarly used, and probably the same constituents and properties prevail throughout the genus.

ASPARAGUS.—Asparagus.

Spargel, G.; *Asperge,* Fr.; *Sperage; Esparraguera,* Sp.; *Asparago,* F. It. (*Rhizoma et Turiones*).

Asparagus officinalis, L. (Fam. *Liliaceæ*), the well-known culinary vegetable.

The "turiones" are the young edible shoots. The "radix" or "root" is the rhizome and roots. Both are official in France and are more or less used medicinally.

Description.—Rhizome (which should be collected in the autumn) elongated and much branched, about 2 Cm. (½ In.) thick, somewhat compressed, flexuous, brown or brownish, scaly the upper surface marked with broad stem-scars, the lower bearing numerous yellowish-white fibrous roots; fracture fleshy or gummy; odor none; taste mucilaginous and sweetish.

Constituents.—Fixed oil, dextrose, mannite, gum, phosphates and malates, spargancin, and asparagin occur. *Spargancin* is an orange-red sublimable coloring-matter, soluble in ether, and crystallizing in scales. *Asparagin* (amido-succinamide, $C_4H_8N_2O_3.H_2O$), said to exist only in the shoots, occurs in rhombic prisms, insoluble in alcohol and ether, soluble in 12 parts of water, odorless, of saltish and cooling taste. It unites with acids and alkalies, and on boiling with them yields aspartic acid (amido-succinic acid, $C_4H_7NO_4$) and ammonia. Nitrous acid converts it into malic acid, water, and nitrogen. It is very widely distributed among plants, especially in the *Leguminosæ,* and occurs in convallaria, belladonna leaves, althæa, glycyrrhiza, euonymus, hops, and other drugs. The peculiar offensive odor of the urine after eating asparagus is due to the formation of methyl-mercaptan (Nencki).

Action and Uses.—All parts of the plant, principally the young shoots, seem to possess diuretic properties; increasing chiefly the watery constituent of the urine. The peculiar odor imparted to the urine is due to asparaginic acid It is claimed by some and disputed by others that asparagin in doses of 2 to 5 grains (0.10–0.30 Gm.) depresses the circulation, and produces headache, muscular relaxation, and in some individuals inflammation of the genito-urinary tract. In doses of 1 grain (0 05 Gm.), 3 times a day, asparagin has been employed in the treatment of cardiac dropsy and chronic gout. In these conditions the drug is usually combined with potassium bromide. Fluid-extract of asparagus has also been used with marked benefit in chronic parenchymatous nephritis. The drug is more largely employed in France than elsewhere.

The dose of the fluidextract is 1 to 4 fluidrachms (4–16 Cc.). A syrup, made by dissolving 190 parts of sugar in 100 parts of the juice expressed from the shoots and clarified by heat and filtration, is given in the dose of 1 to 2 fluidounces (30–60 Cc.). A solid extract and tincture have also been employed.

ASPIDIUM, *U. S.*—Male Fern.

Male shield fern, Basket-fern, Knotty or Sweet brake, Bear's-paw root, E.; *Wurmfarn, Waldfarn, Johanniswurzel,* G.; *Stipites Aspidii,* Ph. Nor.; *Fougère mâle,* Fr.; *Helecho Macho,* Sp.; *Feto Macho,* Port.

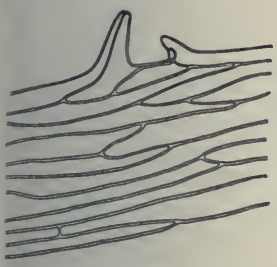
The dried rhizome of *Dryopteris Filix-mas* (L.) Schott (*Polypodium F.* L.; *Aspidium,* F. Sw.; *Lastræa F.* Presl.; *Nephrodium F.* Rich.; *Polystichum F.* Roth.) and of *Dryopteris marginalis* (L.) Asa Gray (Fam. *Filices*).

The synonyms of *D. marginalis* are similar.

Male fern is official in all pharmacopœias, which mostly require autumn-collection and use within a year. The latter requirement is unnecessary, if only the drug with green fracture is accepted.

Origin.—The first-named species is distributed over nearly the whole of the north-temperate zone, extending into the tropics in mountainous regions of both hemispheres. The second occurs in Canada and the United States. Both are tall, handsome ferns, the fronds erect from the slightly ascending ends of horizontal creeping rhizomes, the older portions of which are covered with the stipe-bases. The drug should be collected in the late summer or early autumn.

Fig. 47.



Male fern: section of scale from unpeeled rhizome (much enlarged).

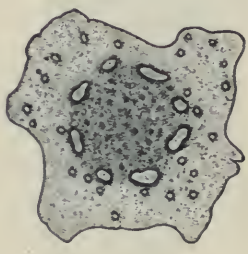
Fig. 48.

Male fern, "finger."

Fig. 49.

Aspidium: surface of peeled rhizome.

Fig. 50.



Dryopteris Filix-mas Schott; transverse section of rhizome.

Description.—Before being peeled, 10 to 15 Cm. (4 to 6 In.) long by 5 to 7 Cm. (2 to 3 In.) thick, including the densely imbricated, dark-brown, cylindraceous, slightly curved stipe-bases and the dense mass of brown, glossy, transparent, soft, chaffy scales; when peeled, 1 to 2 or 3 Cm. ($\frac{2}{3}$ to about 1 In.) thick, slightly curved, cylindraceous, pale-green when first peeled, becoming pale-brown, or, when long kept, rusty-brown, smoothish, or somewhat roughly scarred with remains of the stipe-bases; texture rather spongy, pale-green, with age becoming gradually brown from the outside inward, the *Filix-mas* showing about 10, the *marginale* about 6 steles in a loose and interrupted circle. The marginal hairs of the stipe-scales of *Filix-mas* consist each of two parallel, slender cells, neither of them glandular; those of *marginalis* are almost identical in appearance, being directed slightly more toward the apex of the scale, and their lower cell perhaps a little narrower. Upon the older scales they are nearly wanting.

Male fern has a disagreeable odor and a bitter-sweet, acrid, astringent, and nauseous taste.

The chaff, together with the dead portions of the rhizome and stipes, should be removed, and only such portions used as have retained their internal green color. The powder should be freshly prepared and bright green.

The peeled stipe-bases ("fingers") have almost superseded the rhizome proper in the American market. They are smaller, claw-shaped, and smoothish, with the exception of several blunt longitudinal ridges, separated by coarse furrows.

Male fern is one of the most extensively adulterated of drugs, the rhizomes of many other species of fern having been employed for the purpose. How far the properties of the latter agree with those of the genuine has been scantily investigated. Identification of some of these, in the peeled condition, is extremely difficult, when not actually impossible. For this reason, and because the drug retains its composition and properties for a much longer time when unpeeled, it should be retained in that condition until required for use.

Laurén (*Pharm. Rev.*, May, 1897, 96) relies upon the microscopical detection of the internal glandular structures and intercellular spaces (Fig. 51) in the fundamental tissue of the rhizomes of those species which have been found to be active.

It cannot be too strongly emphasized that the careless or too lengthy preservation of this drug results in certain deterioration. Most of the male fern of the American market at the present time is very small and inferior. It is doubtless due to this extensive adulteration and inferior and deteriorated quality that male fern, naturally one of the most certainly acting of medicines, has come to be regarded as one of the most unreliable.

Constituents.—The rhizome yields 10 per cent. of filixtannic acid, which is changed to filix-red by boiling with water, 19 to 31 per cent. of inactive filicic anhydride (so-called crystalline filicic acid or filicin), and 2 to 4 per cent. of active amorphous filicic

acid, $C_{14}H_{16}O_5$. Boehm (1898) isolated albaspidin, $C_{22}H_{28}O_7$, aspidinol, $C_{12}H_{26}O_4$, aspidinin, and active aspidin, $C_{23}H_{28}O_7$, the proportion of the latter increasing as that of the filicic acid decreased. His many investigations demonstrated the impossibility of one being changed into the other in the process of manufacturing. In preparations of male fern, the active filicic acid is changed into inactive filicic anhydride and deposited as crystals. If these are dissolved in alkali and reprecipitated by acid, they become again active. Pavesi's aspidin is a very impure filicic acid. Aspidium also yields 11 per cent. of uncrystallizable sugar, 0.04 per cent. of ethereal oil, 6 to 7 per cent. of green

Fig. 51.

Male fern: *a*, intercellular secreting cell; *b*, lemon-colored resin; *c*, intercellular space; *d*, starch-grains.

fixed oil composed of the glycerides of filixolic acid and of volatile filosmylic acid, a small quantity of a bitter principle, starch, wax, and 2 resins, one hard and brick-red, the other black and plastic.

Pharmaceutical Preparations.—Oleoresin of Aspidium, U. S. P.; Liquid Extract of Male Fern, Br.

Action and Uses.—Aspidium has been employed from the earliest antiquity as a tænicide. As a rule the drug is not absorbed when ingested, and produces no constitutional symptoms in the patient. If given in overdose or allowed to remain too long in the alimentary canal, grave, or even fatal, symptoms may arise. Poisonous amounts produce severe gastro-enteritis, vomiting, purging, abdominal pain, muscular relaxation, and somnolence. Ultimately convulsive seizures, followed by collapse, coma, and death, may occur. Permanent or temporary blindness with apparently little or no change in the retina sometimes results from an overdose of this drug.

Before employing male fern, it is well to starve the patient from 12 to 24 hours, during which time only small quantities of broth or milk should be administered. The morning following the period of fasting the drug should be given, and in the course of a few hours be followed by a brisk purge, which should not be castor oil, as it aids in the absorption of the drug. It is well to employ in addition a large saline enema after the stool, to insure the removal of any segments which might otherwise be left behind.

Male fern may be given in the dose of 30 to 60 grains (2–4 Gm.).

The oleoresin (U. S.) is usually administered either in emulsion or in capsule in the dose of 15 to 60 minims (1–4 Cc.). Extractum Filicis Liquidum, Br., is given in the dose of 45 to 90 minims (3–6 Cc.).

Other Species (see also *Filices*).—The ethereal extract of *D. spinulosa* (Retz.) Kuntze has been found practically identical with that of male fern. That of *D. Anthamanticum* (Hook.) Kuntze, the *Radix Pennæ* or *R. Uncomocomo* of South Africa, is similarly active and has an extensive native use. It is much larger than male fern, from which it presents distinctive structural characters, but has the same peculiar internal glandular structure.

ASPIDOSPERMA.—Quebracho.

White quebracho, E.; *Quebracho Blanco*, Sp.

The dried bark of *Aspidosperma Quebracho-blanco* Schlechtendal (Fam. *Apocynaceæ*).

Origin.—The Aspidosperma tree reaches a height of from 50 to 90 feet, with a thick trunk and a large crown, and is very ornamental. Its fruit ripens in July. It abounds in the dry central and western districts of the Argentine and adjacent regions. The wood is very valuable for building, as well as for carving and similar purposes. The juice of the green fruit is used like rennet. To what extent the bark and wood are used, like those of red quebracho, for tanning purposes, is very uncertain. Reports of such use are current, but it seems likely that most of them have arisen through confusion of this name with that of red quebracho. The name quebracho, derived from two Spanish words meaning to break an axe, is applied to various trees. In the present instance it is used in allusion, not so much to the wood, however hard and tough, as to the bark, which, on account of its great number of stone-cells, quickly nicks out the edges of any tools used upon it.

FIG. 52.

Aspidosperma (½ Nat.).

Description.—In nearly flat pieces, about 1 to 3 Cm. (⅜ to 1 In.) thick; outer surface yellowish-gray or brownish, deeply fissured; inner surface of a very pale-yellow, coarsely striate; fracture displaying 2 sharply defined strata, of about equal thickness, and both marked with numerous whitish dots and striæ arranged in tangential lines; fracture of the outer rusty-red layer rather coarsely granular, that of the nearly white inner layer very hard, tough, and splintery. Large and very hard groups of stone-cells abound in both layers. Aspidosperma is inodorous, and the taste is very bitter in both layers and slightly aromatic.

Upon soaking the shavings from the inner portion with alcohol, evaporating, boiling with water, and adding ferric chloride, a green and not a brown color should develop (distinction from red quebracho).

This is the largest and coarsest of our official barks, and is not readily to be mistaken for anything else, except the bark of the red quebracho, which is now often sold for it in this country. The presence of the latter is to be suspected when the inner bark fracture displays a red or brown color, and the test appended to the above description will then be found conclusive. Although distinctly bitter in all its parts, it is less so, especially in the inner layer, than the white. So general has been the substitution of the red for the white quebracho, and so little have the distinctions between them been known, that the description heretofore official has been that of a mixture of the two barks. It is not remarkable, under these circumstances, that such a wide discrepancy should exist between the therapeutic reports upon the drug. Grounds are not wanting even for the suspicion that there are two distinct barks known as "red quebracho."

Commercial supplies and therefore the price of the genuine drug are very irregular and uncertain. We have met with no other substitute or adulterant of aspidosperma than the red variety, but have received the outer bark, from which the inner had been removed, perhaps for the manufacture of the alkaloids.

Constituents.—The bark contains a small amount of tannin (3 to 5 per cent.) and the two sugars, quebrachit and inosit. Commercial aspidospermine is mostly a mixture of the alkaloids of this bark, of which 6 are recognized, as follows: aspidospermine, aspidospermatine, aspidosamine, quebrachine, hypoquebrachine, quebrachamine.

The extract, prepared with hot alcohol, is treated with sodium hydroxide and chloroform, the latter solution evaporated, the residue taken up with diluted sulphuric acid, and the filtrate precipitated by sodium hydroxide. On dissolving the mixed alkaloids in a little boiling alcohol, aspidospermine, quebrachine, and quebrachamine will crystallize on cooling,

and are separated by crystallization from diluted hydrochloric acid, aspidospermine remaining in the mother-liquor. The alcoholic mother-liquor contains the remaining bases, which are combined with acetic acid; from this solution ammonia precipitates aspidosamine; aspidospermatine and hypoquebrachine are precipitated by sodium hydroxide and separated by boiling benzin, in which the latter is nearly insoluble. All these alkaloids are more or less soluble in alcohol, ether, and chloroform. *Aspidospermine*, $C_{22}H_{30}N_2O_2$, melts at 205° C. (401° F.), and is a weak base, forming mostly amorphous salts; warm perchloric acid colors the solution permanently deep-red; platinic chloride gives a blue precipitate; sulphuric acid and lead peroxide (or potassium dichromate) color the alkaloid brown, afterward cherry-red or purplish. *Aspidospermatine*, $C_{22}H_{28}N_2O_2$, melts at 162° C. (324° F.), is a strong base, and yields amorphous salts; it is colored, like the preceding, by perchloric acid, but not by sulphuric acid and chromate. *Aspidosamine*, $C_{22}H_{28}N_2O_2$, melts near 100° C. (212° F.), is a strong base, is colored blue by sulphuric acid and dichromate, and gives with boiling perchloric acid a fuchsine-red liquid. *Quebrachine*, $C_{21}H_{26}N_2O_3$, melts at 215° C. (419° F.), yields crystallizable salts, is colored yellow by sunlight, also by warming with perchloric acid, and gives with sulphuric acid a colorless solution becoming blue on standing or more rapidly by adding lead peroxide or potassium dichromate, the color produced by the latter changing to red-brown. *Quebrachamine* resembles the preceding, but melts at 142° C. (228° F.), and is freely soluble in cold alcohol and ether. Hypoquebrachine is yellow, amorphous, melts near 80° C. (176° F.), and gives in solution a cherry-red color with ferric chloride.

Action and Uses.—Aspidosperma exercises a sedative influence upon the respiratory system, for which reason it has been employed in the various forms of dyspnœa. It has no effect upon the circulation except in overdose, when it acts as a depressant. The prolonged use of the drug not uncommonly causes somnolence, vertigo, headache, nausea, and ptyalism.

Quebracho was at one time employed to a limited extent in the treatment of all asthmatic conditions. It is stated by those who have used the drug most that it may act as a palliative in bronchial asthma, but is of little or no service in those forms dependent upon cardiac or renal disease.

It is usually administered in doses of from 15 to 60 minims (1–4 Cc.) of the fluid-extract, or from 1 to 3 grains (0.06–0.20 Gm.) of the extract. The sulphates of aspidospermine and quebrachine have been employed both hypodermically and by the mouth in doses of from 1 to 2 grains (0.06–0.12 Gm.).

ATROPINA, *U. S., Br.*—Atropine.

Atropia, Atropinum.—*Atropia*, E.; *Atropine*, Fr.; *Atropin*, G.

Formula, $C_{17}H_{23}NO_3$. Molecular weight, 287.04.

An alkaloid obtained from Atropa Belladonna and other plants of the same family. As it occurs in commerce it is usually accompanied by a small portion of hyoscyamine, from which it cannot be readily separated.—U. S. An alkaloid, $C_{17}H_{23}NO_3$, obtained from belladonna-leaves or root.—Br.

The pharmacopœias have omitted the processes for the preparation of atropine, as it cannot be economically prepared on a small scale. The alkaloid may be obtained by the following method: The finely powdered drug is exhausted with alcohol and the percolate mixed with calcium hydroxide to decompose the natural salt and liberate the alkaloid, which remains in solution; after filtration, the filtrate is acidulated with diluted sulphuric acid, concentrated to remove alcohol, fat, and resin, and treated with potassium carbonate in excess. (If necessary, the acid liquid, before addition of the alkali, is shaken with chloroform to remove chlorophyll.) The precipitated atropine is removed, washed with water, and dissolved in alcohol; to this alcoholic solution water is added, drop by drop, to incipient turbidity, and the alkaloid allowed to crystallize. Since it has been demonstrated that hyoscyamine is converted into atropine during the process of extraction, it is probable that much of the commercial atropine is prepared from scopolia rhizome. To obtain the alkaloid in a crystalline form, the dried alkaloid should be dissolved in 7–8 parts of absolute alcohol and evaporated at a moderate temperature out of contact with moisture or under a dessicator.

Properties.—Pure atropine occurs as colorless or white, lustrous, acicular needles or prisms, and has a disagreeably bitter and acrid taste. It is soluble at 25° C. (77°

F.) in 450 parts of water, 1.46 parts of alcohol, 16.6 parts of ether, and 1.56 parts of chloroform (U. S.). At 80° C. (176° F.) atropine dissolves in 86.7 parts of water, and at 60° C. (140° F.) in 0.9 part of alcohol (U. S.). The Br. P. gives the solubility of atropine at 15.6° C. (60° F.) as 1 part in 300 of water, while Wormley gives it as 1 in 400, and Allen and Prescott, both, as 1 in 600 parts. Atropine is said to be also soluble in 4.8 parts of an 80 per cent. aqueous solution of chloral hydrate and in about 50 parts of glycerin, also in amyl alcohol, benzene, and olive oil, but only sparingly soluble in petroleum benzin and carbon disulphide. "Pure atropine is optically inactive, being composed of dextro-atropine (dextro = + 10.02°) and lævo-atropine (lævo = — 9.22°), both of whose melting-points are 111° C. (231.8° F.), and the melting-point of whose chloraurates are both 146° C. (294.8 F.). The chloraurate may be made by adding gold chloride test-solution to a solution of atropine in diluted hydrochloric acid, washing, collecting, and drying the precipitate. Pure atropine chloraurate melts at 136° C. (277° F.). Pure hyoscyamine chloraurate melts at 160° C. (320° F.). Pure hyoscine chloraurate melts at 196° to 198° C. (384.8°–388.4° F.). Atropine chloraurate alone melts under boiling water. At about 113.8° C. (237° F.) atropine melts, forming a colorless liquid; the melting-point of atropine (free from hyoscyamine) is about 115.8° C. (240.4° F.). When ignited, it is consumed without leaving a residue."—U. S.

Its salts are mostly insoluble in chloroform and ether. Both of these solvents, however, extract notable quantities of the alkaloid from the solution acidulated with tartaric acid.

It is a strong base, its aqueous solution reacting alkaline to both litmus and phenolphthalein, but in aqueous solution it rapidly undergoes decomposition, acquiring a yellow color and disagreeable odor. It is a powerful mydriatic, 1 part dissolved in 45,000 parts of water will dilate the pupil in 40 minutes to 1 hour. It dissolves without color in concentrated sulphuric or nitric acid.

If a small quantity of atropine or one of its salts be heated with a few Cc. of concentrated sulphuric acid, a peculiar odor, recalling that of a mixture of rose, orange-flower, and melilot, will become noticeable. On now gradually adding minute fragments of potassium dichromate, the odor will change to that of oil of bitter almond (U. S.). Atropine and its salts are decomposed by prolonged contact with sodium or potassium hydroxide, and if heated with either of them, evolve ammonia. On dissolving a small quantity (about 0.1 Gm.) of atropine in 2 Cc. of alcohol, and adding an equal volume of mercuric chloride test-solution, a yellow precipitate, which soon turns red, is produced (Br.). Atropine is easily saponified, or hydrolyzed, by treatment with alkalies or acids. Heated with barium hydroxide, it is hydrolyzed into *tropic acid*, $C_9H_{10}O_3$, and *tropine*, $C_8H_{15}NO$. Atropine has been made synthetically by heating together these two compounds. It is also easily made from hyoscyamine, the latter changing to atropine by contact with sodium hydroxide in alcoholic solution or by keeping hyoscyamine at a temperature of 110°–115° C. (230°–239° F.). According to Einhorn (*Ber.*, 23, 1338–1344), atropine is closely related to cocaine, as evidenced by their respective decomposition-products *tropidine* and *anhydroecgonine*, the latter being the carboxylic acid of the former. It is converted into *apoatropine*, $C_{17}H_{21}NO_2$, or *anhydro-atropine*, by loss of water, by gradually adding the atropine to fuming nitric acid heated to about 50° C. (122° F.), or by simply keeping atropine sulphate in nitric acid of specific gravity 1.38 at ordinary temperatures for 24 hours, or when atropine sulphate or hyoscyamine sulphate is dissolved in concentrated sulphuric acid in the cold and the solution poured into water. A similar result is obtained by the action of acetic and benzoic acids or phosphoric anhydride upon these two alkaloids at 85° C. (185° F.). Apoatropine and *atropamine*, $C_{17}H_{21}NO_2$, are indentical (Hesse and Merck), and both convertible into the alkaloid *belladonnine*, $C_{17}H_{21}NO_2$, by warming with hydrochloric acid. The researches of W. Will, E. Schmidt, and others, clearly indicate the production of atropine from hyoscyamine during the various stages of the extraction and subsequent treatment of the alkaloid in its commercial preparation from belladonna and other sources. From its isomer hyoscyamine, $C_{17}H_{23}NO_3$, it is distinguished principally by its optical inactivity, and the melting-points of the two alkaloids and their aurochloride.

Since Ladenburg effected the synthesis of atropine from tropine and tropic acid (see above) other *tropeines*, or compound esters, have been produced with various organic acids, among the more important of which are—homatropine, $C_{16}H_{21}NO_3$, *oxytoluyl-tropeine*, crystallizable from absolute ether in prisms, which are difficultly soluble in water but soluble in ether and chloroform, melt at 98° C. (208.4° F.), and produce strong mydriatic

action; benzoyl-tropeine, $C_{15}H_{21}NO_3$, a crystallizable base forming salts similar to atropine, and producing strong mydriatic action; atrolactyl-tropeine, $C_{17}H_{23}NO_3$, a strong base similar in action to atropine; others of pronounced basic properties being salicyl-tropeine, cinnamyl-tropeine, phenyl-acetyl-tropeine, and the oxybenzoyl-tropeines.

Atropine readily forms a periodide ($C_{17}H_{23}NO_3.HI.I_3$) when an aqueous 0.5 per cent. solution of atropine acidulated with hydrochloric acid is added to an aqueous solution containing 1 per cent. of iodine and 1.5 per cent. of potassium iodide, forming a dark-brown to black powder, crystallizable from alcohol in dark-green prisms or leaflets, which lose iodine at 90° C. (194° F.) and melt at 140° C. (284° F.).—Prescott and Gordin.

Tests.—In solutions of 1 part in 2500 of water atropine yields yellow crystalline precipitates with picric acid and auric chloride (oily at first), and brownish amorphous precipitates with iodine in potassium iodide, and bromine in hydrobromic acid, the precipitates becoming crystalline after a time. "On adding sulphuric acid to atropine, no color should be produced (absence of readily carbonizable organic impurities), nor should any color be developed upon the subsequent addition of nitric acid (absence of, and difference from, morphine). Platinic chloride test-solution produces no precipitate (difference from most other alkaloids). Gold chloride test-solution yields a yellow, lustreless precipitate. If a few crystals of atropine be placed in a porcelain dish on a water-bath with a few drops of nitric acid, and heated to dryness, a yellow residue will be produced on cooling; if a few drops of alcoholic potassium hydroxide test-solution and a fragment of potassium hydroxide be added, a permanent violet color is produced; hyoscyamine and hyoscine will produce the same color, but the presence of strychnine masks the reaction. If a crystal of atropine be added to a few drops of sulphuric acid containing 1 drop of creosol a pink color should be produced, which is not dissipated by the addition of 0.5 Gm. of hydrated chloral (distinction from other alkaloids, hyoscyamine producing a brown color, strychnine black, and hyoscine, which remains colorless)."—U. S.

The physiological effect—dilating the pupil of the eye—is a most important test, though not characteristic of atropine and its isomers alone. The test should not be made in concentrations greater than 1 part of the alkaloid in 500 parts of distilled water, 1 or 2 drops of the solution being dropped into the eye and the size of the pupil compared with that of the other eye, of the same individual, not so treated. The character of the precipitate with auric chloride (oily drops changing on crystallizing from hot solution to lusterless yellow crystals melting at 135.5°–138° C.) is quite characteristic, also its behavior with mercuric chloride (Gerard's test), in which 0.1 grain of the free alkaloid is placed on a watch-glass or in a test-tube, and 20 minims of a 2 per cent. solution of mercuric chloride in proof spirit gradually added, producing at once a red coloration. Flückiger's test: a minute quantity of the alkaloid is placed on phenolphthalein paper, which is then wetted with strong alcohol. No color is produced at first, but on allowing the alcohol to evaporate, and then touching the alkaloid with a drop of water, a brilliant red coloration appears. On adding alcohol the color is destroyed, but reappears as the alcohol evaporates. Vitali's reaction for atropine is a most important chemical test, as but few alkaloids simulate the *violet color* produced. A small portion of the alkaloid is treated with a little fuming nitric acid, then heated on a water-bath to dryness (a fragrant odor results); the residue, when cooled, is touched with a drop of solution of potassium hydroxide in absolute alcohol, when in presence of atropine, or its isomers, a *violet color* will appear, slowly changing to a dark-red. Strychnine gives a red and brucine a green color under these conditions, but no fragrant odor is developed by these. Further, if the violet-colored residue be evaporated to dryness and touched a second time with a drop of the potassium hydroxide solution, the color is intensified in the case of atropine, while with strychnine, on drying, the color changes to a reddish-yellow. If the residue after the treatment with nitric acid be moistened with a few drops of solution of ammonia in water, a yellow-colored solution results (orange-red in the case of strychnine), which on further treatment with the alcoholic solution of potassium hydroxide turns a violet color (only transiently violet and quickly passing into a blood-red colored solution in the case of strychnine). Modifications of the Vitali test have been made by dissolving the alkaloid in concentrated sulphuric acid and adding a crystal of sodium nitrite (Arnold) or sodium nitrate (Flückiger), and then adding an alcoholic solution of potassium or sodium hydroxide, and thus obtaining the violet color.

For action and uses, see ATROPINÆ SULPHAS.

ATROPINÆ SULPHAS, *U. S.*, *Br.*—Atropine Sulphate.

Atropinum sulfuricum, P. G.; *Sulfas atropinæ*, Fr. Cod.—*Sulphate of atropia*, E.; *Sulfate d'atropine*, Fr.; *Atropinsulfat, Schwefelsaures Atropin*, G.

Formula, $(C_{17}H_{23}NO_3)_2H_2SO_4$. Molecular weight, 671.43.

A white, indistinctly crystalline powder, without odor, having a bitter, nauseating taste, and permanent in the air.—U. S.

Atropine sulphate, $(C_{17}H_{23}NO_3)_2H_2SO_4$, may be obtained by neutralizing atropine with diluted sulphuric acid.—Br.

White, crystalline masses melting at 180° C. (356° F.), prepared from atropine melting at 115.5° C. (240° F.).—G.

Preparation.—Atropine sulphate may be prepared either by adding atropine slowly to a mixture of sulphuric acid and alcohol or by dissolving atropine mixed with water by means of diluted sulphuric acid. In either case a perfectly neutral solution must be obtained, which is then evaporated to dryness at a temperature below 40° C. (104° F.). Some of the commercial salts show an acid reaction when dissolved in water, and are, therefore, unfit for use.

To crystallize the sulphate, M. Laneau directs that 2.89 parts of atropine be dissolved in 4 parts of absolute alcohol with the application of a gentle heat and the solution *neutralized* by the careful addition of a solution of 4 parts of sulphuric acid (specific gravity 1.85) in 3 parts of absolute alcohol, the mixture being constantly stirred. The neutralized solution is then allowed to evaporate spontaneously.

Properties.—Atropine sulphate occurs as a white crystalline powder or microscopical needles and prisms (the form of the latter being probably due to the hyoscyamine present), having a very bitter, nauseating taste and permanent in the air. It should be tasted with the utmost caution, and only in dilute solution. It is soluble at 25° C. (77° F.) in 0.38 part of water, 3.7 parts of alcohol, 2140 parts of ether, and in 620 parts of chloroform.—U. S. The Br. P. gives the solubility at 15.6° C. (60° F.) as 1 part in 1 of water, or 10 parts of 90 per cent. alcohol, and states that the salt is insoluble in ether and chloroform. Soluble in 1 part of water and in 3 parts of alcohol, forming colorless neutral solutions; almost insoluble in chloroform and in ether.—P. G. The salt melts at about 189.9° C. (373.5° F.); when free from hyoscyamine, it melts at about 188° C. (370.4° F.), U. S.; 183° C. (361.4° F.), Br.; 180° C. (356° F.), P. G.. When ignited it chars, emits acrid vapors, and is very rapidly and completely consumed. Its aqueous solution yields a white precipitate with solution of barium chloride which is insoluble in hydrochloric acid.

Tests.—On adding potassium hydroxide test-solution to a solution of atropine sulphate, a white precipitate is obtained, which should respond to the reactions and tests given under ATROPINE.—U. S. It should dissolve without color in sulphuric and nitric acids. To 0.01 Gm. of atropine sulphate contained in a test-tube and heated until white vapors arise, add 1.5 Cc. of concentrated sulphuric acid and continue the heating until the mass turns brown, and then *cautiously* add 2 Cc. of water. An agreeable, peculiarly aromatic odor will be given off, which on the further addition of a small crystal of potassium permanganate is changed to that of oil of bitter almond. An aqueous solution of atropine sulphate, 1 part in 60 parts of water, yields no precipitate on the addition of solution of ammonium hydroxide, but is precipitated on the addition of solution of potassium or sodium hydroxide.—P. G. A saturated aqueous solution of the salt yields, upon addition of sodium carbonate solution, a white precipitate having the properties of atropine, which see (Br.).

Action and Uses.—A solution of atropine instilled into the eye produces mydriasis by stimulating the radiating muscular fibers and the sympathetic nerve-fibers of the iris, and by paralyzing the peripheral ends of the motor oculi nerve. The action of the ciliary muscle is also suspended and paralysis of accommodation results, during which time physiological rest is maintained. Atropine also increases intraocular tension, but its application does not cause irritation or inflammation. The drug causes dilatation of the pupil in about 15 minutes, and complete paralysis of accommodation in about 2 hours. If 1 drop of a solution containing 4 grains (0.25 Gm.) in 1 ounce (30 Cc.) of water is employed 3 times in 1 day, paralysis of accommodation lasts about 1 week, but if its application is continued until the third or fourth day, the normal function of the

ciliary muscle is not restored before the twelfth or fourteenth day. Because of this fact it lends itself to the control of many congestive conditions resulting from pre-existing eyestrain. It is invaluable in the treatment of retinochoroidal disturbances and in iridochoroiditis. Because of its prolonged action, atropine is the best drug to employ in choroiditis associated with or resulting from ametropia. Synechia arising from iritis or other inflammatory condition of the eye, and possible prolapse of the iris after corneal perforation, may be prevented by its timely application. Its employment permits of a thorough inspection of the eye-ground and the transparent media of the eye, facilitates cataract operations, and makes possible the accurate determination of refractive errors. (For other action and use of atropine, see BELLADONNA.)

The ordinary dose of atropine, internally or hypodermically, is from $\frac{1}{150}$ to $\frac{1}{60}$ of a grain (0.0005–0.001 Gm.), but as much as $\frac{1}{20}$ of a grain (0.003 Gm.) may be employed when the condition justifies it.

OTHER SALTS OF ATROPINE.

Atropinæ Boras. *Atropine borate*, E.; *Atropinborat*, G.—Contains 33.3 per cent. atropine. It is not a definite chemical compound, but simply a mixture prepared by dissolving 1 part of atropine and 2 parts of boric acid in alcohol, evaporating to dryness, and pulverizing the mixture. A white powder soluble in water.

Atropinæ Iodas. *Atropine iodate*, E.; *Atropinjodat, Jodsaures Atropin*, G. $C_{17}H_{23}NO_3.HIO_3$. Molecular weight, 461.58.—Contains about 62 per cent. of atropine. It is prepared by neutralizing atropine, dissolved in alcohol, with its molecular proportion of iodic acid, and then concentrating the solution until it crystallizes on cooling. Colorless needle-shaped crystals soluble in water and alcohol. Generally used in solutions containing 0.5–15 per cent.

Atropinæ Salicylas. *Atropine salicylate*, E.; *Atropinsalicylat, Salicylsaures Atropin*, G. $C_{17}H_{23}NO_3.C_7H_6O_3$. Molecular weight, 424.05.—Contains 67.7 per cent. of atropine. Prepared by dissolving 2.89 parts of atropine in about 10 Cc. of alcohol and neutralizing with the requisite amount (1.38 parts) of salicylic acid, evaporating off the alcohol, and then drying the mass in a drying oven. A white crystalline powder sparingly soluble in water.

Atropinæ Santoninas. *Atropine santoninate*, E.; *Santoninsaures Atropin*, G.—10 parts of atropine and 8.5 parts of santonin are dissolved in dilute alcohol and the solution then evaporated to dryness. A colorless to white crystalline powder soluble in water.

Atropinæ Stearas. *Atropin stearate*, E.; *Atropinstearinat, Stearinsaures Atropin*, G. $C_{17}H_{23}NO_3.C_{18}H_{36}O_2$. Molecular weight, 569.18.—Contains 50.4 per cent. of atropine. Prepared by neutralizing 2.84 parts of stearic acid with a hot 2 per cent. solution of sodium hydroxide, and adding it to 2.89 parts of atropine dissolved in 50 parts of water; the resulting precipitate is collected, washed with water, and recrystallized from alcohol. Thin white glistening needles, fatty to the touch, soluble in oils, and melting at 120° C. (248° F.).

Atropinæ Valerianas. *Atropine valerianate*, E.; *Atropinvalerianat, Baldriansaures Atropin*, G. $C_{17}H_{23}NO_3.C_5H_{10}O_2 + H_2O$. Molecular weight, 406.23.—Contains about 70 per cent. of atropine. 29 parts of dry atropine and 10 parts of anhydrous valerianic acid are intimately mixed and ground in a mortar and then dissolved in 16 parts of absolute alcohol and poured into 110 parts of ether, and the valerianate crystallized at about 0° C. (32° F.). Anhydrous materials must be used throughout, or the valerianate will be recovered simply as a thick, syrupy mass. Atropine valerianate occurs as colorless or white crystalline masses, hygroscopic, softening at about 20° C. (68° F.), melt at 42° C. (107.6° F.), and at higher temperatures rapidly lose valerianic acid. The crystals have the odor of valerianic acid, are soluble in all proportions of water and alcohol, and sparingly soluble in anhydrous ether.

AURANTII AMARI CORTEX, *U. S.*—Bitter-orange Peel.

Cortex Aurantiorum, Cortex Pomorum Aurantii; Aurantii cortex, B. P.; *Seville-orange peel, Wild-orange peel*, E.; *Pomeranzenschale*, G. (*Cortex Fructus Aurantii*, P. G.); *Pericarpium Aurantii, Malicorium Aurantii*, Russ.; *Flavedo Aurantiorum*, Austr.; *Écorce* (*Zeste*) *d' Orange Amere* (*de Curaçao*), Fr.; *Cortex Aurantiorum Curassaviencis*, Belg.; *Corteza de Naranja Agria*, Span.; *Casca de Curaçao, Casca de Laranja Azeda*, Port.; *Corteccia di Arancio Amaro*, It.

The dried rind of the fruit of *Citrus amara* (L.) Lyons (*C. Aurantium amara* L.; *C. Aurantium Bigaradia* (Loisel) Hook. f.; *C. Bigaradia* Loisel; *C. vulgaris* Risso.—Fam. *Rutaceæ*).

Bitter-orange peel is official in all pharmacopœias, some of which require it from the green, others from the ripe fruit. The U. S. description, though not the definition, determines the former. It is here impracticable to employ the fresh rind, as is done in

the case of sweet-orange peel, since the bitter orange is not an article of commerce with us.

Dried sweet-orange peel is frequently used as an adulterant or substitute.

Origin.—The bitter-orange tree closely resembles the sweet, though somewhat smaller. The fruit is large, of irregular, puffy form and a deep-orange color, and with a much rougher, thicker, and more spongy rind. The flesh is both sour and bitter and quite inedible, although much used for preserves. It is often known as "wild orange," but is largely cultivated.

Description.—In narrow, thin bands, or in quarters; epidermis of a dark brownish-green color, glandular, and with more or less of the spongy white inner layer adhering to it; it has a fragrant odor and an aromatic, bitter taste.—U. S.

A special variety, cultivated in Curaçao, and so named, much thinner than the ordinary, is in the market.

Constituents.—For the volatile constituents, see Oleum Aurantii Corticis. The bitter constituents are: (1) *Naringin* (de Vrij's hesperidin or aurantiin ($C_{23}H_{26}O_{12}$?), a very bitter yellowish crystalline glucoside, soluble in alcohol, acetic acid, and 300 parts of water, and insoluble in ether, chloroform, and volatile oils. Heated with dilute acids, it splits into naragenin ($C_{15}H_{12}O_5$) and isodulcit. (2) *Aurantiamarin*, 1.5 to 2.5 per cent., yields an amorphous glucoside, readily soluble in water, to which the bitterness of the peel is chiefly due. (3) *Isohesperidin* ($C_{22}H_{26}O_{12}$), 0.4 to 3 per cent., a slightly bitter glucoside. (4) *Aurantiamaric acid* ($C_{10}H_{12}O_4$), 0.1 per cent., very bitter, green, uncrystallizable and resinous, and soluble in hot water. Other principles are *hesperic acid*, 0.05 per cent., and *hesperidin* ($C_{22}H_{26}O_{12}$), a tasteless glucoside in minute white hygroscopic needles, soluble in acetic acid, alcohol, and 500 parts of hot water, and insoluble in ether, chloroform, or acetone. It turns red-brown with ferric chloride, and with dilute acids yields glucose, isodulcit, and *hesperetin* ($C_{10}H_{16}O_4$), which crystallizes in plates with sweetish taste. Orange-peel contains also gum, albumin, some fixed oil, resin, volatile oil, and a principle resembling tannin in its behavior to iron salts.

Pharmaceutical Preparations.—Fluidextract of Bitter-orange Peel, U. S. P.; Tincture of Bitter-orange Peel, U. S. P.

Action and Uses.—Bitter-orange peel is employed as an aromatic carminative and stomachic. It is rarely used alone, but is generally combined with purgatives to diminish their griping effect, or exhibited in conjunction with the simple bitters to assist in disguising their disagreeable taste. In small amounts it has been employed to relieve nausea and colic, but if administered in overdose may cause both of these conditions. If large quantities are ingested, especially by children, convulsions may occur.

The dose of the fluidextract is from 30 minims to 1 fluidrachm (2–4 Cc.); of the tincture, from 1 to 2 fluidrachms (4–8 Cc.).

Allied Products.—Orange Berries (*Petits grains*, Fr.; *Orangettes, Unreife Pomeranzen*, G.; *Aurantia Immatura, Fructus* [or *Baccæ*] *Aurantii Immaturi*) are the dried unripe fruits. They are globular or ovate-globose, 5 to 15 Mm. ($\frac{1}{5}$ to $\frac{3}{5}$ In.) in diameter, with a basal circular scar surrounded by 8 to 12 smaller depressions, and slight style-remains at the apex, greenish- to brownish-black, densely rugose, 10- to 12-celled, with a central placenta and 2 rows of rudimentary seeds in each cell. Odor, taste, constituents, and uses are similar to those of bitter-orange peel.

Orange Flowers (*Aurantii Flores; Flore naphæ.—Fleurs d'oranger*, Fr.; *Orangenblüthen, Pomeranzenblüthen*, G.; *Azahar*, Sp.; *Aranelo amaro*, F. It.) are the partly expanded flowers of either the sweet or bitter orange, though the official oil (see Oleum Aurantii Florum) is from the latter. They are marketed, pressed into jars with half their weight of common salt.

Fig. 53.

Orange flower (½ Nat.).

Description (Fig. 53).—Calyx small, 5-toothed; corolla white (brownish when dried), of 5 oblong, obtuse, fleshy, glandular-punctate petals about 12 Mm. ($\frac{1}{2}$ In.) long; stamens about 20, basally united into 3 or more bundles; ovary globular, on a small fleshy disk, the style cylindrical and stigma globular; highly odorous, especially the bitter species, taste aromatic and bitterish. Lemon flowers are purplish externally and the odor is distinct.

Orange flowers contain, besides the oil, gum, a little bitter extractive probably similar to that of the peel, and acetic acid.

AURANTII DULCIS CORTEX, *U. S.*—Sweet-orange Peel.

Ecorce (Zeste) d' Orange, Fr.; *Corteza de Naranja Dulce*, Sp.; *Casca de Laranja Doce*, Port.

The undried outer rind of the ripe fruit of *Citrus Aurantium* L. (*Aurantium Olyssiponense* Tourne; *Citrus dulcis* Pers.—Fam. *Rutaceæ*).

Fresh orange peel requires no description. It is only slightly bitter. The dry peel, which is very largely used, contrary to official requirement, closely resembles bitter-orange peel, except in its taste and its orange-yellow color.

The active constituent is an oil almost identical with that of the bitter peel. Other constituents are also similar, but the bitter principle is present in exceedingly small amount.

Pharmaceutical Preparations.—Syrup of Orange, U. S. P.; Tincture of Sweet-orange Peel, U. S. P.

Action and Uses.—Sweet-orange peel is used principally as an aromatic, but may be employed for the same purposes as bitter-orange peel (see Aurantii Amari Cortex). Its preparations are commonly used as vehicles for potent remedies.

The dose of the tincture is from 1 to 4 fluidrachms (4–16 Cc.). The syrup may be given *ad libitum*.

AURI ET SODII CHLORIDUM, *U. S.*—Gold and Sodium Chloride.

Chloraurate de sodium, Chlorure d'or et de sodium, Fr.; *Natriumgoldchlorid*, G.; *Cloruro di oro e di sodio*, F. It., Sp.

A mixture composed of equal parts, by weight, of dry gold chloride and dry sodium chloride, containing not less than 30 per cent. of metallic gold. It should be kept in well-stoppered, amber-colored vials.—U. S.

The official preparation is not the true double salt of the same name, but simply a mixture of the two chlorides. The double chloride of gold and sodium, known also as sodium chloraurate, contains about 76 per cent. of pure auric chloride, whereas the official compound contains but 50 per cent. The exact composition of commercial gold and sodium chloride depends upon the mode of preparation; a simple mechanical mixture made by triturating sodium and gold chlorides together in equal proportions would be in conformity with the official definition.

A solution of metallic gold in a mixture of nitric and hydrochloric acids contains chlorauric acid, according to the equation: $Au_2 + 2HNO_3 + 8HCl = 2HAuCl_4$ or $2(AuCl_3 + HCl) + 2NO + 4H_2O$; and by adding sodium chloride to such a solution the double salt, sodium chloroaurate, is obtained upon evaporation; thus, $HAuCl_4 + NaCl = NaAuCl_4$ or $(AuCl_3 + NaCl) + HCl$. For the formation of this compound 5.187 parts of auric chloride require 1 part of sodium chloride.

Properties.—This preparation is an orange-yellow powder slightly deliquescent in damp air, odorless, and having a saline and metallic taste. The compound is very soluble in water; at least one-half of it should be dissolved by cold alcohol. When exposed to a red heat, it is decomposed and metallic gold is separated. A fragment of the compound imparts an intense, persistent yellow color to a non-luminous flame. Its aqueous solution has a slightly acid reaction, and yields with test-solution of silver nitrate a white precipitate insoluble in nitric acid.—U. S.

The French Codex orders the crystallized double salt, $NaCl.AuCl_3,2H_2O$ (molecular weight, 395.06), to be prepared by dissolving the auric chloride prepared from 10 parts of gold in sufficient distilled water, adding 3 parts of sodium chloride, and evaporating to crystallization. It forms orange-colored rhombic prisms or plates which are soluble in water and alcohol, not deliquescent, fusible, and at a red heat are gradually decomposed, 49.4 per cent. of metallic gold being separated. It is known in France as *sel de Chrestien* and *sel de Figuier*.

Tests.—On bringing a glass rod which has been dipped into ammonia water close to a portion of the compound, no white fumes should appear (absence of free acid). If 0.5 Gm. of gold and sodium chloride be dissolved, in a porcelain capsule, in 25 Cc. of water, the solution made alkaline by the addition of 5 Cc. of potassium hydroxide test-solution, and, after the addition of 5 Cc. of hydrogen dioxide solution, heated for 1 hour on a boiling water-bath, a precipitate of metallic gold will be obtained, which,

when washed, dried, and ignited, should weigh not less than 0.15 Gm. (corresponding to at least 30 per cent. of metallic gold). The filtrate from the precipitated gold should not be affected by hydrogen sulphide test-solution, nor, after being supersaturated with ammonia-water, by ammonium sulphide test-solution (absence of metallic impurities).—U. S.

Action and Uses.—Gold when used in medicine is almost always employed as chloride of gold and sodium. Gold and sodium chloride is said to possess alterative properties, but its action upon the system is unknown. Formerly it was employed in the treatment of hysteria, hypochondriasis, dysmenorrhœa, laryngismus stridulus, asthma, ovarian neuralgia, and chronic metritis. It was also thought to be beneficial in the treatment of tabes dorsalis, cirrhosis of the liver, and chronic interstitial nephritis, on the ground that it materially decreases the amount of connective tissue in the parts, but clinical experience has not justified this claim. This salt has been recommended as a valuable adjunct to mercury in the treatment of the later syphilitic manifestations, but in these conditions its value has probably been overestimated. It is said to be the preparation employed by quacks in the treatment of the alcohol habit, but it has no specific action upon the condition, and the tonics and stimulants given with it, combined with a good regimen, are probably of much more value. Its employment in pulmonary tuberculosis is also without benefit. Gold and sodium chloride acts as a stimulant to the nervous system, and has been used with asserted success in sexual impotence.

Gold and sodium chloride is given in the dose of $\frac{1}{20}$ grain (0.003 Gm.), in pill-form, 3 times daily; it has been mixed with inert powder and applied by friction to the sides of the tongue.

AURUM.—Gold.

Or, Fr.; *Gold*, G.; *Oro*, F. It., Sp.

Symbol, Au. Atomicity univalent and trivalent. Atomic weight, 195.7.

Origin and Properties.—This well-known metal is chiefly found in the metallic state, always associated with other metals and frequently in various native sulphides. It is the most precious of all metals, and the only one with a yellow color. It is the most ductile of all metals, softer than silver, fuses at about 1070° C. (1958° F.), has the density 19.3 and a metallic luster, but when powdered, a brown color, acquiring luster by pressure. It is not altered by exposure to air and water, and does not dissolve in acids, but is soluble in liquids containing or generating chlorine. Gold is extracted from its ores chiefly by two methods, known as the *cyanide* and the *chlorination* processes. In the former, the finely divided gold in the powdered ore is dissolved out by a solution of potassium cyanide, from which it is precipitated by zinc or deposited electrolytically on lead plates. Since the introduction of this method in the Transvaal, the output of gold has been increased by about half. In the chlorination process, the roasted ore is treated with chlorine water, which converts gold into its chloride, which is precipitated from the solution by reducing agents, such as ferrous sulphate, or by passing through long columns of wood-charcoal, which precipitates the gold upon itself. Besides these two processes, gold is also extracted by the *amalgamation* process, which consists in dissolving out the gold by mercury to form an amalgam, from which the mercury is finally distilled, leaving the gold. The world's production of gold and silver averaged in tons of 2200 pounds:

	Gold.	Silver.
1881–1890	160	3080
1891–1895	235	4730
1896–1898	400	5000

On account of its softness, pure gold is unsuitable for coins, apparatus, etc., and is therefore alloyed with copper or silver, or both. The purity of gold is designated by the word "carat." Pure gold is 24 carat. 14 carat means 14 parts of pure gold and 10 parts of other metal. The purity is also expressed in percentage or milligrams of pure gold in 1 Gm. of alloy. Thus, the purity of 14-carat gold is 58.33 per cent., or 0.5833.

AURUM FOLIATUM, *gold-leaf*, is transparent, with blue or green color; it should not be attacked by nitric acid nor become tarnished by ammonia.

AURI PULVIS, *powdered gold*, may be prepared by triturating gold-leaf with crystals of milk-sugar, potassium sulphate, or other hard soluble substance, until the metallic

lustre has completely disappeared, when the compound is washed out with water (obsolete). A solution of gold chloride yields the metal in a finely divided condition when added to solution of ferrous sulphate, oxalic acid, or other oxidizable compound. Aurum colloidale, colloidal or soluble gold, like silver, may be obtained by reducing a weakly alkaline solution of gold with formaldehyde, and purifying it from other substances by dialysis.

UNOFFICIAL GOLD SALTS.

Auri et Ammonii Chloridum.—*Gold-ammonium chloride.*—Equal parts of auric chloride and ammonium chloride are dissolved in water, acidulated with hydrochloric acid, and the solution evaporated to dryness (Dorvault). It resembles the preceding.

Auri Bromidum.—*Gold bromide.* $AuBr_3$.—Formed by bringing together under water finely divided gold and bromine in equivalent quantities and evaporating to dryness. It is dark-brown, soluble in water, alcohol, and ether.

Auri Chloridum.—*Gold chloride or Auric chloride.* $AuCl_3$.—On dissolving pure gold in nitromuriatic acid and crystallizing, yellow *hydrogen-gold chloride*, $AuHCl_4.4H_2O$, is obtained, which in a dry atmosphere loses $1H_2O$ (Julius Thomsen, 1878, 1883). But on evaporating the solution to dryness, dissolving in water, filtering from aurous chloride, AuCl, and again evaporating, auric chloride is obtained as a dark-red or red-brown salt. It is decomposed above 150° C. (302° F.), dissolves readily in water, and is also soluble in alcohol, ether, and volatile oils, which solutions are gradually reduced. Its solution yields with stannous chloride a dark-brown or purple precipitate known as *purple of Cassius*, which consists of a mixture of colloidal gold and colloidal stannic acid in varying amounts, and finds application in porcelain- and glass-painting.

Auri Cyanidum.—*Gold cyanide.*—Prepared best, according to Figuier (1874), by dissolving pure auric chloride in water, and adding a solution of an equivalent weight of pure potassium cyanide, when a lemon-yellow precipitate will be obtained; a larger quantity of the latter solution would change the color to brownish- or orange-yellow. It is inodorous and tasteless, and contains 75 per cent. of gold. With an excess of potassium cyanide, used in a concentrated hot solution, *auro-potassium cyanide*, containing 55 per cent. of gold, is obtained in colorless tabular crystals, which on exposure become white from loss of water of crystallization.

Auri Iodidum.—*Gold iodide.* AuI_3.—Obtained by precipitating a solution of auric chloride with potassium iodide, avoiding an excess of the latter, washing with water, and drying carefully. It is a dark-green powder, which is soluble in solution of potassium iodide, and on exposure loses iodine, being first converted into yellow *aurous iodide*, AuI, and finally into metallic gold.

Auri Oxidum.—*Auric acid, Gold hydroxide.* $Au(OH)_3$.—Pelletier directs the boiling of a solution of auric chloride with an excess of magnesia or zinc oxide, collecting the precipitate upon a filter, and washing it first with dilute nitric acid (which must be free from chlorine), and afterward with water. Frémy (1850) adds to auric chloride sufficient solution of potassium hydroxide until the precipitate is redissolved; the solution is boiled for 15 minutes, or until its dark-brown color has changed to light-yellow, when it is acidulated with sulphuric acid and the precipitate washed and dried; it retains a trace of potassium. Gold hydroxide is a blackish-brown powder which is readily soluble in hydrochloric and hydrobromic acids, and when heated to 245° C. (473° F.) or boiled with alcohol yields metallic gold. It dissolves in alkalies to form metaurates; for example, $KAuO_2$, a salt of metauric acid, $HAuO_2$.

Action and Uses.—All of the salts of gold are irritant poisons, and when ingested in poisonous dose cause gastro-intestinal inflammation with violent pain, vomiting, and purging. The chloride especially acts in this way, as it possesses the properties of a caustic, resembling in its action silver nitrate. Gold chloride has been locally applied to cancerous and other chronic ulcers, but the cost of the drug prevents its general use in medicine. The oxide is said to be an alterative, and may be given internally in scrofulous conditions in the dose of $\frac{1}{10}$ grain (0.006 Gm.), or gradually increasing doses may be rubbed into the gums or the sides of the tongue with friction. The cyanide has been found useful in syphilis and scrofulosis but is rarely employed at the present time. It may be given internally in the dose of $\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003–0.006 Gm.), or diluted with some inert powder and rubbed into the sides of the tongue. Gold ammonium chloride is said to be of use in the treatment of amenorrhœa, dysmenorrhœa, and ovarian neuralgia. The dose is $\frac{1}{10}$ grain (0.006 Gm.). The iodide has been recommended in syphilitic affections in doses of $\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003–0.006 Gm.). Gold bromide depresses the motor areas of the cortex and has been successfully employed in the treatment of epilepsy. Its action is said to be more prolonged than that of any other bromide, and its continued use does not cause bromism probably because in the small doses in which it is used it carries very little bromine into the body. It has also been recommended in chorea, hysteria, migraine, and exophthalmic goitre. The dose commonly given is from $\frac{1}{5}$ to $\frac{1}{2}$ grain (0.010–0.03 Gm.), 3 times daily.

AZEDARACH.—China Tree; Pride of China.

Indian or African lilac or Lilac-tree, Bead-tree, False sycamore, Hoop-tree, E.; *Zedrachrinde,* G.; *Écorce d'azedarach, Écorce de margousier,* Fr.; *Flor de Paris,* Sp.

The dried bark of the root of *Melia Azedarach* L. (Fam. *Meliaceæ*).

Origin.—From a handsome, rapidly growing tree, resembling a very large apple tree, native of southeastern Asia, extensively cultivated in tropical and warm-temperate regions, and naturalized along our Gulf coast. It blooms profusely, the handsome and fragrant panicles resembling those of the common lilac, and bears spherical fruits about 12.7 Mm. ($\frac{1}{2}$ In.) in diameter, the solitary large seed loosely enclosed in a fleshy pericarp. Besides their medicinal use, these fruits have been fermented for the production of alcohol. They are very bitter, this taste pertaining also to the fixed oil expressed from them, and are employed as an anthelmintic, antiperiodic, and locally as an antirheumatic. A poultice of the flowers is reported as being parasiticide and sedative.

Fig. 54.

Azedarach root-bark, with outer bark present (Nat.).

Description.—In quills, strips, or curved pieces of irregular size, externally blackish-brown and glossy if young, this layer present in the older bark only in patches upon the reddish- or rusty-brown lower layer, or completely giving place to the latter, which varies greatly in relative thickness; inner bark white, containing few scattered pale-yellow bast-fibers, and tangentially striate. Inner surface pale-brown or whitish, uneven, and longitudinally striate; fracture short and smooth in the outer, slightly fibrous in the inner layer; taste slight in the outer, sweetish, then bitter and nauseous in the inner layer. It is the inner bark only which should be employed.

Composition.—Tannin exists in the outer, but not in the inner bark. There is a little sugar. The bitter and medicinally active constituent is believed to be a yellowish-white resinous body, freely soluble in alcohol, ether, and chloroform, somewhat soluble in hot, but scarcely in cold water, but it is more likely some body associated with, and not yet isolated from this resinous substance.

Action and Uses.—The bark of *M. Azedarach,* in the form of a decoction, is employed as an anthelmintic for the removal of the round worm. The decoction is made by boiling 2 ounces (60 Gm.) of the drug in a quart (960 Cc.) of water, until only 1 pint (480 Cc.) remains. This is given in the dose of $\frac{1}{2}$ to 1 fluidounce (16–30 Cc.) every 2 hours until the bowels move.

In overdose the bark produces symptoms similar to those caused by spigelia and belladonna (see Belladonna-poisoning).

The fruit does not appear to possess the toxic properties characteristic of the bark, as they are frequently eaten by children and birds without ill effect.

The entire plant of *M. Azedarach* is employed in medicine as a tonic and antiperiodic, and the bark and leaves are official in the pharmacopœia of India. An oil expressed from the seeds has been recommended as an embrocation in chronic rheumatism.

M. AZADIRACHTA L., the *Nim* or *Nimb*, also called *Indian lilac*, is a similar tree of India, its medicinal use much greater there than is that of the preceding. All parts of the tree are employed, as well as an oil expressed from the seeds and a gum which exudes from the bark. Like the preceding, it is anthelmintic throughout, the bark being most largely used. It is externally rusty-gray and roughly fissured, yellowish on the inner surface, and has a fracture similar to that above described. The inner bark is bitter, the outer astringent. The bitter principle of the inner bark appears to be a neutral resin, or is perhaps contained in this resin.

The oil expressed from the seed is in commerce under the name of *Nim*, *Neem*, or *Margosa oil*, and is of a yellowish color and a strong, garlicky odor. It is very bitter. Thoroughly washed with alcohol, it loses to a great extent its odor and taste. (For complete description, see *Phar'g'a Ind.*, 1, 327.)

Decoctum Azadirachtæ, as a tonic, is administered in the dose of 1 fluidounce (30 Cc.), 3 times daily; as an antiperiodic, it is given every 2 hours before the expected paroxysm.

Tinctura Azadirachtæ is given in the dose of 1 to 2 fluidrachms (4–8 Cc.).

M. dubia Cav., the *Dinkarling* or *Nimbara*, is another Indian species, which is apparently very similar in its properties.

B.

BALSAMUM PERUVIANUM, *U. S., Br., P. G.*—Balsam of Peru.

Balsamum peruvianum nigrum, Balsamum indicum. Peru Balsam, Indischer Balsam, G.; *Baume du Pérou, Baume des Indes, Baume de Sansonate,* Fr.; *Balsamo negro, Balsamo de San Salvador,* Sp.; *Balsamo peruviano,* F. It.

A balsam obtained from *Toluifera Pereiræ* (Royle) Baill. (*Myrospermum P.* Royle; *Myroxylon P.* Klotzsch.—Fam. *Leguminosæ*).

Official in all pharmacopœias, some of which use one or another of the synonyms, instead of the generic name, published by Linné.

Origin.—From a handsome tree, yielding a precious mahogany-like wood. It is similar to, but somewhat smaller than, that yielding Tolu balsam. It grows in and near San Salvador, the country of exportation, chiefly at an altitude of from 1000 to 2000 feet. The balsam derived its misleading name from a supposition that it came form the *T. peruifera* (L. f.) Baill. (*Myroxylon P.* L. f.; *Myrospermum P.* DC.), of Peru, but that is now known to be quite distinct and inferior. The error is said to be due to its having been sent first to Callao and thence exported. The natives are said to recognize two varieties of the tree, distinguished chiefly by their bark-thickness, but this distinction does not extend to the balsam. Besides the commercial balsam, a small amount of a somewhat different substance, having the odor of vanilla, is collected from the fruit-cavity surrounding the seed. This, all consumed at home, is more highly esteemed than the commercial. A fragrant oil is yielded by the leaves. The tree is occasionally cultivated.

Collection.—When the tree is about 10 years old and the trunk about 0.34 M. (1 foot) in diameter, tapping commences. No balsam is found in the trunk or its bark except as the result of injury, though a non-aromatic gum-resin sometimes exudes. It is said that so long as an open wound exists in the bark a slight flow of balsam will continue. For the production of the balsam for collection, according to P. Preuss, the bark, down to the inner layer, is torn off in strips, and rags are bound upon the denuded surface to soak up the exudation, which appears in about a week, and is known as *tagauzonte*. The saturated cloths are removed and the bare surface is heated for about 5 minutes by a burning torch. The balsam is boiled out of the rags in water and collected from the bottom, where it sinks. About 8 days later a new flow, called *Balsam de trapo*, meaning *rag balsam*, commences, and is soaked up as before, and this process is continued so long as the flow lasts. The exposed parts are then deeply cut and scraped, to cause the occurrence of a third supply, called *Balsamo de contrapique*, meaning *balsam of the repeated wounding*. Sometimes an additional flow can afterward be caused by a second heating. If the process is carefully conducted, the lower wounds will heal while fresh ones are being worked above. After this, the loose bark and wood are ground up and extracted, and the extract added to the other collected portions. Some commercial balsam is wholly the product of bark-extraction. The annual yield is 3 to 5 pounds per tree, mostly between December and April, although some is obtained during the whole of the intervening period. There is a process of purification to remove foreign bodies, and then the balsam is packed in canisters with screw tops, of about 60 pounds capacity. Dieterich secured some perfectly pure balsam, specially collected for him, and found it much superior in appearance and odor to any sample of the commercial article. It yielded 77 per cent. of aromatic substances and only 13 per cent. of resins; whereas the commercial article, of the best quality, never yields more than 65 to 75 per cent. of aromatic substances. This would seem to indicate that adulteration is very generally resorted to. The chief adulterant, introduced by the native collectors, is water. The importations to the United States in 1899 amounted to about 4500 pounds. The greatest amount imported in one year was something over 10,000 pounds, in 1891.

Properties.—Balsam of Peru is a viscid liquid of a dark-brown color; free from stringiness or stickiness; transparent and reddish brown in thin layers; of an agreeable vanilla-like odor and a bitter, acrid taste, with a persistent after-taste. When swallowed,

it leaves a burning sensation in the throat. It does not harden on exposure to the air. It has a specific gravity of 1.130 to 1.140 at 25° C. (77° F.) (U. S.), or 1.137 to 1.150 (Br.), 1.140 to 1.150 (P. G.) at 15° C. (59° F.). Completely soluble in absolute alcohol, chloroform, and glacial acetic acid, only partially soluble in ether and petroleum benzin, soluble in 5 parts of alcohol, with not more than a slight opalescence (U. S.). Soluble in an equal volume of 90 per cent. alcohol, but on further addition of 2 more volumes of the alcohol, the mixture becomes turbid (Br.). Water, when agitated with the balsam, shows an acid reaction to blue litmus-paper.

Adulterants.—Balsam of Peru is frequently adulterated with alcohol, fixed oils, copaiba, Gurjun balsam, Canada turpentine, rosin, storax, benzoin, etc. If 10 drops of the balsam be triturated with 20 drops of sulphuric acid, a tough, homogeneous, brownish-red mixture should result, which, when washed with cold water, should develop a violet color upon its surface, and when drained be converted into a resinous mass which is brittle when cold (absence of fixed oils and oleoresins).—U. S., P. G. This resin should be perfectly soluble in ether (absence of benzoin), and in alcohol or acetone (absence of storax). "If 1 Gm. of the balsam be shaken with 5 Cc. of petroleum benzin, and the mixture warmed on a water-bath for 10 minutes, and a sufficient quantity of the solvent added to replace loss by evaporation, then if 2 Cc. of the benzin solution be evaporated, and treated with a drop of nitric acid (specific gravity 1.42), a permanent green or bluish-green color should not be produced (absence of rosin). The remaining 3 Cc. of the benzin solution, when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000), should not be colored green or bluish green (absence of rosin, turpentine, storax, fatty oils, etc.). On mixing the balsam with half its volume of calcium hydroxide and heating for ½ hour on a water-bath, a solid mass should not be formed (absence of rosin, storax, or copaiba). If 1 Gm. of the balsam be dissolved in 100 Cc. of alcohol and 1 Cc. of phenolphthalein test-solution be added, not more than 2 Cc. of half-normal alcoholic potassium hydroxide solution should be required to produce a pink color (limit of acid resins). Mix 3 Gm. of the balsam with 30 Cc. of sodium hydroxide test-solution and shake the mixture for a few minutes with 60 Gm. of ether. Transfer 51.1 Gm. of the ether-solution to a flask and evaporate to dryness. The residue, when dried to constant weight by a gentle heat, should weigh not less than 1.4 Gm. (presence of at least 56 per cent. of cinnamein). If this residue be dissolved in 25 Cc. of alcohol, then mixed with 25 Cc. of half-normal alcoholic potassium hydroxide solution, and heated carefully during ½ hour on a water-bath, it should require not more than 13.2 Cc. of half-normal hydrochloric acid to exactly neutralize the liquid, 1 Cc. of phenolphthalein test-solution being used as indicator."—U. S. "Balsam of Peru should not diminish in volume when shaken with an equal bulk of water (absence of ethyl alcohol). About 40 per cent. of resin should separate when 1 part of the balsam is treated with 3 parts of carbon disulphide, and the clear supernatant liquid should be of a pale-brown color with only a slight fluorescence (absence of Gurjun balsam)."—Br.

Constituents.—The balsam consists (Trog, 1894) of 60 to 64 per cent. of *benzyl benzoate* ($C_7H_5.C_7H_7.O_2$), a colorless oil boiling at 340° C. (644° F.), free vanillin, free cinnamic acid, a small portion of benzyl cinnamate, and 30 to 38 per cent. of resin composed of benzoic and cinnamic esters of peru-resinotannol. Kraut's *stilbene* ($C_{14}H_{12}$), in colorless and odorless pearly scales or prisms, has not been found by others. Trog found no styracin, free benzyl alcohol, free benzoic acid, or phenylpropyl cinnamate. Benzyl cinnamate ($C_9H_7.C_7H_7.O_2$), considered by Kraut the main constituent, is a colorless oily liquid, with faint agreeable odor and an aromatic sharp taste. It boils at 300° C. (572° F.), its specific gravity is 1.095, and by caustic alkalies it is decomposed into benzyl alcohol and cinnamic acid.

Cinnamein or Peru Balsam Oil, the oily liquid separated by agitation with sodium or potassium hydroxide, contains benzyl benzoate, benzyl cinnamate, benzyl alcohol (C_7H_7CH), and other aromatic compounds.

Action and Uses.—Balsam of Peru is not largely employed in internal medicine in this country. It is a stimulant to the mucous membranes, especially the bronchial, and may be employed in all chronic affections of the respiratory tract, such as chronic laryngitis, chronic bronchitis, asthma, and tuberculosis. Its employment in the latter affection is not attended with any benefit, however, other than moderation of the cough. Chronic rheumatism, diarrhœa and dysentery, leucorrhœa, and the later stages of gonorrhœa are said to be benefited by its use. Balsam of Peru is employed locally as an

application to indolent, suppurating ulcers, chronic nasal catarrh, and tubercular caries. Applied either pure or in the form of an ointment or liniment, it is said to be of value in the treatment of scabies, chronic eczema, and pruritus ani et vulvæ. It has also been used as a cure for fissured nipples and chilblains.

The internal dose is 5 to 15 grains (0.30–1 Gm.); or it may be employed by inhaling steam saturated with its volatile products.

Hofmann's balsam is given in the dose of 10 to 30 minims (0.60–2 Cc.).

Artificial Balsam of Peru.—Hager recommends the following substitute, for use in veterinary practice: Benzoin, 100 parts; pitch, 15; salicylic acid, 10; Gurjun balsam, 40; alcohol, 500. Dissolve, strain, and evaporate to the consistency of honey.

BALSAMUM TOLUTANUM, *U. S., Br., P. G.*—Balsam of Tolu.

Tolubalsam, G.; *Baume de Tolu, Baume de Carthagène*, Fr.; *Balsame de Tolu, B. Blanco*, Sp.; *Balsamo Tolutano*, F. It.; *Balsamum Americanum, B. Indicum Siccum.*

A balsam obtained from *Toluifera Balsamum* L. (*Myroxylon toluiferum* Kunth; *Myrospermum t.* A. Rich.—Fam. *Leguminosæ*).

Official in all pharmacopœias, some of which use one or other of the botanical synonyms instead of the original name published by Linné.

Origin.—From a handsome tall evergreen tree of the highlands of Venezuela and Colombia. The balsam occurs as a natural product only in the young tissues (leaves and bark of young twigs), where it exists in schizogenous cavities. This tissue is soon lost, by the falling of the leaves and by a process of bark-casting from the twigs, and does not reappear in the bark except as a result of injury, such as the incisions made in the trunk-bark to obtain it. It is therefore to be regarded as a probable method of defence by the plant against decay from wounding—that is, a process of natural antisepsis.

Collection.—Two sloping notches are cut through the bark, meeting at their lower ends in a sharp angle, below which the bark and wood are hollowed out a little to receive the calabash cup into which the balsam flows. Similar cuts are made as high up as a man can reach, or even higher by the aid of scaffolding. Often as many as 20 cups are found on one tree. Excessive collection is indicated by the appearance of very small and thin leaves. The balsam-gatherer collects the contents of the cups in flask-shaped bags made of raw-hide, a pair of them being slung over the back of a donkey. When filled, these bags are sent to the ports of exportation on the Magdalena River, where their contents are transferred to the cylindrical tins which arrive here, holding 10 or sometimes 25 pounds. During 1900, more than 50,000 pounds were imported into the United States. The largest importation, nearly 65,000 pounds, was in 1898.

Description.—Recently imported, Tolu balsam forms a semiliquid mass which gradually hardens, becoming quite brittle in the cold, but softening between the teeth and fusing readily at a somewhat elevated temperature. In thin layers, it is perfectly transparent and of a yellowish- or reddish-brown color. Viewed under the microscope, abundant crystals of cinnamic acid are observed. It has an acid reaction, an agreeable aromatic odor, suggesting that of vanilla, which becomes more apparent on warming it, and a mild aromatic taste. It is readily soluble in alcohol, chloroform, potassium hydroxide solution, and acetone; also in ether. Benzene and petroleum benzin scarcely act upon it, and carbon disulphide dissolves about 25 per cent.

Dissolved in the smallest quantity of potassium hydroxide solution, it acquires a clove-pink odor. By warming 1 Gm. with 5 Cc., then with 2 Cc. of carbon disulphide and evaporating to dryness, the residue should be distinctly crystalline, and should require not less than one-third of its weight of potassium hydroxide for saponification.

Constituents.—The balsam yields 7 per cent. of an acid, aromatic, oily liquid, chiefly benzyl benzoate, with a little benzyl cinnamate; 0.05 per cent. of vanillin; 0.2 to 1 per cent. of volatile oil, chiefly tolene ($C_{10}H_{16}$); 18 to 20 per cent. of free cinnamic acid, which may be obtained by distillation; and 75 to 80 per cent. of resin ($C_{18}H_{20}O_5$). This resin is a combination of tolu-resinotannol with cinnamic and a small proportion (about 1 or 1.5 per cent.) of benzoic acid. Part of this resin is soluble in carbon disulphide, on evaporating which, the residue should be crystalline and almost colorless, should be in the neighborhood of 25 per cent. of the balsam, and should have an acid number (*Braithwaite*) of not less than 300. The volatile oil rapidly hardens from oxidation on exposure to air. The balsam contains no styracin, is free from benzyl alcohol or phenyl-

propyl-cinnamate, and on dry distillation, besides its volatile constituents, it yields toluol (C_7H_8), styrol, and phenol.

Adulteration and Substitution.—These operations have been extensively practised. Common rosin, the resin of copaiba, storax, and various unknown resinous substances, have been used, either for adulteration or for entire substitution, so that careful attention to the description and tests is a necessity. In this connection, special emphasis is laid upon the abundance of crystals, as viewed under the microscope, upon the presence of about 20 per cent. of cinnamic acid, and upon the amount and character of the CS_2—soluble residue. The presence of turpentine, one of the commonest adulterants, is indicated by the blackish, instead of cherry-red, color imparted by treatment with concentrated sulphuric acid. Another practice sometimes resorted to is that of exhausting the Tolu by making the syrup from it, and then selling the resulting product as genuine. In such samples the percentage of cinnamic acid is found to be greatly reduced.

The U. S. P. prescribes the following tests: If 0.5 Gm. of the balsam be shaken with 25 Cc. of carbon disulphide and allowed to stand for 30 minutes, and then filtered, the residue obtained by evaporating the filtrate to dryness, when dissolved in glacial acetic acid, should not yield a green color on the addition of a few drops of sulphuric acid (absence of rosin). If 1 Gm. of balsam be shaken with 8 Cc. of petroleum benzin for 5 minutes, the supernatant liquid should not be colored green when shaken with an equal volume of copper acetate solution—1 in 1000—(absence of rosin and copaiba). If to 1 Gm. of balsam dissolved in 50 Cc. of alcohol, 1 Cc. of phenolphthalein test-solution be added, not less than 4 Cc. nor more than 6 Cc. of half-normal alcoholic potassium hydroxide solution should be required to produce a red color (limit of acidity); next add to this liquid more half-normal alcoholic potassium hydroxide solution until the total amount has reached exactly 20 Cc.; then heat the liquid in a water-bath for half an hour and allow it to cool. Not less than 13.2 Cc. nor more than 14.5 Cc. of half-normal sulphuric acid solution should be required to neutralize the excess of potassium hydroxide solution, phenolphthalein being used as indicator (limit of saponifiable substances).

Pharmaceutical Preparation.—Syrup of Tolu, U. S. P.

Action and Uses.—Balsam of tolu is a stimulating expectorant, and may be used in the treatment of subacute and chronic inflammations of the respiratory tract. Its agreeable odor renders it a valuable addition to many expectorant mixtures and lozenges, and the syrup prepared from it is frequently employed as a basis for cough mixtures. The inhalation of steam laden with the volatile portion of the drug is frequently beneficial in the treatment of acute laryngitis with aphonia and obstinate bronchitis.

It is best administered in the form of an emulsion prepared with acacia and sugar, in doses of 10 to 30 grains (0.60–2 Gm.).

Other Species.—The number of species in this genus has been variously estimated at from 2 to 6. They are poorly known, and it cannot at present be stated with certainty whether some of the published names are synonymous. The *Quino-quino* tree of Peru may be the same as the above or a distinct species, *T. punctatum* (Klotzsch) Baill.

BAPTISIA.—Wild Indigo.

American or Yellow indigo, Indigo broom or weed, Rattlebush, E.; *Pferdfliegenstrauch, Baptisie, Wilder Indigo,* G.; *Indigo Sauvage,* Fr.

The root of *Baptisia tinctoria* (L.) Br. (*Sophora t.* L.; *Podolyria t.* Mx.). The herbage has also been similarly used.

Origin.—This showy perennial smooth herb is abundant in dry sandy or gravelly soil, especially on the edges of forests or amid shrubbery, throughout eastern and central North America. It forms a dense, rounded mass, nearly 1 M. (2 or 3 Ft.) high and broad, of slender, erect, leafy branches and branchlets, covered with bright-yellow flowers. Leaf- and flower-habit are here illustrated (Fig. 57).

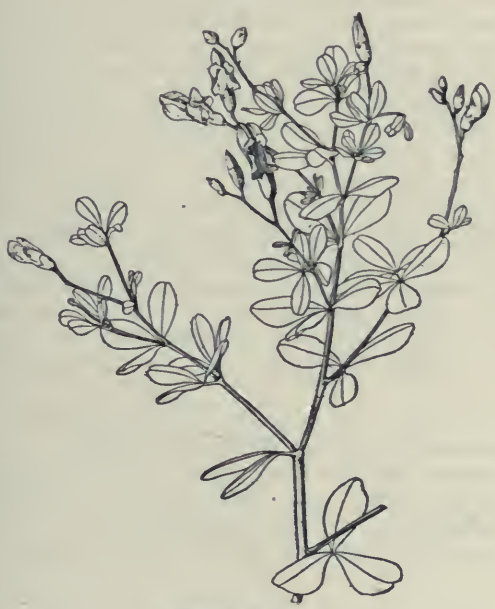
Description.—Crown, 5 to 7 Cm. (2 to 3 In.) thick, knotty, bearing several stem-scars; root terete, fleshy, quickly dividing into several cylindrical branches, often 60 Cm. (2 Ft.) or more in length and 1.2 Cm. (0.5 In.) or more thick, and sparsely beset with branching rootlets; externally dark-brown, with small warts arranged in transverse rows, or with a soft and friable corky layer; internally whitish, radially striate, thick and fleshy, covering a whitish, tough, porous wood with indistinct medullary rays; odor slight; taste of the bark bitterish, acrid, and nauseous, the wood nearly tasteless.

Constituents.—Besides resin and ordinary plant-constituents, Baptisia has been found to contain cytisine (*baptitoxine*) and one or two glucosides. *Baptisin* ($C_{26}H_{32}O_{14} + 9H_2O$, *Gorter*) is somewhat soluble in water and dilute alcohol, and melts at 240° C. (464° F.). It does not appear to be active. It yields *baptigenin*. *Baptin* occurs in needle-shaped crystals and is purgative.

Action and Uses.—Baptisia is said to be a violent emeto-cathartic, and an hepatic and intestinal stimulant. Moderate amounts increase the respiratory function and reflex activity, but poisonous doses produce death by respiratory paralysis. Internally, baptisia has been recommended in the treatment of typhus and scarlet fevers, and in epidemic dysentery. The drug has also been employed as a nervous stimulant and antipyretic in enteric fever, but its power in this condition has probably been overestimated. The decoction has been employed both internally and as a topical application in the treatment of aphthous stomatitis, chronic ulcers, and gangrene, but more potent remedies are commonly used in these conditions.

The tincture is given in the dose of from 1 to 5 minims (0.05–0.30 Cc.); the decoction, made by boiling 1 ounce (30 Gm.) of the drug with 1 pint (480 Cc.) of water, is usually given in doses of ½ fluidounce (15 Cc.) every 4 hours, and may be combined with tincture of opium to prevent vomiting. The dose of baptisin is from 2 to 5 grains (0.10–0.30 Gm.).

FIG. 55.



Baptisia (¾ Nat.).

B. alba R. Br., of the southern United States, is said to act and to be used similarly. Probably others of the 14 species, all of North America, have like properties.

BARIUM.—Barium.

Baryum, Fr., G.

Symbol, Ba. Atomicity bivalent. Molecular weight, 136.4.

Barium occurs in combination principally in two minerals, heavy spar, $BaSO_4$, and witherite, $BaCO_3$. It is also found to a small extent in some manganese ores and some silicates. An amalgam of barium was obtained by Berzelius and Pontin in 1808, and in the same year Davy isolated the metal by distilling the mercury from the amalgam. The latter is obtained by adding sodium amalgam to a hot saturated solution of barium chloride at 93° C. (199.4° F.), and kneading the barium amalgam formed in cold water to remove sodium.

Properties.—Barium is a lustrous, light-yellow metal of the specific gravity 3.6, and is rapidly oxidized on exposure to air. It acts energetically on water, liberating

hydrogen and forming barium hydroxide, $Ba(OH)_2$, also called *baryta*, which has strong alkaline properties similar to those of caustic soda, NaOH. Barium belongs to the group of elements known as *alkaline earth* metals, which consists of calcium, strontium, and barium. The name indicates the fact that the members of the group have properties which resemble those of the alkali metals as well as those of the earth metals. All soluble barium compounds are very poisonous. The proper antidote is a sulphate, for example, Glauber's or Epsom Salt, which forms the insoluble barium sulphate.

Action and Uses.—As barium chloride is the representative salt of barium, its uses will be considered here. When moderate doses of barium chloride are administered, the rapidity of the heart's action is decreased, its rhythm is steadied, a greater quantity of blood is forced out of the ventricle, and arterial tension is increased. The pulse beats more slowly and the pulse-wave is very materially prolonged. Barium chloride directly stimulates the heart muscle and the muscular coats of the arteries. It probably has no effect upon the vagus nerve or upon the vasomotor center, but the short period during which the heart's action is increased probably results from the stimulant action of the drug upon the accelerator nerves. Barium chloride is rapidly absorbed, and may be found in nearly all the tissues of the body, especially in the kidneys, liver, nerve-centers, and bones.

The drug is employed as a cardiac stimulant in all conditions resulting from failure of the heart muscle. It has been recommended in sclerotic nervous lesions, and is said to be of value, both when given internally and applied locally, in the treatment of varicose veins. It has been recommended and condemned by various members of the profession in the treatment of glandular tuberculosis, but the consensus of opinion at present is that it is of little value in this condition. Excessive amounts of barium chloride cause gastro-enteritis, with nausea, vomiting, pain, and serous purging. Collapse with its characteristic symptoms, followed by convulsions and death, results when the dose is sufficiently large. Death results from cardiac arrest due to the violent stimulating effects of the drug upon the heart muscle. Respiratory paresis occurs almost simultaneously. The treatment consists in the use of the stomach-pump or the employment of emetics and the administration of any of the soluble sulphates. Pain may be relieved by opium and demulcent drinks and appropriate stimulants may be used as indicated.

Barium chloride has been recommended as an alterative in the treatment of scrofulosis.

Barium chloride is usually employed in solution. One containing 5 grains (0.30 Gm.) of the salt in 1 fluidounce (30 Cc.) of water may be given in doses of $\frac{1}{2}$ to 1 fluidrachm (2–4 Cc.), 3 times daily. In substance the dose is from $\frac{1}{10}$ to $\frac{1}{2}$ grain (0.006–0.03 Gm.).

An ointment containing from 2 to 5 grains (0.12–0.30 Gm.) to 1 ounce (30 Gm.) of lard has been recommended as a remedy for enlarged glands.

The remaining salts of barium are rarely employed in medicine, except the oxide, which was formerly recommended as an escharotic, and the carbonate, which was used as a parasiticide in the treatment of certain skin diseases.

The following compounds are more or less employed in medicine, in chemistry, and in the arts:

Barii Acetas.—*Barium acetate*, E.; *Acétate de baryum*, Fr.; *Essigsaurer Baryt*, G. $Ba(C_2H_3O_2)_2 + H_2O$.—Made by neutralizing moderately dilute acetic acid with pure barium carbonate until the solution is slightly acid, and evaporating to the point of crystallization. The crystals are 4-sided prisms soluble in 1 part of water and in 100 parts of alcohol. It is a reagent for the determination of chromic acid, and for the preparation of aluminum mordant in cotton-printing.

Barii Bromidum.—*Barium bromide*, E.; *Bromure de baryum*, Fr.; *Brombaryum*, G. $BaBr_2 + 2H_2O$.—It is obtained on dissolving barium carbonate in hydrobromic acid, and crystallizes in colorless rhombic plates, which dissolve in their own weight of cold water and are freely soluble in alcohol. The salt has a very disagreeable taste.

Barii Carbonas.—*Barium carbonate*, E.; *Carbonate de baryum*, Fr.; *Kohlensaurer Baryt*, G. $BaCO_3$.—It is found native, as witherite, in large quantities in the lead mines at Alston Moor, and at Anglesark in Lancashire, England. It is also met with in Scotland and Sweden. It may be obtained artificially by precipitating a soluble barium salt with an alkali carbonate, or by heating to redness and fusion a mixture of 10 parts of heavy spar (barium sulphate), 2 of carbon, and 5 of potash, and washing the fused mass with water, when barium carbonate is left behind. Its formation is explained by the following equation: $BaSO_4 + C_2 + 2KOH = BaCO_3 + K_2S + CO_2 + H_2O$. Witherite is found in pale-yellowish or grayish fibrous masses or in rhombic crystals varying in specific gravity between 4.3 and 4.56. The artificially prepared barium carbonate forms a soft, white, amorphous or crystalline, tasteless powder. Its

specific gravity is 4.22 to 4.307. It requires more than 15,000 parts of boiling water for solution, but dissolves more readily in solution of chloride and some other salts of ammonium, and is also slightly soluble in some carbonates, and even sulphates. When recently precipitated, it decomposes the solutions of many salts, precipitating the metals either as hydroxides or carbonates. Owing to its solubility in hydrochloric and other acids, it acts as a poison when taken internally. Barium carbonate should be completely soluble, with effervescence, in dilute hydrochloric acid (absence of barium sulphate). The solution is not colored or precipitated by ammonia or hydrogen sulphide (absence of lead and other metals). When the solution is precipitated by excess of sulphuric acid, the filtrate, on being evaporated, should leave no fixed residue (absence of alkalies), and should yield no precipitate with sodium carbonate (absence of calcium and other earths).

Barii Chloridum.—*Baryum Chloratum*, P. G.; *Barium chloride*, E.; *Chlorure de baryum*, Fr.; *Baryumchlorid*, G. $BaCl_2 + 2H_2O$.—It is prepared by dissolving barium carbonate in diluted hydrochloric acid, evaporating the solution, and crystallizing. On the large scale it is obtained sometimes as a secondary product, as in the preparation of ammonium carbonate, or is made from native barium sulphate (heavy spar) by igniting its mixture with charcoal, so as to form barium sulphide, and carbon dioxide, according to the equation: $BaSO_4 + C_2 = BaS + 2CO_2$. The barium sulphide thus obtained is then dissolved in water and boiled with excess of hydrochloric acid, whereby hydrogen sulphide is given off, barium chloride remaining in solution: $BaS + 2HCl$ yields $BaCl_2 + H_2S$. By evaporating the solution the salt is obtained in crystals. Barium chloride exists in colorless, translucent, rhomboidal tables or lamellæ. It is permanent in the air at the ordinary temperature, but loses one-half of its water above 55° C. (131° F.), and becomes anhydrous at 121° C. (249.8° F.). 100 parts of water retain at 105° C. (221° F.) 60 parts, at 40° C. (104° F.) about 41, at 20° C. (68° F.) 35.7, and at 10° C. (59° F.) 34.3 parts of the salt in solution (Mulder). The aqueous solutions are partly precipitated by strong hydrochloric and nitric acids, in which the salt is less soluble than in water. It is insoluble in absolute alcohol, but dissolves in spirit containing water, and imparts to the alcohol flame a yellow color. It possesses the persistently bitter and disagreeable astringent taste of the soluble barium salts. Its solution yields with silver nitrate and with potassium sulphate or dilute sulphuric acid copious white precipitates, which are insoluble in nitric acid. Phosphates, carbonates, and the salts of most organic acids yield with barium chloride precipitates which are insoluble in water, but dissolve in nitric or hydrochloric acid. Barium chloride should be entirely soluble in water (absence of barium carbonate and sulphate), and the solution should not be colored or precipitated by ammonia or hydrogen sulphide (absence of lead and other metals). When precipitated by an excess of sulphuric acid, the filtrate should leave no fixed residue on evaporation (absence of alkalies), and should yield no precipitate with sodium carbonate (absence of calcium and other earths). Alcohol shaken with the powdered salt, then poured off and ignited, should not burn with a red flame (absence of strontium chloride). 1 Gm. of the salt dissolved in 20 Cc. of water should show no blue color with 0.5 Cc. of 5 per cent. potassium ferrocyanide solution.—P. G.

Barii Chromas.—*Barium chromate*, E.; *Chromate de baryum*, Fr.; *Chromsaurer Baryt*, G. $BaCrO_4$.—A lemon-yellow powder, insoluble in water and acetic acid, and soluble or decomposed in hydrochloric, nitric, or sulphuric acid. Obtained by double decomposition between $BaCl_2$ and K_2CrO_4, and used as a pigment as ultramarine yellow, jaune de Steinbuhl.

Barii Dioxidum.—*Barium dioxide, Barium peroxide*, E.; *Peroxyde de baryum*, Fr.; *Baryumhyperoxyd*, G. BaO_2.—Barium dioxide is prepared by conducting oxygen or atmospheric air over barium oxide or hydroxide heated to full redness. It is a heavy, grayish-white or pale yellowish-white, amorphous solid, odorless and tasteless, and permanent in the air. Almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hydrogen dioxide which remains in solution for a considerable time, if the reaction has taken place in the cold and an excess of the acid is present. When heated to a bright-red heat, barium dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium dioxide should be dissolved by diluted hydrochloric acid without leaving more than a trace of residue. If 0.422 Gm. of barium dioxide, in powder, be dissolved as completely as possible in 10 Cc. of ice-cold water, with the aid of a sufficient quantity of phosphoric acid, it should require not less than 40 Cc. of tenth-normal potassium permanganate solution to impart to the liquid a permanent pink tint, corresponding to not less than 80 per cent. of pure barium dioxide (each Cc. of the volumetric solution indicating 2 per cent. of the latter).—U. S., 1890. Barium dioxide is employed in making the official hydrogen dioxide solution. As it often contains iron, calcium, and silica as impurities, which enter the solution of hydrogen dioxide, it is better to use the purified hydrated barium dioxide described below.

Barii Dioxidum Hydratum seu Crystallisatum.—*Hydrated or crystallized barium dioxide.* $BaO_2 + 8H_2O$.—This compound, because of its greater purity, is better suited for the preparation of hydrogen dioxide than the article obtained by heating barium oxide in air or oxygen, as described above. It is prepared by adding finely powdered commercial barium dioxide to 2 per cent. hydrochloric acid until the reaction is just slightly acid, and then adding dilute baryta solution until weakly alkaline; the hydroxides of iron and aluminum, and silica, which are thus precipitated, are filtered off. To the filtrate strong baryta solution is added until a

precipitate no longer forms. The latter, which is crystalline, is filtered, washed with ice-cold water, and dried between filter-paper or preserved moist in well-closed bottles. When dried and heated to 130° C. (266° F.), pure BaO_2 remains as a white, magnesia-like powder.

Barii Hydroxidum.—*Barium hydroxide*, E.; *Oxyde de baryum hydraté*, Fr.; *Baryumhydroxyd, Aetzbaryt*, G. $Ba(OH)_2$.—Barium oxide is prepared by first calcining barium nitrate; the oxide is dissolved in water, and the filtered solution evaporated to dryness and heated to redness. $Ba(OH)_2$ remains as a white crystalline mass or a white powder, specific gravity 4.495, and having a strong alkaline reaction. When a hot concentrated solution is allowed to cool, large clear plates or prisms are formed, of the composition $Ba(OH)_2.8H_2O$, which melt at 80° C. (176° F.) and in dry air lose 7 molecules of water, or 40 per cent., leaving the compound $Ba(OH)_2.H_2O$, which loses its molecule of water only at red heat. The crystallized hydroxide is soluble in 20 parts of cold and 3 parts of hot water. It may also be prepared by adding 224 parts of barium chloride, $BaCl_2.2H_2O$, to a hot solution of 80 parts of sodium hydroxide in 500 parts of water. Barium hydroxide crystallizes out on cooling. The solution of the hydroxide is known as *baryta water*, and is used in analysis to precipitate magnesium and to detect and estimate carbon dioxide, which forms insoluble barium carbonate.

Barii Iodidum.—*Barium iodide*, E.; *Iodure de baryum*, Fr.; *Baryumiodid*, G. $BaI_2.2H_2O$. —It is conveniently made by boiling a solution of iodide of iron with excess of barium carbonate, filtering, and crystallizing. It forms large transparent rhombic prisms, which are very freely soluble in water and alcohol, and when heated melt and become anhydrous.

Barii Nitras.—*Barium nitrate*, E.; *Azotate de baryum*, Fr.; *Salpetersaurer Baryt*, G. $Ba(NO_3)_2$.—Obtained by the action of nitric acid on barium carbonate. Colorless hard octahedral crystals, permanent in the air, with a pungent, slightly bitter taste, soluble in 12.5 parts of water at 15° C. (59° F.) and 3 parts of boiling water, insoluble in alcohol. Strongly heated, it gives BaO. Its solution should be neutral and give no precipitate with silver nitrate (absence of chlorine). Other tests of purity are the same as under Barium Chloride. The salt is used as a chemical reagent and in pyrotechnics to produce a green-colored flame. It easily deflagrates or explodes when rubbed or heated with combustible substances.

Barii Sulphas.—*Barium sulphate*, E.; *Sulfate de baryum, Spath pesant*, Fr.; *Schwefelsaurer Baryt, Schwerspath*, G. $BaSO_4$.—This is a mineral from which other barium compounds are prepared by converting it first into soluble sulphide; on treating its solution with dilute sulphuric acid, barium sulphate is again formed, and this is used under the name of *permanent white* or *blanc fix* for glazing cards and by painters in place of white lead. It is insoluble in water and acids, and is unchanged by hydrogen sulphide, whereas white lead turns yellow under its influence.

Barii Sulphis.—*Barium sulphite.* $BaSO_3$.—Obtained by saturating finely powdered barium carbonate suspended in water with sulphur dioxide. The sediment is filtered and dried on porcelain plates at 25°–30° C. (77°–86° F.). It is a white crystalline powder difficultly soluble in water. Used in paper manufacture.

BELÆ FRUCTUS.—Bael Fruit.

Indian bael, Bengal quince, E.; *Bengalische Quitte*, G.; *Coing de Bengale*, Fr.; *Bél*, Hind.

The dried half-ripe fruit of *Ægle Marmelos* (L.) Correa (*Crataeva M.* L.—Fam. *Rutaceæ*).

Origin.—The Bael tree is indigenous in the Himalayas, and is largely cultivated throughout India, being sacred among the Hindoos and connected in many ways with their mythology and rites. It is of medium size, spiny, and not unlike the orange in appearance. The leaves, and the fresh juice expressed from them, are in native use as being carminative, laxative, and febrifuge, and the root-bark as an antispasmodic.

Description.—The fruit resembles an orange in form, size, and structure, but has a smooth or granular hard rind, like that of a gourd, and its numerous seeds are woolly. It consists of from 10 to 15 cells, the pulp completely filling it. Both the rind and pulp are aromatic, the former much more so. The pulp is sweetish, acidulous, very mucilaginous, and, before maturity, decidedly astringent. When fully ripe, it is somewhat laxative. As occurring in market, it is either entire or cut into sections, the rind brown or gray-brown, 2 or 3 Mm. ($\frac{1}{12}$ to $\frac{1}{8}$ In.) thick, the pulp varying from orange to red-brown in color.

Constituents.—The most abundant is gum, divisible into two portions, the one completely soluble, the other swelling, in water and associated with pectin. The rind contains concrete essential oil. The ripe fruit has been reported to contain 5 per cent. of tannin, but the statement lacks confirmation. It yields nearly 4 per cent. of ash, mostly in the pulp.

Action and Uses.—Bael is said to be astringent, aromatic, and demulcent. It has been especially employed in India in the treatment of diarrhœa and dysentery resulting

from an atonic condition of the mucous membrane of the gastro-intestinal tract. Those who have employed it most state that its administration does not produce constipation, but, on the contrary, that it acts as an aperient.

A liquid extract may be given in the dose of 1 or 2 drachms (4–8 Cc.). A decoction, made by boiling 2 ounces (60 Gm.) of the drug with 1 pint (480 Cc.) of water until 8 ounces (240 Cc.) remain, is frequently given in doses of ½ to 1 ounce (16–30 Cc.), every 2 hours in acute cases, and 3 times daily in those of subacute or chronic type.

BELLADONNA.

Black cherry (*Poison* B. C.), *Deadly nightshade, Doft-berry, Devale* (*Dwale*), *Dway-berry, Great morel, Mod, Mekilwort,* E.; *Belladonna, Tollkirsche, Tollkraut, Wolfskirsche,* G.; *Belladone* (Fr. Cod.), *Morelle Furieuse,* Fr.; *Belladoña,* Sp.

Belladonnæ Folia, *U. S., Br.*—Belladonna Leaves.

Folia Belladonnæ, P. G.

The dried leaves of *Atropa Belladonna* L. (Fam. *Solanaceæ*), yielding, when assayed by the U. S. P. process, not less than 0.35 per cent. of its alkaloids.

Official in most pharmacopœias, though some name the herb, and some specify collection when in flower. The Br. P. names the leaves, but defines as the fresh leaves and branches, collected when in flower. This fresh state should be allowed for, quantitatively, in the preparations, since the drug loses more than three-fourths in drying. The Br. P. calls the extract of this the *Green Extract,* so that no confusion can arise. Several pharmacopœias specify, of the dried drug, that the last fourth shall be rejected in powdering, as valueless.

Origin.—From a tall, stout, widely branched perennial herb, corresponding to Fig. 58. The flowers are of a dark-purple, and the berries are shining and purple-black. The plant grows wild in the greatest abundance through central and southern

FIG. 56.

Atropa Belladonna L.: branch, fruit, seed, and section of seed, the two last magnified.

FIG. 57.

Scopola leaf (½ Nat.).

Europe, and western Asia, and occasionally in other countries, and is the occasion of many serious or fatal poisoning accidents.

It is rather extensively cultivated for drug-production in Germany and England. Statements differ widely as to the relative strength of that of cultivated and of wild origin. The most favorable stage of growth for collection is also in doubt. The character of the

alkaloids, as well as their amount, is apparently subject to change, and until more is known in relation to these, positive statements regarding such questions are inadvisable. Gilpin and Langdon report, as the result of many assays, that the English leaves are usually distinctively superior to the German.

Description.—A much-wrinkled, brownish-green mass of leaves, frequently with more or less of the branchlets and flowers intermixed; leaf-blades from 7 to 20 Cm. (3 to 8 In.) long and 4 to 12 Cm. (1½ to 5 In.) broad, ovate, abruptly and nearly equilaterally narrowed into a rather broad petiole, acute at the summit, entire, thin, nearly smooth, above brownish-green, underneath grayish- or slightly brownish-green, both surfaces whitish-punctate under a lens; toughish; of a slight narcotic odor, greatly increased on moistening, and a bitterish, somewhat acrid, disagreeable taste. The powder is characterized by few hairs and by numerous arrow-shaped crystals of calcium oxalate.

The powder is of a dark-green or often brownish-green color. Its most characteristic element is the large crystal-cells, or "sacs," of the mesophyll, filled with crystal-sand, and visible in all except the finest powders. Even here their broken fragments are usually discernible. The peculiar, very wavy borders of the epidermal cells are also considered characteristic.

Although described as smooth, from their gross appearance, belladonna leaves bear some hairs, especially when young, part of them glandular, others not so. They frequently exhibit perforations, due to the separation of suberous growths. They are readily distinguished from the leaves of Scopola, which are commonly admixed, by the long-tapering base of the latter. All other leaves which have been sold for or admixed with them have toothed margins.

Constituents.—The general nature of the constituents will be considered under Belladonnæ Radix. From that, the leaves differ in the possession of an abundance of chlorophyll, some wax, and an odorous principle which has not been studied, as well as in having somewhat less of total alkaloid. Their use is therefore sometimes open to the objection of producing a green stain and yielding a rank odor. Kunz–Krause reports upon a "belladonna-balsam" resembling balsam of Peru, which is obtained in working up belladonna leaves upon a large scale.

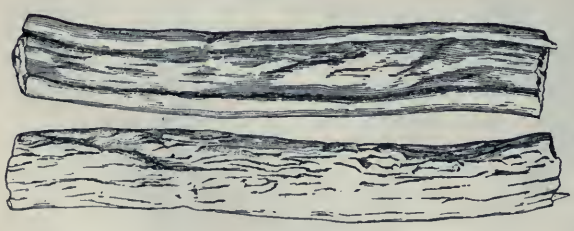
Belladonnæ Radix, *U. S.*, *Br.*—Belladonna Root.

The dried root of *Atropa Belladonna* L. (Fam. *Solanaceæ*), yielding, when assayed by the U. S. P. process, not less than 0.5 per cent. of its alkaloids.

Origin.—This has been discussed under Belladonnæ Folia, and the remarks there made concerning the wild and cultivated product and the season of collecting, apply here also. The Br. P. requires that the root be collected in the autumn.

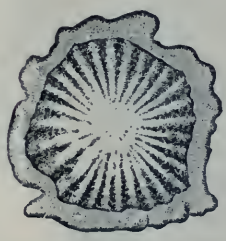
Description.—In cylindrical or slightly tapering, lightly longitudinally wrinkled pieces, 1 to 2.5 Cm. (⅖ to 1 In.) thick, the bark slightly incurved at the edges of roots which have

Fig. 58.



Belladonna root (Nat.).

Fig. 59.



Belladonna root: cross-section.

been split before drying; externally pale brown-gray, dusty or mealy, the outer layers of the periderm rather soft, frequently abraded, and thus showing lighter patches; fracture sharp, emitting a characteristic puff of dust, the fractured surface whitish, mealy, nearly smooth, finely and imperfectly radiate near the bark; nearly inodorous; taste sweetish, then bitterish and strongly acrid.

Tough and woody roots, of splintery fracture, as well as the short woody rhizome, knotty crown, and hollow-stem bases, should be rejected.

The powder is of a pale-gray or dirty-white color. It contains minute crystals or crystal-sand similar to those of the leaves, coming from the cortical cells. Both bast-fibers and stone-

cells are practically wanting, though the former have exceptionally been found. The vessels are highly porous, some with bordered pores. The abundant starch-grains are either simple or compound, about 5 to 10 mikrons in diameter, the hilum central or nearly so, small, entire, or faintly radiate, the concentric lines rather faint.

Belladonna-root is preferred when between 2 and 4 years of age, of the thickness of a man's finger, when it breaks with a mealy fracture. When much younger, it breaks with a horny or resinous fracture, and, besides containing less alkaloid, the latter is by many believed to be of a different nature. When much older, it becomes hard and woody, and the percentage of alkaloid is small. A good root contains alkaloid in the parenchymatic tissue of all parts, though mostly in the bark ; but in a woody root it is almost exclusively in the bark. We are frequently cautioned against accepting roots which have been peeled, the peelings used in the manufacture of atropine, but this article seems to have disappeared from the market. It would certainly be very inferior.

The root is generally believed to be richest in the late summer or autumn, and this is the season when it is mostly collected. E. Schmidt found nearly 3 times as much alkaloid in the fall as in the spring, while assays by Kremel showed nearly 4 times as much in the spring as in the fall. Kremel also reported that drying reduced the amount nearly one-half, and that there was a steady annual loss of about a tenth while keeping the drug. All but the smaller roots are split to insure drying without damage.

Adulterants.—There is but one root which bears a close resemblance to belladonna, yet a number have been used for purposes of adulteration. Medicago root has been frequently used for the purpose. It is tough and flexible, with a thin bark, lacks the snapping fracture with its puff of dust, exhibits a more regularly radiate appearance, and its stem-bases are not hollow. We have seen wild mallow roots admixed, but they also have a tough fracture. Scopola is easily detected if the rhizome be present, but if only its roots are used, the resemblance is extremely close. These roots are usually darker, more of a brown than of a gray, the surface less dusty and marked by transverse rows of very small, slightly transversely elongated root-scars of a light color. On fracture, the yellow color is seen to be more uniformly distributed toward the center, and the radiation is broader. Holmes has reported encountering adulteration with the root of a species of Phytolacca, easily recognized by its interrupted wood-wedges, forming concentric zones, as in ordinary poke-root.

Constituents.—The important constituents of belladonna root are a rather large amount of starch, mostly in the autumn, very little in early summer ; sugar, more especially in the spring, when there is almost no starch ; albumin, and a fluorescent principle which has passed under the name of *atrosin*, but is now identified as β-methyl-æsculetin. There is about 14 per cent. of ash. The important and active constituents are alkaloids varying in amount from 0.2 to about 1 per cent., the average being probably 0.55 to 0.6 per cent. The determination of this percentage has been a matter of great difficulty, as attested by the extreme diversity found in the reports of accomplished workers during the last decade, but the above statement may be regarded as fairly indicated by a comparison of the most trustworthy statements. With these, even more than with most other alkaloids, it is true that different results are obtained by different methods, and even with the same method applied by different experimenters ; and the value of comparative assays depends in a high degree upon the care taken to preserve uniformity in the operations.

As to the character of the alkaloids, our information is even more contradictory. That changes therein are liable to occur in the manipulation is well established, hyoscyamine being readily converted into atropine by a number of conditions. That such changes occur during the aging of the plant has also been generally believed, but appears clearly untrue. We are not disposed, in the present state of knowledge of this subject, to make positive statements concerning the identity of some of these alkaloids or the relative amounts of others. Almost all of the alkaloid is a mixture of atropine and hyoscyamine, both elsewhere discussed under those titles. As extracted, the former greatly predominates, but it is not certain that this is true as they exist in the living plant, or even in the dried root, the change of hyoscyamine into atropine in the meantime being at least possible.

A series of records by Gilpin and Langdon indicate that the volumetric method of assay gives much lower results than the gravimetric. One of the most carefully

conducted investigations, involving extraordinary measures of precaution, from the selection of the drug through all the processes of manufacture and alkaloidal examination, indicated that much more than half of the total alkaloid in these commercial roots is hyoscyamine. The other alkaloids are *scopolamine*, *atropamine* (or *aposterpine*), and *belladonnine*, the last an artificial derivative of the preceding. They are present in such small amounts as to probably not modify appreciably the action of the drug.

The U. S. P. requires that, when assayed by the following process, belladonna-leaves shall yield not less than 0.35 per cent. and belladonna-root not less than 0.5 per cent. of the alkaloids present in the drug:

Assay of Belladonna.—Belladonna-leaves or root, in No. 60 powder, 10 Gm.; chloroform, ether, normal sulphuric acid, ammonia-water, distilled water, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin test-solution, or iodeosin test-solution, each a sufficient quantity. Place the belladonna-leaves or root in an Erlenmeyer flask, and add 50 Cc. of a mixture of chloroform 1 part and ether 4 parts (by volume). Allow the flask to stand 10 minutes after inserting the stopper securely, then add 2 Cc. of ammonia-water mixed with 3 Cc. of distilled water, and shake the flask well at frequent intervals during 1 hour. Then transfer as much as possible of the contents of the flask to a small percolator, which has been provided with a pledget of cotton packed firmly in the neck and inserted in a separator containing 6 Cc. of normal sulphuric acid diluted with 20 Cc. of distilled water. When the liquid has passed through the cotton, pack the belladonna-leaves firmly in the percolator with the aid of a glass rod, and having rinsed the flask with 10 Cc. of the chloroform-ether mixture, transfer the remaining contents of the flask to the percolator, by the aid of several small portions (5 Cc.) of the chloroform-ether mixture, and continue the percolation with successive small portions of the same liquid (in all 50 Cc.). Next, shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid solution into another separator. Add to the chloroform-ether mixture 10 Cc. of the sulphuric acid mixture of the same strength as that previously used, agitate well, and again draw off the acid solution into the second separator; repeat this operation once again, drawing off the acid solution as before; introduce into the acid solutions contained in the second separator a small piece of red litmus-paper, then add ammonia-water until the liquid is distinctly alkaline, and shake out successively with three portions (15, 15, 5 Cc.) of chloroform; collect the chloroform solutions in a beaker, place it on a water-bath containing warm water, and allow the chloroform to entirely evaporate. Dissolve the residue in 3 Cc. of ether and let this also evaporate completely. To the alkaloidal residue add 3 Cc. of tenth-normal sulphuric acid and 5 drops of hematoxylin test-solution (or iodeosin test-solution), then titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of cubic centimetres of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 3 (the 3 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.0287, and this product by 10; the result will be the percentage of total alkaloids contained in the belladonna-leaves or root.

The figure 0.0287 represents the weight in grammes of alkaloids (mainly atropine) required to neutralize 1 Cc. of tenth-normal sulphuric acid.

Pharmaceutical Preparations.—Of the leaves: TINCTURE OF BELLADONNA, U. S. P.; EXTRACT OF BELLADONNA, U. S. P. Of the root: FLUIDEXTRACT OF BELLADONNA, U. S. P.; LINIMENT OF BELLADONNA, U. S. P.

Action and Uses.—As has been pointed out, belladonna belongs to a very large class of drugs, the physiological effect of each of which is nearly identical. When taken in overdose, it produces dryness of the throat, dilatation of the pupils, sometimes difficulty in swallowing, and a flushed face, which is peculiar in that the flush is over each cheek-bone, while the skin at the corners of the nose and about the angles of the mouth is often unduly white. The skin is also apt to be hot and dry, and the bodily temperature may be raised as much as 2 degrees. In susceptible persons an active, talkative delirium often becomes quite marked, and double vision may be present owing to the influence of the drug upon the oculomotor nerve, whereby the action of the extra-ocular muscles is impaired. In some instances the flushing of the skin of the face extends all over the body, and a rash closely resembling that of scarlet fever is developed which may be so severe as to be followed by desquamation. The pulse is apt to be rapid and running, and the respirations quickened. Death very rarely follows belladonna-poisoning, because it is a drug which is not exceedingly lethal in its influence, and also because it is very rapidly destroyed and eliminated from the body, escaping chiefly through the kidneys in such considerable quantities that if the urine of a poisoned person be dropped in the eye of one of the domestic animals it will cause mydriasis. The dilatation of the pupil which is seen under large medicinal or poisonous doses of belladonna depends upon depression of the peripheral ends of the oculomotor nerves and stimulation of the peripheral ends of the sympathetic nerves. The drug also probably depresses the contractility of the circular fibers in the

iris, and increases the activity of the radiating fibers. The loss of accommodation under the influence of belladonna is largely due to its influence upon the oculomotor nerves and the ciliary muscles, and part of the mydriasis may be due to the effect of the drug upon the bloodvessels of the iris. Dropped into the eye, it produces wide dilatation of the pupil; but its alkaloid, atropine, is usually used for this purpose. The drug, whether given internally or used locally, increases intra-ocular tension, and is contraindicated in glaucoma. Belladonna acts as a stimulant of the vasomotor center and raises the arterial pressure thereby, although upon the capillaries of the skin it seems to cause vascular relaxation.

Belladonna is used in medicine for the purpose of checking excessive secretion in cases of profuse sweating, in serous diarrhœa, and for profuse urinary flow not depending upon diabetes mellitus. It is also sometimes employed to check excessive ptyalism. In checking excessive secretion, it acts by depressing the ends of the nerves supplying the glands involved. It is a remedy of inestimable value in collapse complicating injuries or acute diseases, and has been largely employed for the purpose of relieving muscular spasm when this spasm involves unstriped muscular tissues. Thus, it is used in purgative pills to prevent griping, and in cases of incontinence of urine to allay irritability of the bladder. It is also sometimes employed as a sedative for the purpose of relieving spasm in renal and gallstone colic, but under these circumstances it is usually administered with opium or its alkaloid, morphine.

Still another condition of spasm in which it is very valuable is true spasmodic asthma, in which it does good by acting upon the muscular fibers of the bronchial tubes and upon the walls of the bloodvessels in the bronchial mucosa, and by diminishing the activity of the pneumogastric nerves. Often belladonna leaves are smoked in cigarettes for this purpose. It has also been used in spasmodic croup with asserted advantage, and in certain types of nervous vomiting it is said to be useful.

Locally applied, the extract is valuable in suppositories in the treatment of hemorrhoids, and in the form of atropine, when dropped into the eye, it is a necessity in the treatment of iritis to prevent adhesions. At one time it was thought that belladonna and atropine were powerful antagonists to opium, and were to be considered as the physiological antidotes for that drug, but their usefulness in opium-poisoning is now recognized as not very great. Belladonna has been employed for the relief of various forms of pain, and sometimes does good in neuralgia, but is not of much value unless the pain depends upon spasm.

The dose of the tincture of belladonna is from 8 to 20 minims (0.50–1.30 Cc.); of the fluidextract, from 1 to 10 minims (0.05–0.60 Cc.); and of the solid extract, grain $\frac{1}{4}$ (0.015 Gm.).

Belladonna de Pais, of Mexico, is *Nicandra physaloides* L. (see SOLANACEÆ).

BENZALDEHYDUM, *U. S.*—Benzaldehyde.

Oleum amygdalarum æthereum artificiale; Oleum amygdalarum æthereum sine acido prussico.—Synthetic oil of bitter almond, E.; *Aldéhyde benzoique*, Fr.; *Benzaldehyd, Künstliches Bittermandelöl*, G.

Formula, C_7H_6O or $C_6H_5.COH$. Molecular weight, 105.25.

An aldehyde produced artificially, or obtained from oil of bitter almond or other oils, and containing not less than 85 per cent. of benzaldehyde. It should be kept in small amber-colored, well-stoppered bottles.—U. S.

Benzaldehyde was first prepared in a pure state by Liebig and Wöhler in 1837, who ascertained its composition and studied its relation to benzoic acid. Having first been isolated from bitter almond oil, it was designated pharmaceutically as *oleum amygdalarum æthereum sine acido prussico*. Because of its relation to the benzoyl radicle, C_6H_5CO, it was designated benzoyl hydrate. Inasmuch as it is the aldehyde corresponding to benzoic acid, C_6H_5COOH, it is commonly designated benzaldehyde. It is now prepared on a large scale from toluene, $C_6H_5CH_3$, the hydrocarbon underlying benzyl alcohol, $C_6H_5CH_2OH$, benzaldehyde, C_6H_5CHO, and benzoic acid, C_6H_5COOH.

Preparation.—(A) FROM BITTER ALMOND OIL.—1. In order to remove the hydrocyanic acid, oil of bitter almonds is shaken with milk of lime and a small quantity of solution of iron sulphate, set aside for several days, and the mixture distilled with water vapor. The hydrocyanic acid is thereby converted into Prussian blue.

2. The benzaldehyde can likewise be isolated by shaking the oil with two or three times its weight of freshly prepared concentrated solution of sodium acid sulphite, whereby it is converted into the crystalline benzal hydroxysulphonate of sodium, $C_6H_5CH(OH)\text{-}SO_2ONa$. The crystalline magma is drained, washed with cold alcohol, and the benzaldehyde regenerated by treatment with strong sodium carbonate solution. The regenerated aldehyde is rectified either by direct distillation or by distillation with steam.

(B) From Toluene.—This hydrocarbon is first converted, by direct substitution, into benzyl chloride or benzal chloride, either of which may be used for the preparation of benzaldehyde.

1. Benzyl choride, $C_6H_5CH_2Cl$, is heated with barium nitrate and water while passing a current of CO_2 through the mixture. The benzyl nitrate resulting decomposes with the formation of benzaldehyde and oxides of nitrogen.

2. Benzal chloride can be converted directly into benzal glycol, $C_6H_5CH(OH)_2$, and benzaldehyde by heating it with caustic soda or milk of lime, or with water under pressure. The benzaldehyde resulting from either method can be purified through the sodium-acid-sulphite addition product, as directed above (A, 2).

Properties.—Benzaldehyde is a colorless, strongly refractory liquid, which possesses the odor peculiar to bitter almond oil and a burning aromatic taste. Its specific gravity is about 1.045 at 25° C. (77° F.); it boils at 179° to 180° C. (354.2°–356° F.), and is optically inactive. It is sparingly soluble in water (about 1 : 300), but readily soluble in most organic solvents. When exposed to oxygen it readily oxidizes to benzoic acid, $C_6H_5CHO + O = C_6H_5COOH$, hence it should be kept in small, well-stoppered bottles. Unlike the natural bitter almond oil, it is not poisonous.

Tests.—The absence of hydrocyanic acid can be ascertained by dissolving 10 drops of the aldehyde in question in a little alcohol. This alcoholic solution is shaken with a few drops of a strong solution of sodium hydroxide, then with a little ferrous sulphate test-solution. Finally, hydrochloric acid is added in excess. The formation of a blue precipitate or blue color would indicate the presence of hydrocyanic acid. Benzaldehyde prepared from toluene is apt to contain traces of the intermediate derivation products unless carefully rectified. The presence of chlorine can be ascertained by burning the aldehyde in question, whereby the chlorine is converted to hydrochloric acid. This combustion is best effected by burning a taper of filter-paper saturated with the aldehyde in a small porcelain dish covered by a large beaker, the inner surface of which has been moistened with distilled water. After the vapors have had time to be absorbed by the moisture, the beaker is rinsed with a little distilled water, the liquid filtered, and the filtrate tested with silver nitrate test-solution in the usual manner. A turbidity or a white precipitate of silver chloride would indicate the presence of chlorine.

Assay of Benzaldehyde.—Benzaldehyde is readily oxidized to benzoic acid, especially when poorly kept. In ordinary containers the oxidation sometimes proceeds so far that the benzoic acid will crystallize out. However, since the benzoic acid constitutes no serious impurity, the U. S. Pharmacopœia demands no higher percentage of benzaldehyde than 85 per cent. The amount can be determined by the following assay process. Rosolic acid is preferable as indicator to phenolphthalein employed in the U. S. P. assay: Introduce into a tared 150 Cc. flask, by means of a pipette, 12 drops of benzaldehyde, and note the exact weight of the latter; then add 10 Cc. of purified petroleum benzin and afterward 20 Cc. of distilled water with 6 drops of phenolphthalein test-solution, and neutralize the solution exactly by the addition of tenth-normal sodium hydroxide solution, agitating the flask thoroughly. Add from a burette, gradually, a solution of sodium sulphite (1 in 5), alternating with half-normal hydrochloric acid from a second burette, until 10 Cc. of the sodium sulphite solution have been added, and enough half-normal hydrochloric acid to maintain the neutrality of the mixture; after adding a few drops of phenolphthalein test-solution, and agitating the flask frequently, allow it to stand 2 hours to insure a permanent condition of neutrality, and then note the number of cubic centimetres of the half-normal hydrochloric acid used. Carry out a blank test, identical with the foregoing, except that the benzaldehyde is omitted, and note the amount of half-normal hydrochloric acid consumed. Subtract the number of cubic centimetres required in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.0526 Gm. of benzaldehyde. To find the percentage, multiply the above difference by 0.0526, and this product by 100, and divide by the weight of the benzaldehyde taken.—U. S.

Action and Uses.—Benzaldehyde, or artificial oil of bitter almonds, is used largely as a flavoring agent instead of the natural oil. Being devoid of hydrocyanic acid, it is not poisonous except in very large quantity.

BENZENUM.—Benzene (sometimes called Benzol).

Benzol, Br.; *Phenyl hydride*, E.; *Benzole*, *Benzène*, Fr.; *Benzol*, *Steinkohlenbenzin*, G.

Formula, C_6H_6. Molecular weight, 77.46.

A mixture of homologous hydrocarbons obtained from light coal-tar oil. It contains about 70 per cent. of benzene, C_6H_6, and 20 to 30 per cent. of toluene, $C_6H_5.CH_3$. —Br.

The discovery of benzene is credited to Faraday, who found it in the condensed liquid from oil gas, and it was observed next by Mitscherlich as a product of the distillation of benzoic acid with lime, and later as a constituent of coal-gas tar by A. W. Hofmann.

There is much confusion in the use of the term *benzene*, a substance of definite composition, with the term *benzin*, a liquid consisting of various hydrocarbons obtained from petroleum. The term *benzene* should be applied solely to the product from *coal-tar* boiling at 80.4°–81° C. (176.7°–177.8° F.), and having the definite composition C_6H_6. Although the ending "ol" is confined to the names of the alcohols and phenols, and the more appropriate ending "ene" used for the hydrocarbons proper, the term *benzol* is used commercially for some coal-tar products to designate various mixtures of benzene with *toluene*, *xylene*, *cumene*, etc., the grades being designated and sold according to percentage content of volatile matter distilling below 100° C. (212° F.). Thus 50°, 70°, 90° benzol yield the respective volume per cent. of distillate before the thermometer registers 100° C. during the distillation.

Preparation.—The purest form of benzene is obtained by the dry distillation of benzoic acid mixed with an excess of lime, and purifying the oily distillate by further treatment with solution of an alkali hydroxide and subsequent rectification. The product is the "Benzolum ex acido benzoico." Benzene is largely obtained from *coal-tar*, one of the secondary products of coal-gas manufacture: on subjecting it to distillation water and ammonia pass over, accompanied by a brown oily liquid (8 or 10 per cent. of the tar), known as *light oil*, because it floats on water. Subsequently *dead oil* is obtained as an oily liquid heavier than water, and containing aniline, quinoline, naphthalene, carbolic acid, etc.; the residue in the retort constitutes pitch, and is used in place of asphaltum. The light oil contains mainly *benzene*, *toluene* (C_7H_8), *xylene* (C_8H_{10}), and *isocumene* (C_9H_{12}), and after rectification to free it from some dead oil is known in commerce as *coal-naphtha*, which owes most of its disagreeable odor to volatile bases removable by agitation with dilute sulphuric acid. The hydrocarbons are separated from one another by repeated fractional distillation until liquids of a nearly constant boiling-point are obtained. The fraction boiling near 80° C. (176° F.) consists chiefly of benzene, that with the boiling-point 110° C. (230° F.) of toluene, that distilling near 140° C. (284° F.) of xylene, and the portion coming over near 170° C. (337° F.) of isocumene. The benzene may be further purified by exposing it to a low temperature and expressing the portion remaining liquid. The impurities commonly found in commercial benzene are acetylene, thiophene, carbon disulphide, and the homologues toluene, xylene, etc.

Properties.—At the ordinary temperature benzene is a thin, colorless, very inflammable liquid, of considerable refractive power and strong odor of coal-gas; but when obtained from benzoic acid it has a peculiar aromatic odor and a sweetish aromatic taste. It has the density 0.899 at 0° C. (32° F.) and 0.884 at 15° C. (59° F.), congeals at the freezing-point of water, melts again at 5.5° C. (42° F.), and boils at 80.5° (177° F.). The Br. P. requires that benzol shall begin to distil at 80° C. (176° F.), and that 90 per cent. of the whole shall pass over at a temperature below 100° C. (212° F.), and should wholly distil below 120° C. (248° F.). It is nearly insoluble in water, but readily soluble in 4 parts of alcohol, in methyl alcohol, ether, acetone, and chloroform; it dissolves some phosphorus, sulphur, and iodine, and considerable quantities of fats, volatile and fixed oils, caoutchouc, gutta-percha, some resins and alkaloids (quinine). With antimony trichloride W. Smith and G. W. Davis (1882) obtained a colorless crystalline compound having the composition $3SbCl_3.2C_6H_6$, and on exposure becoming opaque and liquefying. It is readily converted to nitrobenzene by the action of nitric acid.

Tests.—To distinguish it readily from petroleum *benzin*, Pusch (1875) recommends iodine, which dissolves in benzin with a raspberry-red and in benzene with a

violet-red color; the first color is so intense that a small admixture of benzin can be recognized by neutralizing the violet tint. It should boil and evaporate completely between 80° and 85° C. (176° and 185° F.), and when shaken with sulphuric acid should not acquire a dark color. On shaking 5 Cc. of benzene with 1 Cc. of sulphuric acid and 1 drop of fuming nitric acid, no green or blue tint should be produced; or if a small quantity of isatine be added in place of the nitric acid, no blue color should be developed (absence of thiophene). If 1 Cc. of benzene be cautiously poured onto 5 Cc. of fuming nitric acid, it dissolves, disengaging brown fumes, and on the addition of water separating oily globules of nitrobenzene, recognized by the odor of oil of bitter almond (distinction from benzin). It should congeal at 0° C. (32° F.), the crystals melting again at + 4° C. (39.2° F.) (distinction from benzin, which does not solidify). If 1 Cc. of the sample is thoroughly agitated with 20 Cc. of pure concentrated sulphuric acid, the discoloration, if any, should not exceed a pale straw-yellow. Not more than 0.5 Cc. of saturated bromine water should be required to impart a persistent (3–5 minutes) yellow tint when shaken with 10 Cc. of benzene. Commercially benzene is assayed by the process of fractional distillation (Allen's *Org. Anal.*, vol. 2, p. 496), the different fractions being matters of contract, the proportion by volume which passes over below and at a given temperature being called the "strength" of the sample at that temperature.

Action and Uses.—Because of its narcotic properties, benzol has been recommended by inhalation in the treatment of pertussis. It was formerly employed by the stomach as a remedy for trichiniasis, and its local application was said to do good in many parasitic skin diseases; it is, however, rarely used at the present time. The drug possesses antifermentative properties resembling those of phenol, and may be employed in the treatment of flatulent dyspepsia. Benzene was at one time suggested as a general anæsthetic; however, the fact that it does not cause muscular relaxation, but, on the contrary, produces muscular tremors and sometimes violent convulsions, and that the preliminary excitement is very great, renders it unfit for such a purpose. Where poisonous amounts are ingested with suicidal intent or accidentally inhaled by workmen, it occasions vertigo, mental aberration, delirium and tonic convulsions, followed by deep sleep. In fatal poisoning by this drug petechial spots are frequently noted, which Sauterson states are the result of fatty degeneration of the bloodvessels.

The ordinary dose of benzol is from 5 to 10 minims (0.3–0.6 Cc.), either in capsules, in emulsion, or on sugar. As much as 50 minims (3.3 Cc.) have been given without deleterious effect, but ordinarily that quantity should not be employed. When employed locally, benzol may be mixed with soapsuds in the proportion of 1 part of the former to 9 parts of the latter.

BENZINUM, *U. S.*—Petroleum Benzin.

Benzinum petrolei, P. G.; *Æther petrolei.—Benzin, Petroleum ether*, E.; *Esprit (Naphté, Éther) de pétrole*, Fr.; *Petroleumbenzin, Petroläther, Benzin*, G.

A purified distillate from American petroleum, consisting of hydrocarbons chiefly of the marsh-gas series [C_5H_{12}, C_6H_{14}, and homologous compounds]. Benzin should be carefully kept in well-stoppered bottles or tin cans, in a cool place, remote from lights or fire.—U. S.

Preparation.—The lower hydrocarbons present in American petroleum are separated from the heavier compounds by fractional distillation, and from all the lightest hydrocarbons by fractional condensation (see PETROLEUM). It is purified by agitation with sulphuric acid, which removes most of the disagreeable odor of the crude benzin. The peculiar sulphurous odor may be removed by treatment with lime, or better by washing it with an aqueous solution of potassium dichromate and sulphuric acid, and thorough subsequent washing with water. The method suggested by Beringer (see BENZINUM PURIFICATUM), in which the benzin is shaken with an acid solution of potassium permanganate, is even more effective,

Since *pentane*, C_5H_{12}, boils at 38° C. (100.4° F.), and *hexane*, C_6H_{14}, at 70° C. (158° F.), it is evident that the benzin of the U. S. P., boiling-point 45°–60° C. (113°–140° F.), consists principally of pentane, while that of the P. G., boiling-point 50°–75° C. (122°–167° F), contains much hexane with variable quantities of pentane and *heptane*, C_7H_{16}, the latter boiling at 98° C. (208.4° F.).

Properties.—Benzin is a transparent, colorless, diffusive liquid of a strong characteristic odor slightly resembling that of petroleum, but much less disagreeable; neutral in reaction; insoluble in water, soluble in about 6 parts of alcohol, and readily so in ether, chloroform, benzene, volatile oils, and fixed oils, with the exception of castor oil. It is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently. It has a specific gravity of from 0.638 to 0.660 at 25° C. (77° F.) (0.640 to 0.670 at 15° C., P. G.), and boils at 45° to 60° C. (113°–140° F.) (50° to 75° C. = 122°–167° F., P. G.).

Tests.—If 5 drops of petroleum benzin are added to a mixture of 40 drops of sulphuric acid with 10 drops of nitric acid in a test-tube, the liquid warmed and set aside for half hour, and then diluted in a shallow dish with twice its volume of water, it should not have the bitter-almond-like odor of nitrobenzene (difference from and absence of benzene).—U. S. Benzene being much higher in price than benzin, adulteration of the latter with the former is not likely to occur. For special tests for distinguishing benzin from benzene, see BENZENUM.

Action and Uses.—Scabies, favus, and other parasitic diseases are said to be benefited by the application of benzin. As it possesses local anæsthetic properties, it has been used in superficial neuralgia in the form of a spray. Its vapor when inhaled is said to be of value in the treatment of whooping-cough.

BENZINUM PURIFICATUM, *U. S.*—Purified Petroleum Benzin.

Ether de pétrole purifié, Fr.; *Gereinigter Petroläether*, G.

Preparation.—Potassium permanganate, 10 Gm.; sodium hydroxide, 2 Gm.; sulphuric acid, 60 Cc.; petroleum benzin, 1000 Cc.; water, a sufficient quantity. Add the acid to 550 Cc. of water, and when the mixture has become cold, pour it into a bottle having the capacity of about 2 liters. Add 8 Gm. of potassium permanganate and agitate until it is dissolved, then add the petroleum benzin, in four portions, shaking the liquid after each addition. Allow the liquids to remain in contact for 24 hours, shaking the bottle at frequent intervals; then decant the petroleum benzin into another bottle of the same capacity, and having dissolved 2 Gm. of potassium permanganate in 240 Cc. of water in which the sodium hydroxide has previously been dissolved, mix the liquids and agitate the mixture frequently during several hours. Finally, repeat the washing with water and again decant the petroleum benzin.—U. S.

Commercial petroleum benzin is contaminated with sulphur compounds and other impurities which it is intended to remove by the official method of purification. If the purified product is intended for use in plant analysis and similar work, it may be best to distil the same, collecting that portion passing over between 45° and 50° C. (113° and 140° F.).

Properties and Tests.—On evaporating 10 Cc. of purified petroleum benzin from a piece of clean filtering paper, no greasy stain should remain and the odor should not be disagreeable or notably sulphuretted; no residue should be left upon evaporating purified petroleum benzin from a warmed dish (absence of heavy hydrocarbons). When it is boiled for a few minutes with one-quarter its volume of spirit of ammonia and a few drops of silver nitrate test-solution, the ammoniacal liquid should not turn brown (absence of pyrogenous products and sulphur compounds). Purified petroleum benzin should have an ethereal or faint petroleum-like odor, and should respond to the tests given under PETROLEUM BENZIN.—U. S.

Action and Uses.—Benzin may be employed as a parasiticide in the treatment of scabies and pediculosis. It has also been used locally in tinea tonsurans, scabies, sycosis, etc. It is an ingredient of many of the household insecticides. Internally it is rarely administered, but if taken in a large quantity it produces an intoxication similar to that of alcohol, and may cause vertigo, unconsciousness, convulsions, and death.

BENZOINUM, *U. S.*, *Br.*—Benzoin.

Benzoé, P. G.; *Resina benzoe, Asa dulcis. Gum Benjamin*, E.; *Benjoin*, Fr.; *Benjui*, Sp.; *Benzoino*, F. It.

A balsamic resin obtained from *Styrax Benzoin* Dryander, and from another unknown species of Styrax (Fam. *Styraceæ*).

Origin.—The species named is a handsome, medium-sized tree, indigenous in Borneo Sumatra, Java, and other of the East India islands, where it is also cultivated. I yields the *Sumatra benzoin.* The tree of the neighboring mainland, yielding the *Sian benzoin,* is doubtless a distinct species, but is of very similar appearance. Siam benzoi is obtained by making a circle of notches through the bark of the trunk, into which th substance, caused to be produced as a result of the wounding, chiefly by tannin-trans formation, exudes. After 3 months this is hard and dry, and is picked out with th point of a knife or a sharp stick, and collected in baskets, being afterward assorted as t size, cleanness, and quality, the larger "tears," "marbles," or "almonds," bringing higher price. The largest and cleanest is called *slua,* the poorest, *mun,* and there is a intermediate or ordinary class recognized by the natives. It can be collected at an season, but the other occupations of the people cause collection to occur chiefly betwee July and November. Sumatra benzoin apparently exudes in the same way, but th tears come massed together with an interstitial resinous substance, so as to form a cake The origin and nature of this matrix are unknown. It is claimed to be that portion o the juice which will not form in tears, and it is said that its amount increases with th number of years that the tree has been tapped, so that the product of the first years con tains more tears and is of a better quality. On the other hand, it appears not impossibl that this amorphous substance originates in a different plant. A very inferior quality containing no tears, called "foots," is scraped from the bark of the exhausted trees whe they are cut down. As originally produced, benzoin is sold to the exporters, who pa tially soften it by heating and pack it solidly into strong boxes. Besides the natura impurities, in the form of twigs, bark, and splinters, large amounts of adulteratin material often are added, chiefly earthy matter, resulting in a product characterized a "drossy." The foreign matter is mostly put into the center, with clean superficial po tions, thus known as "false packed." Large stones were formerly imbedded, this pra tice having resulted in the habit of splitting the cakes diagonally before accepting then Penang benzoin is a form very similar to Sumatra, but having a strong odor of storax.

Description.—In pebble-like bodies or "tears," mostly 0.5 to 5 Cm. (0.2 to 2 In.) long an about one-fourth as thick, lightly flattened, straight or curved, yellowish to rusty-brown exte nally, milky-white on fresh fracture, separate or very slightly agglutinated (Siam benzoin) (Sumatra benzoin) imbedded in a dry resinous mass, which varies from reddish-brown to re dish-gray or gray-brown, is opaque or slightly translucent and more or less sparkling. Whe heated, benzoin gives off fumes of benzoic acid. It has an agreeable balsamic odor (vanill like in the Siam variety), and a rather disagreeable, slightly acrid taste.

After the removal of the bark and other vegetable tissue, the remainder, not less than 7 per cent., should dissolve in 5 times its weight of alcohol, and in solutions of the fixed alkalie The ash should not exceed 2 per cent.

Dieterich gives the saponification number as between 180 and 240 (Siam, 220 to 240).

When benzoin is boiled with milk of lime, the hot filtrate should not give off th odor of oil of bitter almond on the addition of test-solution of potassium permanganat (absence of cinnamic acid). For determining the presence of cinnamic acid, the tinctur of benzoin may be precipitated by hot water, filtered from the resin, and the filtrat treated with a solution of potassium permanganate or chlorinated lime; or the benzoi may be triturated with peroxide of lead and the mixture boiled with water.

Constituents.—The Sumatra benzoin contains from 10 to 20 per cent. of free benzoi and cinnamic acids, the latter in small proportion, or even wanting, 2 to 3 per cent. o styracin, 0.1 to 1 per cent. of vanillin, a little styrol and benzaldehyde, 1 per cent. of pheny propyl cinnamate, and 75 per cent. of the cinnamic esters of benzoresinol and resinotann ($C_{18}H_{20}O_4$). Of these esters, 92.6 per cent. are those of resinotannol, and the rest o benzoresinol, and their yield of cinnamic acid is 33 per cent. of their weight. Sia benzoin contains less free benzoic acid, little or no cinnamic acid, more vanillin (up t 1.5 per cent.), 5 per cent. of benzoresinol benzoate, and 57 per cent. of resinotannol be zoate. Ludy found that the Penang variety varied from much benzoic and little ci namic, to much cinnamic with little benzoic. Benzoin also contains traces of volatile oi fragments of bark and wood amounting to from 8 to 30 per cent., and other impuritie the Siam variety being the purest and least variable.

Substitutes.—Besides the adulterants mentioned above, several substances are use as substitutes. *Palembang benzoin,* which is very rarely seen in our market, is almost quite free from tears, is of a uniform pale reddish-brown and a peculiar opalescent luste

and has little odor. It contains considerable moisture, to which its opalescence is probably due, and it readily becomes mouldy. Holmes has shown it to be derived from *S. benzoin*. Its peculiarities may be due to the method of preparation. It contains benzoic acid, but no cinnamic acid nor vanillin. While its origin would include it in the official definition, it is excluded by the description.

An aromatic exudate used as incense in the East Indies under the name of *False benzoin*, is obtained from *Buceras angustifolius* (Jacq.) Lyons (*Terminalia a.* Jacq.; *T. Benzoin* L. f.; *Catappa B.* Gærtn.), a good-sized tree of Mauritius, of the family *Combretaceæ*. This substance bears little resemblance to benzoin.

Pharmaceutical Preparations.—Tincture of Benzoin, U. S. P.; Compound Tincture of Benzoin, U. S. P.

Action and Uses.—Benzoin is a stimulating expectorant, but is rarely employed in internal medicine. (For its internal uses, see Acidum Benzoicum.) The compound tincture of benzoin is commonly employed, and its local application is of the greatest service in the treatment of acute coryza and in the early stage of inflammation of the pharynx when the throat feels harsh and dry. The inhalation of steam laden with the volatile portion of the preparation is also an excellent procedure in treating acute laryngitis. Anal fissure, cracked nipples, and superficial abrasions of the skin are also said to be benefited by its application. The compound tincture when mixed with water in the proportion of 1 part of the former to 7 parts of the latter has been largely employed by the laity as a cosmetic for the purpose of beautifying the complexion.

The dose of the drug is stated to be from 10 to 30 grains (0.60–2 Gm.) in emulsion or capsule.

BENZOSULPHINIDUM, *U. S.*—Benzosulphinide.

Glusidum, Br.; *Acide Anhydro-Orthosulfamide-Benzoique*, Fr. Cod.—*Gluside, Saccharin, Neosaccharin, Glucusimide, Benzoyl-sulphonic-imide, Orthosulphamide-benzoic anhydride, Anhydro-orthosulphamide-benzoic acid*, E.; *Saccharine, Sulfinide benzoique, Sucre de houille*, Fr.; *Saccharin, Benzoesäuresulfimid, Zuckerin, Toluolsüss, Saccharol, Sycose*, G.

The anhydride of orthosulphamide-benzoic acid.—U. S. A sweet imide derivable from toluene.—Br.

Formula, $C_6H_4\begin{matrix}SO_2\\CO\end{matrix}\!\!>\!NH$. Molecular weight, 181.77.

The name saccharin was first applied to this compound by C. Fahlberg, who had observed its sweet taste while working on the subject under the direction of Remsen at the Johns Hopkins University (see *Amer. Chem. Journ.*, 1879 and 1880). The name saccharin had been previously applied by Peligot to a crystalline, but not sweet, derivative-product of the sugar group.

Preparation.—Benzosulphinide is prepared commercially by different processes. Usually toluene is treated with concentrated sulphuric acid at 100° C. (212° F.), whereby ortho- and paratoluenesulphonic acids, $C_6H_4(CH_3)SO_3H$, are formed, which are first converted into calcium salts, and then, by means of sodium carbonate, into sodium salts. From these a mixture of ortho- and paratoluenesulphochlorides, $C_6H_4(CH_3)$-SO_2Cl, is obtained by action of phosphorus pentachloride; upon strongly cooling the mixture the para-modification crystallizes out, and is thus separated. Orthotoluenesulphamide, $C_6H_4(CH_3)SO_2NH_2$, is formed from the other isomeric chloride by means of dry ammonia gas. This sulphamide is next oxidized with potassium permanganate, converting it into potassium orthosulphamidebenzoate, the solution of which is freed from precipitated manganese dioxide and decomposed by means of an acid; instead of separating as free orthosulphamidebenzoic acid, the latter splits up into its anhydride and water. It is this anhydride which is officially recognized under the name benzosulphinide, but is commercially better known as saccharin or gluside.

Properties and Tests.—Saccharin occurs as a white, crystalline powder, nearly odorless, having an intensely sweet taste even in dilute solutions. It is soluble at 25° C. (77° F.) in 250 parts of water and in 25 parts of alcohol, and but slightly soluble in ether and chloroform; soluble in 24 parts of boiling water. (The Br. P. gives the solubility at 1 part in 400 parts of cold and 24 parts of boiling water, or 25 parts of cold 90 per cent. alcohol, whereas the Fr. Cod. gives it as 1 part in 335 of cold

or 28 parts of boiling water, or 30 parts of 95 per cent. alcohol). It is easily soluble in ammonia-water, in alkaline hydroxide solutions, and in a solution of sodium bicarbonate, with the evolution of carbon dioxide. Heated to between 219° and 220° C. (426.2° and 428° F.), saccharin melts and at higher temperature burns with an odor of oil of bitter almond, without leaving a weighable residue. If 0.2 Gm. of benzosulphinide be dissolved with agitation in 10 Cc. of pure sulphuric acid, and the solution kept at a temperature of from 48° to 50° C. (118.4°–122° F.), on a water-bath, it should not within 10 minutes show a brown color (absence of carbohydrates). If 0.2 Gm. of benzosulphinide be dissolved in 5 Cc. of potassium hydroxide test-solution, the solution should be clear, and not become colored, even on prolonged heating (absence of glucose). A similar solution mixed with 5 Cc. of alkaline cupric tartrate volumetric solution should not, on heating, deposit any red cuprous oxide (absence of glucose or milk sugar). If to a hot aqueous solution of benzosulphinide ferric chloride test-solution be added, drop by drop, no precipitation or violet color should appear (absence of benzoic or salicylic acids).—U. S. On evaporating gluside with excess of solution of potassium hydroxide, maintaining the residue in a state of semifusion for a few minutes, cooling, dissolving in water, faintly acidulating with hydrochloric acid, and adding a few drops of ferric chloride test-solution, a reddish-brown or purplish color is produced (Br.). Since parasulphamidebenzoic acid does not possess a sweet taste, and its presence in the official article would materially reduce the sweetening power of the latter, the Br. P. directs the following test for the presence of this contamination: A solution of 0.5 Gm. of gluside in 80 Cc. of warm water, set aside for 12 hours, deposits tabular crystals which melt between 218.8° and 220° C. (426° and 428° F.); and it should not, even when briskly shaken, deposit crystals melting at a higher temperature. Crystals of parasulphamidebenzoic acid melt between 280° and 283° C. (536° and 541.4° F.). When first introduced commercially, saccharin frequently contained 30 per cent. or more of this impurity. The sweet taste of saccharin is perceptible even in dilution of 1 to 100,000. Fused with sodium or potassium hydroxide it yields salicylic acid. When saccharin is fused with potassium nitrate and sodium carbonate, sodium sulphate is formed.

The presence of saccharin in food-products and mixtures may usually be determined by extracting the saccharin from an acidulated solution of the substance with ether, separating the ether, and subjecting the residue obtained by evaporation of the ethereal solution to the tests given above.

Action and Uses.—Saccharin is employed as a substitute for sugar to sweeten the food, drinks, or medicines of diabetic or gouty patients. Tablets containing ½ grain of saccharin combined with a small quantity of sodium bicarbonate are conveniently carried by diabetics to be used in coffee, etc. As the substance retards the action of all digestive ferments, it should be used with caution in those whose digestion is impaired.

Allied and Derivative Products.—Sodium Saccharin.—*Soluble Saccharin. Soluble Gluside. Crystallose.* $C_6H_4COSO_2N.Na + 2H_2O$.—This compound is prepared by neutralizing an aqueous solution of saccharin with sodium carbonate or bicarbonate and slowly crystallizing the solution. It occurs in colorless crystals, readily soluble in water, intensely sweet to the taste, and not discolored by concentrated sulphuric acid. It is much used in place of saccharin on account of its greater solubility.

Dulcin.—*Sucrol. Valzine. Paraphenetol carbamide.* $C_6H_4.OC_2H_5NH.CONH_2$.—Another synthetic sweet compound obtained when ammonia is allowed to act on a body produced by the reaction between 1 molecule of carbonyl chloride in benzene or toluene solution and 2 molecules of paraphenetidin. Dulcin occurs in colorless needles or scales, soluble in 80 parts of cold water, in 150 parts of boiling water, in 25 parts of alcohol, in 80 parts of 45 per cent. alcohol, and in 480 parts of glycerin. It melts at 173° C. (343.4° F.), leaves no residue after ignition, and is soluble in sulphuric acid without discoloration.

If 0.05 Gm. of dulcin be heated with 5 drops of concentrated sulphuric acid until vapors arise, then cooled, diluted with 10 Cc. of water, and ammonia-water carefully superimposed, a blue ring will appear at the point of contact of the acid and alkaline liquid. Dulcin, evaporated on the water-bath with either silver nitrate or mercuric chloride, produces a violet color soluble in alcohol to a wine-red solution (Hager). It does not yield sulphate on fusion with potassium nitrate and sodium carbonate (distinction from saccharin). Dulcin is used like saccharin.

BERBERIS, *U. S.*—Berberis; Barberry.

The dried rhizome and roots of *Berberis aquifolium* Pursh., or of other species of *Berberis* (Fam. *Berberidaceæ*).

Origin.—A genus (Fam. *Berberidaceæ*) of some 75 species, widely distributed through temperate regions, including tropical mountains. They are erect or prostrate shrubs or small trees, usually spiny and with spiny-toothed, coriaceous leaves, yellow flowers, and berry-like fruits somewhat resembling currants in appearance and in their strongly acid taste. These fruits have been used for preserves and as refrigerants, those of some Indian species being regularly in native commerce for the latter purpose. Both the bark and the wood are of a bright yellow color, and are permeated with the bitter alkaloids, the former more so. As drugs, the bark is most largely used, the roots next, the trunk-wood occasionally. The bark of the root is richer than that of the stem. The leaves also are used as an antiscorbutic. The well-known medicinal species form three groups, as follows, besides which some Andean species are similarly used:

1. BERBERIS VULGARIS L., the common European and West Asiatic barberry (*Sourberry* or *Sowberry, Wood-sour, Jaundice-berry, Barbaraune*, E.; *Berberitze, Saurach, Sauerdorn*, G.; *Berbéride, Épine-vinette, Vinettier*, Fr.; *Berberos*, Sp.), is a large scarlet-fruited shrub, cultivated and naturalized in some parts of North America.

FIG. 60.

Berberis: stem-bark, young and old (Nat.).

Description.—The root is thick, strongly branched, hard and tough; its wood porous, radiate, light-yellow. Its *bark* occurs in small, very thin, soft, and brittle fragments, which are easily separable into layers, externally yellowish-gray or light yellow-brown and short scaly, the inner, yellow surface smooth, the fracture deep-yellow, radiate, with the bast-fibers arranged tangentially. It has little odor but an intensely bitter taste, and tinges the saliva yellow. The stem-bark can be distinguished by its occurrence in strips or longer fragments, usually of a rather lighter yellow, and the outer surface ragged with more elongated scales or strips of partly detached cork.

Constituents.—The bark contains gum, fat, wax, resin, very little tannin, phytosterin ($C_{26}H_{44}O.H_2O$), and 4 alkaloids, 1 of which is yet unstudied. *Berberine* ($C_{20}H_{17}NO_4$), first found in Xanthoxylum, and called *xanthopicrit*, crystallizes in yellow bitter prisms or needles, and is soluble in alcohol and in 300 parts of water, insoluble in ether; its golden-yellow salts dissolve in water with difficulty. *Oxyacanthine* (berbine or vinetine, $C_{18}H_{19}NO_3$, and not the same as the alkaloid from *Cratægus Oxyacantha*) occurs in bitter white crystals, which are alkaline and turn yellow in sunlight. It dissolves in ether, 30 parts of alcohol, and with difficulty in water. *Berbamine* ($C_{18}H_{19}NO_3$) is crystalline and soluble in water, alcohol, and ether. The wood contains berberine and oxyacanthine.

The flowers and berries of this species (as of *B. aquifolium* L.) contain berberine, oxyacanthine, 3.5 to 4.7 per cent. of sugar, 6 to 6.6 per cent. of malic acid, and some volatile oil.

2. A group of semi-prostrate Rocky Mountain species classed by Nuttall as a separate genus, *Mahonia* (chiefly *B. aquifolium* Pursh), known as *Oregon grape-root, Rocky Mountain grape, Holly-leaved barberry*, or *California barberry*, and having a very high repute among miners and frontiersmen. The entire root is used. It closely resembles the last, but the bark is either nearly smooth or somewhat fissured, very little inclined to scale. The wood is also rather tougher than the last, and of a rather deeper yellow. The roots rarely exceed 2 inches in diameter, and are flexuous and somewhat knotty. The prostrate stem, or pseudorhizome, is frequently buried and rooting, and is collected with the root. The composition and properties of Oregon grape-root practically agree with those of *B. vulgaris*.

3. A Himalayan group, the species most used being *B. Asiatica* Roxb. (*Darhalad*, Hind.). Both the bark and the root are employed, and they are very similar in all respects to those of *B. vulgaris*. *B. aristata* DC. has been found to contain more than 2 per cent. of berberine.

Nearly 50 species are recorded as being similarly used.

Fig. 61.

Berberis aquifolium (¾ Nat.).

Pharmaceutical Preparation.—Fluidextract of Berberis, U. S.

Action and Uses.—Moderate doses of berberis act as a tonic, stimulant, and antiperiodic; larger amounts, as an active cathartic and hepatic stimulant. It is also said to be diuretic and antiscorbutic. Berberis has been given in atonic dyspepsia, diarrhœa, and dysentery, intermittent, remittent, and typhoid fevers, and in chronic enlargement of the spleen resulting from malarial infection. It has been suggested in the treatment of infantile and tubercular diarrhœa and in scorbutic and scrofulous conditions, but its employment has not been attended with any more success than that derived from the administration of other bitter tonics and purges.

The dose is stated to be from 5 to 12 grains (0.30–0.60 Gm.), in powder, pill, or capsule. The dose of the fluidextract is from 5 to 12 minims (0.30–0.60 Cc.), several times daily. An infusion, 2 drachms (8 Gm.) to 1 pint (480 Cc.), may be given in tablespoonful doses.

Berberis aquifolium has been employed as an antisyphilitic, antiperiodic, and tonic, and is said to have been successfully used in the treatment of inveterate cases of psoriasis and eczema and in chronic uterine diseases. It has also been suggested in atonic dyspepsia with constipation.

Berberidaceæ.—This family, of 8 genera and about 130 species, besides yielding the important drugs Podophyllum, Caulophyllum, and Berberis, elsewhere considered, contributes several minor drugs, the most important being *Jeffersonia*.

Jeffersonia (*Twin-leaf, Yellow root, Helmet pod, Ground-squirrel pea*), the rhizome and roots of *Jeffersonia diphylla* (L.) Pers. (*Podophyllum d.* L.; *J. binata* Bart.; *J. Bartonis* Mx.).—This is a low perennial herb, growing abundantly in rich forest-land between the Alleghenies and the Mississippi River, flowering in early spring. The leaves are radical, long-petioled, of 2 obliquely ovate leaflets. The scape is nearly a foot high, and terminates in a white flower, about 1 inch broad, of 4 fugacious sepals and 8 petals and stamens, followed by a many-seeded obovoid capsule. The rhizome somewhat resembles that of Caulophyllum, but is shorter. It is knotty, yellowish-brown, and matted with numerous long fibrous roots of similar color. It has little odor, but a bitter and acrid taste. Like its relatives, it contains berberine (but little) and a white alkaloid. It contains also an acrid glucoside of the nature of saponin, and perhaps another similar one resembling polygalic acid, resin, tannin, starch, and a little sugar. Its action and uses are very similar to those of Caulophyllum, or perhaps even more like those of Senega.

The leaves of *Epimedium alpinum* L. (*Bischofschmütze, Sockenblume*), of the Alps, are used as a diaphoretic, are credited with preventing conception, and are applied to swollen breasts.

The tuberous rhizome of *Leontice Leontopetalum* L., of the Mediterranean region, appears to have a composition similar to that of *Jeffersonia*. It is used as an antidote to opium- and snake-poisoning; so also is *Nandina domestica* Thunb., of Japan.

BETANAPHTHOL, *U. S.*—Betanaphthol.

Naphthol, Br.; *Naphtholum*, P. G.; *Naphtol*, U. S., 1890; *Naphthol β*, Fr. Cod.; *Naphtol, β-Naphthol, Beta-mono-hydroxy-naphthalene, Iso-naphthol*, E.; *Beta-Naphthol*, G.

Formula, $C_{10}H_7OH$. Molecular weight, 142.98.

A phenol occurring in coal-tar, but usually prepared artificially from naphthalene. It should be preserved in dark amber-colored, well-stoppered bottles.—U. S.

Naphthol was first prepared by Schäffer (1869) by fusing beta-naphthalene sulphonic acid with potassium hydroxide, and later (1876) by Liebermann by action of nitrous acid on beta-naphthylamine.

Preparation.—Concentrated sulphuric acid is allowed to act on naphthalene for several hours at a temperature of 200° C. (392° F), whereby β-naphthalene sulphonic acid is formed ($C_{10}H_7.HSO_3$); during the early stage of the process, and particularly at 80°–90° C. (176°–194° F.), much alpha acid is produced, but at a higher heat this is converted into the beta variety. The acid is next dissolved in water, saturated with milk of lime, and the resulting calcium salt separated by crystallization; this is redissolved in water and decomposed by sodium carbonate, yielding sodium-naphthalene-sulphonate, $C_{10}H_7SO_3Na$. The sodium-salt is next added to fused sodium hydroxide, and thus sodium-naphthol, $C_{10}H_7ONa$, and sodium sulphite, Na_2SO_3, are obtained; the former is treated with hydrochloric acid, yielding β-naphthol and sodium chloride. Betanaphthol thus obtained is purified by sublimation and final recrystallization from hot water or benzin (petroleum ether). Medicinal naphthol should be free from alpha-naphthol, with which the commercial varieties are frequently contaminated to the extent of 5 per cent. or more.

Properties and Tests.—Colorless or pale buff-colored, shining, crystalline laminæ, or a white or yellowish-white crystalline powder, having a faint phenol-like odor, and a sharp and pungent, but not persistent taste. Permanent in the air. Soluble at 25° C. (77° F.) in about 950 parts of water and in 0.61 part of alcohol (at 15° C. (59° F.) in 1000 parts of water or 0.75 part of alcohol, Br. and P. G.); in about 75 parts of boiling water, and very soluble in boiling alcohol. Also very soluble in ether, chloroform, or solutions of caustic alkalies. When heated betanaphthol sublimes easily. It is also volatilized with the vapors of alcohol or water. It melts at 122° C. (251.6° F.) and boils at 286° C. (546.8° F.). On ignition it leaves no residue. It is neutral to litmus-paper moistened with alcohol. A cold, saturated, aqueous solution of betanaphthol, when mixed with ammonia-water, exhibits a faint bluish fluorescence. Chlorine- or bromine-water, added to the aqueous solution, produces a white turbidity, which disappears on adding ammonia-water in excess. On adding about 0.1 Gm. of betanaphthol to a few Cc. of a concentrated, aqueous solution (1 in 4) of potassium hydroxide, then about 1 Cc. of chloroform, and gently warming, the aqueous layer will acquire a blue tint, changing after a while to green and brown. Ferric chloride test-solution colors an aqueous solution of betanaphthol greenish, and after some time causes the separation of white flakes, which turn brown upon the application of heat. On dissolving betanaphthol in 50 parts of ammonia-water, no residue should be left (absence of naphthalene), and the solution should not have a deeper tint than pale yellow (absence of other organic impurities). An aqueous solution of betanaphthol on the addition of chlorinated lime should show a pale-yellow color and not a dark violet (distinction from, and absence of, alphanaphthol). If a few drops of iodine test-solution be added to an aqueous solution of betanaphthol and followed by sodium hydroxide test-solution in excess, no color should appear (distinction from, and absence of, alphanaphthol, which produces an intensely violet color).—U. S. 0.1 Gm. of betanaphthol dissolved in 10 Cc. of boiling water, and treated with 10 drops of a 3 per cent. aqueous solution of ferric chloride, gives a white precipitate, becoming brown, but not violet (absence of alphanaphthol).—Br. Iodic acid substituted for the ferric chloride in the previous test gives similar color reactions. A cold saturated solution of aqueous betanaphthol gives a white turbidity with solution of chlorine, which, on the addition of excess of ammonia-water, gives place to a green or brown coloration (Br.). Betanaphthol containing as little as 1 per cent. of alphanaphthol gives a violet to violet-rose color when a saturated aqueous solution of the same, previously diluted with an equal volume of water, is treated with 3 drops of solution of sodium hypobromite.

Action and Uses.—Betanaphthol is employed both internally and externally as an antiseptic. It has been recommended internally as an antiseptic in the treatment of enteric fever, fetid diarrhœa, and gastric fermentation accompanied with flatulence. It may be locally applied in the form of an ointment containing from 10 to 15 per cent. of the drug in the treatment of scabies, psoriasis, pruritus, acne, and lupus. The internal dose is from 2 to 5 grains (0.12–0.30 Gm.), in capsule, several times daily.

Derivatives and Allied Compounds.—ALUMNOL, *Aluminum naphtholsulphonate.*—Introduced by Heinz and Liebrecht toward the close of the year 1892 as an astringent antiseptic. It is obtained by mutual decomposition between aluminum sulphate and barium naphtholsulphonate. An almost colorless non-hygroscopic powder readily soluble in cold water or glycerin ; it is less soluble in alcohol and insoluble in ether. The aqueous and alcoholic solutions show a blue fluorescence and have an acid reaction. A peculiar reaction of alumnol consists in the precipitation of solutions of albumen and gelatin, the precipitate being redissolved by an excess of the latter substance. A 40 per cent. solution prepared with hot water remains clear upon cooling ; an aqueous solution of alumnol is colored blue by ferric chloride.

ASAPROL, *Abrastol, Calcium beta-naphthol-alpha-monosulphonate.* $(C_{10}H_6.OH.SO_3)_2Ca + 3H_2O$.—This compound was introduced by Stackler and Duleif as an antiseptic in 1892. It is obtained by neutralizing the free acid with calcium carbonate, concentrating the solution and crystallizing. Asaprol occurs as a colorless neutral crystalline powder soluble in 1½ parts of water and 3 parts of alcohol. Its aqueous solution is colored blue by ferric chloride. It has been given internally in doses of from 15 to 60 grains (1 to 4 Gm.) a day.

BENZONAPHTHOL. *β-Naphthol benzoate, Benzoyl-naphthol. Benzoesäure-β-Naphthol-ester,* G. $C_6H_5CO_2.C_{10}H_7$.—Benzonaphthol is obtained by the action of benzoyl chloride on betanaphthol. The reaction begins at 125° C. (257° F.), and is completed in half an hour at 170° C. (408° F.). The product is washed several times with dilute solution of sodium hydroxide and recrystallized from hot alcohol. It occurs as a white crystalline powder melting at 107° C. (224.6° F.). It is tasteless, odorless, and insoluble in water and dilute sodium hydroxide solution, but soluble in alcohol, chloroform, and hot ether. It dissolves in concentrated sulphuric acid with a yellowish color, which, diluted with about 10 volumes of water and supersaturated with ammonia, develops a strong green fluorescence. Administered internally it splits up into β-naphthol and benzoic acid in the intestines. It is used more particularly as an intestinal antiseptic, and administered in doses of from 4 to 8 grains (0.25 to 0.50 Gm.) in capsules, or suspended in syrup and water.

BETOL OR BETANAPHTHOL SALICYLATE, *Naphthalol, Naphthosalol, Salinaphthol.* C_6H_4-$OHCO_2.C_{10}H_7$.—A crystalline compound analogous to salol and prepared in a manner identical with that employed for the latter substance, except that sodium-naphthol is used instead of sodium-phenol. In order to free the crude product from the accompanying sodium chloride and metaphosphate, it is well washed with water and then crystallized from its solution in alcohol. Pure betol occurs as a colorless lustrous crystalline powder, without odor and taste and melting at 95° C. (203° F.) ; it is insoluble in water or glycerin, difficultly soluble in turpentine and cold alcohol, but readily soluble in boiling alcohol, ether, benzene, and warm linseed oil. Betol is not affected in the cold by moderately strong acids or solutions of the caustic alkalies, but when heated with concentrated solution it is split up into salicylic acid and beta-naphthol. As in the case of salol, the same effect is produced by the alkaline pancreatic juice and other intestinal ferments, but gastric juice has no effect upon it. Betol is readily distinguished from salol by its much higher melting-point (salol melts at 43° C. (109.4° F.)), and by the production of a pure lemon-yellow colored solution with pure concentrated sulphuric acid, which a trace of nitric acid changes to olive brownish-green ; salol gives no such color reactions. Betol has been administered in cases of vesical catarrh and articular rheumatism in doses of 5 or 6 grains 4 times a day. Alphol is the corresponding salicylic ester of α-naphthol.

CAMPHORATED NAPHTHOL is a brownish transparent, syrupy liquid, obtained by mixing 1 part of beta-naphthol with 2 parts of camphor ; it has been used with success in the antiseptic treatment of boils, coryza, etc. The pain caused by painting the diseased parts with camphor-naphthol may be alleviated by the addition of cocaine.

DIIODO-BETA-NAPHTHOL or NAPHTHOL-ARISTOL. $C_{10}H_6I_2O_2$.—A greenish-yellow compound, odorless and tasteless, insoluble in water, sparingly soluble in alcohol, ether, or acetic acid, but freely soluble in chloroform ; when heated, it evolves violet fumes. It is made by mixing a solution of 2.4 parts each of iodine and potassium iodide with a solution of 11 parts of beta-naphthol and 4 parts of sodium carbonate, and then adding to the mixture a solution of sodium hypochlorite, which precipitates the new compound.

EPICARIN. *β-Oxynapthyl-o-Oxy-m-Toluylic Acid.* $(COOH)(OH)C_6H_3.CH_2.C_{10}H_6.OH$.—A parasiticide occurring commercially as a pure and as an impure variety, the latter used for veterinary purposes. Epicarin (pure) is prepared by recrystallizing "Epicarinum Veterinarium" from glacial acetic acid and drying the crystals at 120° C. (248° F.) or recrystal-

lizing them from alcohol. A colorless crystalline powder, difficultly soluble in chloroform, glacial acetic acid, benzene, oils, and hot water, but easily soluble in alcohol, acetone, and ether. It melts at 199° C. (390.2° F.). Its alcoholic solution is colored blue by ferric chloride. Concentrated sulphuric acid dissolves epicarin to a reddish-brown solution with a green fluorescence. The alkali salts of epicarin are soluble in water and alcohol. Epicarinum veterinarium occurs as a yellowish to reddish-colored crystalline powder. Epicarin is a non-poisonous antiseptic and parasiticide. Administered internally it is excreted mostly undecomposed. It has been found useful in the treatment of skin diseases, particularly scabies, herpes tonsurans, prurigo, and certain eczemas (*Apoth. Ztg.*, Feb. 21, 1900, 126). It is applied in the form of a 10 per cent. solution, or 10 to 20 per cent. ointment (*Dermatol. Zeitschrift*, 7, p. 1052).

HYDRONAPHTHOL.—A substance claimed to be a derivative of beta-naphthol, produced by acting upon the latter with reducing agents. It is stated to crystallize in silver-white laminæ, of a slight aromatic odor, and dissolving readily in alcohol, ether, chloroform, glycerin, benzene, and fixed oils, but requiring 1000 parts of water for solution. It melts at about 117° C. (242.6° F.). Commercial hydronaphthol is said to be merely impure beta-naphthol. Hydronaphthol has been suggested as a substitute for carbolic acid on account of its greater antiseptic power and because it is non-toxic and non-corrosive. It is not decomposed by organic matter, and is said to destroy the parasite causing *tinea tonsurans*.

LACTOL. *Lactonaphthol. β-Naphthol Lactate.* $CH_2CH.(OH)CO_2.C_{10}H_7$.—Phosphoric oxychloride is allowed to act at 120°–130° C. (248°–266° F.) upon molecular proportions of β-naphthol sodium and sodium lactate. The product is washed with water and crystallized from alcohol. Colorless crystals soluble in alcohol, but insoluble in water.

MICROCIDIN. *β-Naphthol-sodium.* $C_{10}H_7.ONa$.—Under this name a compound was recommended by Polaillon as an antiseptic, which is practically sodium-naphthol, and is obtained as a white powder by fusing beta-naphthol with half its weight of sodium hydroxide, and cooling. It is soluble in water (about 3 parts) and is non-caustic, and is used as a surgical antiseptic in aqueous solution containing from 0.3 to 0.5 per cent. of microcidin.

NAPHTHOL-BISMUTH.—*Betanaphthol-Bismuth, Orphol.* $C_{10}H_7O.Bi_2O_2(OH)$ or $(C_{10}H_7O)_3Bi + 3H_2O$(?).—The composition of this product is variously stated by different authors. It is said to be formed by the action of an alkaline solution of beta-naphthol on a solution of bismuth ternitrate in dilute glycerin, and occurs as a light-brown odorless powder, having but a slight, rather aromatic taste. It is insoluble in alcohol as well as water, and splits up in the intestines into naphthol and bismuth. Orphol is used as an intestinal astringent and antiseptic in the treatment of cholera infantum, gastro-intestinal catarrh, and typhoid fever in adult doses of 7.7 grains (0.5 Gm.), 5 or 6 times a day.

ALPHANAPHTHOL, isomeric with the beta-compound, may be obtained in the manner stated above; its chief use has been as a test for sugar in urine, as follows: If 1 drop of urine with 1 drop of a 10 per cent. solution of alpha-naphthol in chloroform is placed in a test-tube with 15 minims of water and concentrated sulphuric acid be then carefully poured in so that the chloroformic solution floats on it, a beautiful violet ring is formed at the line of contact of the two liquids if only $\frac{1}{30}$ per cent. of sugar be present (Molish and Luther). It resembles β-naphthol, but is more readily soluble in water, and according to M. Maximovitch (*Therap. Gaz.*, 24, 402) is three times more powerful as an antiseptic than beta-naphthol, and only one-third as poisonous. It melts at 95° C. (203° F.), and boils at 278° to 280° C. (532.4°–536° F.), and is distinguished from betanaphthol by the color reactions (see above). Alphanaphthol is official in the French Pharmacopœia.

BETULA.—Birch.

Birke, G.; *Bouleau*, Fr.; *Abedul*, Sp.

The bark and leaves of different species of *Betula* L. (Fam. *Betulaceæ*). There are about 35 species, aromatic trees, shrubs, or undershrubs, of the northern hemisphere. Their medicinal value depends partly upon natural constituents, partly upon those produced by destructive processes.

B. LENTA (*Sweet, Cherry, Spice*, or *Mahogany birch*, often incorrectly called *Black birch*, a name which properly belongs to *B. nigra* L.) is, medicinally, the most important species. It is abundant in the forests of northeastern North America, and southward in the mountains, preferring a sandy or gravelly loam. The young bark is of a beautiful dark glossy brown, with small light-colored spots. That of large trunks becomes nearly 12 Mm. (½ In.) thick, and roughly fissured, though the scales are thick and tenacious. Beneath the surface is a greenish or yellowish-green layer.

Constituents.—The important constituent is the glucoside *gaultherin*, which, upon decomposition, yields oil of birch, very similar to oil of wintergreen, and consisting of

almost pure methyl salicylate. There is also 3 or 4 per cent. of tannin. Gaultherin ($C_{14}H_{18}O_8+H_2O$) crystallizes in colorless needles, is soluble in alcohol, glacial acetic acid, and water, but not in chloroform, benzene, or acetone. It is very easily decomposed by water, even that in 94 per cent. alcohol being sufficient, doubtless through the action of an associated enzyme. It can be obtained unchanged by using a solution of lead acetate equal to 15 per cent. of the weight of the bark. It is easily decomposed by mineral acids or alkalies. The leaves contain the same constituents, and, like the bark, are largely used in domestic practice for their diuretic properties. The bark, as well as the oil, is largely employed as a flavoring agent.

Action and Uses.—Birch depends for its activity upon the volatile oil which it contains. This oil is nearly pure methyl salicylate, and is employed locally and internally for all conditions in which oil of wintergreen proves useful (see OLEUM GAULTHERIÆ). An infusion made with 1 ounce (30 Gm.) of the leaves and 1 pint (480 Cc.) of water, and also the saccharine juice which exudes from the tree when wounded, have been employed in the treatment of gouty and rheumatic conditions, in dropsy, and in diseases of the kidneys and bladder.

The dose of oil of birch is from 10 to 15 minims (0.60–1 Cc.), 3 times daily, usually administered in capsule. The infusion may be given in doses of from 1 to 2 fluidounces (30–60 Cc.).

Other Species.—*B. alba* L. (*B. verrucosa* Ehrh.), the European *White birch*, *Lady birch*, or *Ribbon tree*, is a native of northern Europe and Asia, represented in the United States by *B. populifolia* Marsh, long regarded as a variety of it. Its bark and leaves are aromatic, but the aroma is different from that of the last. The leaves are used similarly as a diuretic. Distilled with water, they yield ½ per cent. of a colorless, balsamic, and pungent volatile oil. Betuloresinic acid ($C_{36}H_{26}O_5$) exists as a whitish powder upon the young shoots and leaves. It is bitter, and dissolves in sulphuric acid with a red color. Upon dry distillation of the wood and bark, *birch-tar* or *Daggett* is obtained. This is the substance used in tanning Russian leather, and to which its agreeable odor is due. It yields the *oleum rusci* or *empyreumatic oil of birch*. The bark contains also a camphoraceous body, *betulin*, $C_{36}H_{60}O_3$, which forms light, flocculent, crystalline, tasteless masses, fusible at about 258° C. (496° F.), subliming when heated with care, and soluble in ether, volatile oils, hot alcohol, and alkalies. It forms a useful dyeing substance. On oxidation, one or more acids are obtained; and on dry distillation an oily body, which may be oleum rusci. Oleum rusci, or the empyreumatic oil obtained from this plant, has been used in the treatment of acne and other moist lesions of the skin, either in conjunction with an ointment-base or combined with ether and alcohol in the form of a lotion.

Quite a large number of other species of *Betula* are employed in domestic practice for their aromatic properties. The bark of *B. papyracea* Ait. is well known in the manufacture of Indian canoes.

BETULACEÆ.—This family, of 6 genera and about half a hundred species of shrubs and trees, yields a number of substances of pharmacological interest, outside of the genus *Betula*, just considered.

The ALDERS (*Alnus* Tournef) (*Erlenrinde*, *Erle*, *Eller*, G.; *Écorce d'aune*, *Aune*, Fr.; *Aile*, Sp.) comprise about 14 species, of which the barks of a number are used as mild astringents. They are largely used in Canada and elsewhere, in the powdered condition, for dusting upon chafed surfaces. The principal species employed are the *A. glutinosa* Gærtn. (*Betula alnus* L.), a tree of northern Europe and Asia, and *A. serrulata* Ait., a large shrub of North America. The European variety occurs in quills or curved pieces about 1.2 Mm. ($\frac{1}{20}$ In.) thick, smooth, of a brownish ash-gray color externally, the young bark with reddish-brown dots, the inner surface brownish-orange. It is almost odorless, and of an astringent and somewhat bitter taste; brittle, the fracture uneven but not splintery. The American variety, usually called *Black alder*, is of similar form, but blackish-gray with small suberous warts, the orange-brown inner surface more striate. The only active constituent of alder bark appears to be tannin, of which there is 4 or 5 per cent. The leaves and bark of A. *viridis* DC. are used as diaphoretics and as diuretics in dropsy, and a half dozen other species are employed locally as astringents and stomachics. The varieties of *Alnus* all possess astringent properties, and an infusion or decoction made with 1 ounce (30 Gm.) of either the leaves or bark and 1 pint (480 Cc.) of water has been given in doses of from ½ to 1 fluidounce (16–30 Cc.) in the treatment of diarrhœa and hæmaturia. The decoction may also be used as a mouth-wash or gargle in the treatment of stomatitis and pharyngitis. When injected into the vagina, it is said to cure leucorrhœa. *Alnus viridis* is said also to possess diuretic properties, and it may be efficacious in the treatment of dropsy.

The heart-wood and bark of *Ostrya Virginiana* (Mill.) Willd. (*Carpinus V.* Mill.; *O. Virginica* Willd.), the *Iron-wood*, *Hop hornbeam*, *Lever wood*, or *Black hazel*, of eastern North America, are bitter and employed as a substitute for quassia. Besides the bitter principle, there is about 5 per cent. of tannin. The wood is extremely hard and heavy. *Carpinus Cariolinana* Walt. (*C. Americana* Mx.), the *Iron-wood*, *American hornbeam*, *Blue*, *Water*, or *Horse beech*, of eastern North America, is often mistaken for Ostrya, but is not bitter. The

barks of both yield a yellow dyestuff. Iron-wood is said to be tonic, astringent, and antiperiodic. It may be employed in anorexia, diarrhœa, and intermittent fever. The dose in substance is from 30 to 60 grains (2–4 Cc.); of the fluidextract, from ½ to 1 fluidrachm (2–4 Cc.).

To this family also pertains the genus *Corylus* L., which yields the well-known filberts (*C. Avellana* L.) and hazelnuts, their kernels rich in bland fixed oil. The bark of *C. Avellana* yields a yellow dye. The bland oil obtained from the kernels of filberts may be employed for the same purposes as cotton-seed oil. The spicula covering the scaly involucre of *Corylus rostrata* is said to possess anthelmintic properties, which are probably due to its irritant effect.

BIGNONIACEÆ.—Calabash Family.

A large family, chiefly tropical, the plants mostly woody climbers. Aside from its highly ornamental character, it is of little importance, although a number of species are used in native medicine and have found a place in works on materia medica.

Catalpa (*Bean tree, Cigar tree, Candle tree*) is the bark or fruit of *Catalpa Catalpa* (L.) Karst. (*Bignonia C.* L.; *C. bignonioides* Walt.; *C. syringifolia* Sims), and of *C. speciosa* Warder (*C. cordifolia* Duham.), large trees of the eastern and southern United States. They bear large cordate leaves, of a peculiar satiny luster, ample panicles of 2-lipped, white flowers with purple and yellow spots, and 2-celled pods nearly a foot in length and half as thick as the finger, which hang upon the trees through most of the winter and spring. The seeds are numerous, thin, flat, and with a silky, membranaceous, fringed wing. The bark occurs mostly in quilled strips, about 6 Mm. (¼ In.) thick. It is gray-brown, glossy, and nearly smooth, except for its numerous small circular warts. The inner surface is smooth and white, becoming yellow or brownish with keeping. It has a slight peculiar odor and a very bitter taste. Both the bark and seeds contain tannin, resin, and sugar. E. A. Rau obtained from the bark a nauseous and bitter principle occurring in scales and soluble in ether, chloroform, and hot alcohol. F. K. Brown obtained 2 crystalline bodies from the seeds. Catalpa is rarely employed in medicine. The drug is said to possess emetic, vermifuge, and anodyne properties. A tincture made with 1 ounce (30 Gm.) of the seeds and pods in 1 pint (480 Cc.) of alcohol has been recommended in fluidrachm (4 Cc.) doses every 3 hours, in the treatment of asthma. The fresh juice obtained from the root is said to be valuable in treating chronic ophthalmia.

Catalpa speciosa is said to be a cardiac depressant, but its action has never been thoroughly studied.

Caroba, or Jacaranda, is the leaflets of *Jacaranda procera* (W.) Spreng. (*Bignonia p.* W.), *J. Caroba* (Vell.) DC. (*Bignonia C.* Vell.), and probably of other species of *Jacaranda*, these being tropical American trees. The leaflets pertain to a bipinnate leaf and vary greatly in size, being from 1 to 6 Cm. (⅖ to 2½ In.) long and about half as wide, elliptical to lance-oblong, oblique at the base, acute or obtusish, entire, coriaceous, glandular-hairy on both surfaces, and velvety along the veins underneath; nearly odorless, bitter, and astringent. They yield nearly 3 per cent. of the soft aromatic resin *carobone*, which is greenish and slightly acrid, about half as much of a balsamic substance having the odor of cumarin, an amaroid, tannin, tasteless resin, several acids, and the crystalline inodorous substance *carobin*. Caroba is said to be alterative, diaphoretic, and diuretic. An infusion or decoction is employed in Brazil in the treatment of syphilis, strumous conditions, and chronic rheumatism.

Oroxylum (*Arlu, Sona, Nasona*) is the bark and seeds of *Oroxylum Indicum* (Blume) Vent. (*Calosanthes I.* Blume), a small and curious tree of India, where the drug is largely used as an astringent, tonic, and alterative. Holmes describes the bark as "about 2 lines thick, the external portion consisting of a soft, spongy cork of a fawn or light-brown color, easily indented by the nail and striated longitudinally. The internal layer or liber is fibrous and of a greenish-yellow tint. It is nearly odorless and has an acrid and faintly bitter taste." The important constituents are fat, wax, pectin, sugar, an astringent principle, an acrid principle, and *oroxylin*, a peculiar crystalline principle, insoluble in water but readily soluble in alcohol and ether, and, even in very minute amount, yielding a cherry-red color with alkali hydroxides, quickly changing to brick-red and olive-green. The seeds, under the name of *damree*, have been found very efficacious as an application to a destructive cattle disease practically identical with *tinea tonsurans*.

Some 50 other species of the family have been recorded as of medicinal use, and the indications are that some of them, used in asthma and as hypnotics, will be found to possess valuable properties. The ripe fruit of *Kigelia pinnata* DC. contains a bitter principle and is used in tropical Africa as a purgative. While green, it is used as an alterative. The pulp of the fruit of the calabash (various species of *Crescentia*) is used in pulmonary diseases. The various parts of *Stereospermum chelonioides* (L.) DC. have many medicinal uses. *Newbouldia lævis* Seem., of West Africa, is an antidysenteric; the root of *Pajanelia multijuga* DC., of Malabar, is used to relieve headache and in the treatment of catarrh. A number of species of *Bignonia* and *Tecoma* are used in tropical America as sarsaparilla substitutes or as diuretics, and *T. radicans* (L.) Juss., of the southern United States, is a fish poison.

BISMUTHI CITRAS, *U. S.*—Bismuth Citrate.

Citrate de bismuth, Fr.; *Wismutcitrat, Citronensaures Wismutoxyd*, G.

Formula, $BiC_6H_5O_7$. Molecular weight, 394.52.

It should yield not less than 58 per cent. nor more than 60 per cent. of pure bismuth oxide.—U. S.

The salt is directed to be prepared by boiling together for about 15 minutes 100 parts of bismuth subnitrate, 75 parts of citric acid, and 400 parts of water. The reaction is over when some of the sediment yields a clear solution with ammonia water. 5000 parts of distilled water are then added, and the suspended matter is allowed to settle and finally washed by decantation and on the filter until the wash-water is tasteless, after which it is dried at a gentle heat.—U. S. This is the process of R. Rother, proposed in 1876, and consists in the decomposition of the subnitrate by citric acid at the boiling temperature. Yield, about 135 parts.

Properties.—Bismuth citrate is a white, amorphous or microcrystalline powder, odorless and tasteless, permanent in the air, insoluble in water or alcohol, but soluble in ammonia water and in solutions of alkali citrates. It chars when strongly heated and leaves a residue soluble in nitric acid. When dropped into water, this solution gives a white turbidity of bismuth subnitrate. Hydrogen sulphide precipitates black bismuth sulphide from its solution in ammonia; and when the filtrate is mixed with an equal volume of concentrated sulphuric acid and cooled, no dark color should appear around a crystal of ferrous sulphate dropped into the liquid (absence of nitrate). If 1 Gm. of the salt be thoroughly ignited in a porcelain crucible, and, after cooling, be dissolved by cautiously warming with nitric acid, evaporated to dryness, and again ignited, the residue of bismuth oxide should weigh not less than 0.58 Gm. nor more than 0.6 Gm. (U. S.). Tests for arsenic and heavy metals, chlorides, and sulphates are the same as under the following compound.

Action and Uses.—Bismuth citrate is not employed in medicine, but was made official for the purpose of preparing *Bismuthi et Ammonii Citras.*

BISMUTHI ET AMMONII CITRAS, *U. S.*—Bismuth and Ammonium Citrate.

Bismuthi ammonio-citras. Bismuthum citricum ammoniatum.—Citrate de bismuth ammoniacal, Fr.; *Wismutammoncitrat, Citronensaures Wismutammonium*, G.

It should yield not less than 48 per cent. of pure bismuth oxide.—U. S.

Preparation.—Bismuth citrate, 100 Gm.; ammonia-water, distilled water, each a sufficient quantity. Mix the bismuth citrate with 200 Cc. of distilled water to a smooth paste, heat the mixture on a water-bath, and gradually add ammonia-water until the salt is dissolved and the liquid has a neutral or only faintly alkaline reaction. Then filter the solution. Evaporate it to a syrupy consistence, and spread it on plates of glass, so that on drying the salt may be obtained in scales. Keep the product in small, well-stoppered vials, protected from light.—U. S.

Rother (1876) states that dry bismuth citrate yields with ammonia water a syrupy liquid and a hard white mass, the latter being unaffected by excess of ammonia, but dissolving on the application of a gentle heat; this solution crystallizes on cooling, and the crystals, after being dried on a water-bath, are again soluble in water, and may be regarded as a compound of triammonium citrate with bismuth hydroxide, having the formula $(NH_4)_3C_6H_5O_7Bi(OH)_3$. Since the Pharmacopœia makes no provision for supplying the ammonia lost during the concentration of the liquid, the salt will have a more or less variable composition, probably approaching that determined by N. Gray Bartlett (1865) for a salt prepared by a similar process, namely, $BiC_6H_5O_7NH_4OH.2H_2O$ (molecular weight, 468.33). The yield by the official process is about 120 Gm.

Properties.—Bismuth and ammonium citrate occurs in small, shining, pearly or translucent scales, odorless, having a slightly acidulous and metallic taste, and becoming opaque on exposure to the air, very soluble in water, and but very sparingly soluble in alcohol. When strongly heated, the salt fuses, then chars, and leaves a more or less blackened residue having a yellow surface and soluble in warm nitric acid. This solution, when dropped into water, occasions a white turbidity. The aqueous solution of the salt is neutral or faintly alkaline to litmus-paper. When boiled with potassium or sodium hydroxide test-solution, it evolves the vapor of ammonia, and when treated with hydrogen

sulphide it yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with lime-water, produces a white precipitate (citrate). If another portion of the filtrate be mixed with an equal volume of concentrated sulphuric acid and cooled, no brown or brownish-black zone should appear around a crystal of ferrous sulphate dropped into the liquid (absence of nitrate). If 3 Gm. of the salt be ignited and the residue, dissolved in the least amount of nitric acid, be poured into 100 Cc. of water, and the filtrate, separated from the precipitated subnitrate, be evaporated to 30 Cc., refiltered and divided into 5 Cc. portions, these should respond to the tests for purity given under BISMUTHI SUBCARBONAS. —U. S. No evidence of arsenic should be obtained when 3 Gm. of the salt are ignited and tested by the Bettendorf method, as given under ARSENI TRIOXIDUM.

The dry salt slowly loses ammonia on keeping, thereby becoming partly insoluble in water; the cautious addition of a few drops of ammonia water to such a turbid mixture will then usually make a perfect solution.

Action and Uses.—This salt differs from the insoluble salts of bismuth in being more astringent and irritating. It may be employed in internal medicine in the treatment of serous diarrhœa resulting from a relaxed condition of the mucous membrane of the intestinal tract; but it should never be given when acute inflammation or irritation is present. The dose is from 2 to 4 grains (0.12–0.25 Gm.), best administered in solution.

BISMUTHI OXIDUM, *Br.*—Bismuth Oxide.

Bismuthum oxydatum.—*Oxyde de bismuth*, Fr.; *Wismutoxyd*, G.

Formula, Bi_2O_3. Molecular weight, 461.44.

Preparation.—The present British Pharmacopœia gives no details of preparation. Former directions were as follows: Take of bismuth subnitrate, 1 pound; solution of soda, 4 pints. Mix and boil for 5 minutes; then, having allowed the mixture to cool and the oxide to subside, decant the supernatant liquid, wash the precipitate thoroughly with distilled water, and finally dry the oxide by the heat of a water-bath. In this process the bismuth subnitrate is decomposed by the soda, sodium nitrate and white bismuth hydroxide being formed, the former of which remains dissolved in the water: $2(BiONO_3.H_2O) + 2NaOH$ yields $2Bi(OH)_3$ or $Bi_2O_3.3H_2O + 2NaNO_3$. On drying the precipitate without heat, it loses water and leaves *bismuthyl hydroxide*, BiO.OH, but at the temperature of boiling water the anhydrous oxide is left.

Properties.—Bismuth oxide forms a dull-yellow more or less crystalline powder, which dissolves in mineral acids without effervescence, and these solutions are colorless and yield black precipitates with hydrogen sulphide, and white ones with alkalies, alkali carbonates, and much water, the precipitates being insoluble in an excess of the precipitants. When heated to incipient redness, the oxide is not diminished in weight. At a higher temperature it fuses to a brown mass, which becomes yellow again on cooling. The oxides of lead and silver are likely to be present as impurities, and are detected by dissolving in nitric acid and testing as described under Bismuthi Subnitras. Each Gm. should yield 1.1 Gm. of bismuth sulphide (Br.).

Action and Uses.—Oxide of bismuth may be employed for the same purposes as the subnitrate of bismuth. Its dose is from 5 to 20 grains (0.3–1.3 Gm.).

BISMUTHI SUBCARBONAS, *U. S.*—Bismuth Subcarbonate.

Bismuthi carbonas, Br.; *Bismuthum subcarbonicum.*—*Carbonate of bismuth, Bismuthyl carbonate, Bismuth oxycarbonate*, E.; *Sous-carbonate de bismuth*, Fr.; *Wismutsubcarbonat, Basisches kohlensaures Wismutoxyd*, G.

Formula, $(Bi_2O_2CO_3)_2.H_2O$, Br.; $(BiO)_2CO_3.H_2O$(?). Molecular weight, 522.99(?).

It should yield not less than 90 per cent. of pure bismuth oxide.—U. S.

Preparation.—Neither the United States nor the British Pharmacopœia gives an official process. The British states that it may be prepared by the action of ammonium carbonate on bismuth nitrate. The details of such a process may be stated as follows: Mix 4 fluidounces of nitric acid with 3 fluidounces of distilled water, and add 2 ounces of purified bismuth in small pieces in successive portions. After the action is

over, heat for 10 minutes at nearly the boiling-point, let settle, and decant from any insoluble matter present. Evaporate the solution to 2 fluidounces and add it a little at a time to a cold filtered solution of 6 ounces of ammonium carbonate in 2 pints of distilled water, with constant stirring. Filter, and wash the precipitate until the washings are tasteless. Dry at a temperature not above 65.6° C. (150° F.) (Br. 1885).

Most metallic bismuth contains some arsenic, which is also oxidized by the nitric acid, so that bismuth arsenate is found in the solution, unless purified bismuth has been used. In order to remove nearly the whole of the arsenic, the nitric acid solution may be diluted with sufficient distilled water until it remains faintly milky after stirring; on being set aside for a day most of the arsenate will be found deposited as a white crystalline precipitate. The clear solution, still retaining a small proportion of arsenic, may be almost completely deprived of it by pouring it into an excess of ammonia water, whereby soluble ammonium nitrate and arsenate are formed, while bismuth hydroxide is precipitated; this may then be converted into subcarbonate by dissolving in sufficient nitric acid, pouring the liquid slowly and with constant stirring into a solution of sodium carbonate, draining the precipitate upon a strainer, and washing it with distilled water. This process was originally proposed by Dr. Squibb, and adopted in the U. S. P. 1870. In following this process it is important that the dilution with water should be carried sufficiently far to cause a turbidity which does not disappear completely on stirring; this solution should be set aside for a sufficient length of time, as indicated; the acid solutions should be added slowly and with continual stirring to the alkaline solutions, in order to insure the complete decomposition of the acid salt; and the washing should not be continued for too long a time, in order to avoid gradual decomposition of the subcarbonate into hydrate. If the final precipitation be effected at a boiling temperature, an anhydrous subcarbonate would be precipitated. The final reaction may be explained by the equation: $2Bi(NO_3)_3 + 3Na_2CO_3 + H_2O = (BiO)_2CO_3.H_2O + 6NaNO_3 + 2CO_2$, showing that carbon dioxide is given off.

Properties.—Bismuth subcarbonate is a white or pale yellowish-white powder of somewhat varying chemical composition, odorless and tasteless, and permanent in the air. It is insoluble in water or alcohol, but completely soluble in nitric or hydrochloric acid with copious effervescence. When heated to redness, the salt loses water and carbon dioxide, and should leave not less than 90 per cent. of a yellow residue which is soluble in nitric or hydrochloric acid and blackened by hydrogen sulphide.—U. S.

Tests.—If 3 Gm. of the salt be dissolved in just a sufficient quantity (about 4 Cc.) of warm nitric acid, and the solution poured into 100 Cc. of water, a white precipitate is produced (subnitrate). After filtering, and evaporating the filtrate on a water-bath to 30 Cc., again filtering, and dividing this filtrate into portions of 5 Cc., these should respond to the following tests: On mixing one portion with an equal volume of diluted sulphuric acid it should not become cloudy (absence of lead). If another portion be precipitated with a slight excess of ammonia water, the supernatant liquid should not exhibit a bluish tint (absence of copper). Other portions should not be affected by barium nitrate test-solution (sulphate), nor yield, with hydrochloric acid, a precipitate which is insoluble in a slight excess of the latter (silver). If 1 Gm. of the salt be boiled with 10 Cc. of a mixture of equal parts of acetic acid and water, and the cold filtrate freed from bismuth by hydrogen sulphide, the new filtrate should leave no fixed residue on evaporation (absence of alkalies and alkaline earths). On boiling 1 Gm. of the salt with 10 Cc. of sodium hydroxide test-solution, it should not evolve the odor of ammonia. If 0.05 Gm. of the salt be shaken with 5 Cc. of a mixture of equal parts of water and ferrous sulphate test-solution, and then cautiously poured upon 5 Cc. of sulphuric acid (free from nitrous compounds), no brownish-red zone should form at the line of contact (limit of subnitrate). If 0.1 Cc. of tenth-normal silver nitrate be added to 0.3 Gm. of the salt dissolved in 10 Cc. of diluted nitric acid, and the precipitate, if any, filtered off, the clear filtrate should not be affected by addition of more of the silver solution (limit of chloride). 2 Gm. of the salt should not respond to the Bettendorf test for arsenic (see under ARSENI TRIOXIDUM).—U. S.

The Br. P. requires that 1 Gm. dissolved in hydrochloric acid and diluted with water acidified with the same acid, when treated with hydrogen sulphide, should yield a precipitate weighing, after rapidly washing and drying at 100° C. (212° F.), 0.99 Gm., corresponding to 89.7 per cent. of Bi_2O_3. F. A. Upsher Smith (*Pharm. Jour.*, Dec. 15, 1900) thinks this method troublesome and liable to give erroneous results in inexperi-

enced hands, and he therefore prefers the determination of bismuth as oxide as being simpler and more reliable.

Action and Uses.—The subcarbonate of bismuth may be used interchangeably with the subnitrate of bismuth, as its effects are practically identical.

BISMUTHI SUBGALLAS, *U. S.*—Bismuth Subgallate.

Bismutum subgallicum, P. G.; *Bismuthyl gallate*, E.; *Sous-gallate de bismuth*, Fr.; *Basisches Wismutgallat (gallsaures Wismutoxyd)*, *Wismutsubgallat*, G.

Formula, $C_6H_2(OH)_3COOBi(OH)_2$(?). Molecular weight, 408.43(?).

It should yield not less than 52 per cent. nor more than 57 per cent. of pure bismuth oxide.—U. S.

Preparation.—Dissolve 15 parts of normal bismuth nitrate in 30 parts of glacial acetic acid, add 200 to 250 parts of water, and filter. To the filtrate add with constant stirring a warm solution of 5 parts of gallic acid in 200 or 250 parts of water. The resulting precipitate is separated by decantation and washed until free from nitric acid; it is then dried at 100° C. (212° F.).

Properties.—It is known commercially as *dermatol*. Bismuth subgallate occurs as an impalpable, lemon-yellow, odorless powder, permanent in the air, and insoluble in all ordinary solvents. It may be sterilized at 100° C. (212° F.) and is indifferent to light. The composition of the commercial samples varies slightly. L. F. Kebler found 52.73 per cent. and 54.63 per cent. as the lowest and highest content, respectively, of Bi_2O_3 in 10 samples examined (*Am. Jour. Pharm.*, 1899). The per cent. of Bi_2O_3 according to the formula above is 54.33. The compound was prepared and described by H. Bley, in 1841, but was lost sight of until 1891, when B. Fischer again prepared and described it. It is readily soluble, with decomposition, when heated with hydrochloric, nitric, and sulphuric acids, but is insoluble in very dilute solutions of these acids. It is easily dissolved by the alkalies, forming a clear yellow solution, which rapidly changes to a deep red. It loses from 5 to 7 per cent. of water at 120° C. (248° F.), and on heating to redness it first chars and finally leaves a yellow residue, which is soluble in hydrochloric and nitric acids and is blackened by ammonium sulphide solution (bismuth). When 0.1 Gm. of the salt is thoroughly shaken with an excess of hydrogen sulphide solution, the black precipitate of bismuth sulphide filtered off, and the filtrate boiled to expel the hydrogen sulphide and cooled, it will assume a blue-black coloration upon adding 1 drop of ferric chloride test-solution (gallic acid).

Tests.—If 1 Gm. be incinerated and the yellow residue dissolved in nitric acid, cautiously evaporated to dryness and heated again, not less than 0.52 Gm. nor more than 0.57 Gm. of Bi_2O_3 should remain. The residue resulting from 2 Gm. of the salt, as just described, should not respond to the Bettendorf test for arsenic (given under ARSENI TRIOXIDUM). If 3 Gm. of the salt be ignited, cooled, cautiously dissolved in nitric acid by warming, evaporated and again ignited, then redissolved in about 4 Cc. of nitric acid and further treated as described under BISMUTHI ET AMMONII CITRAS, 5-Cc. portions of the resulting liquid should respond to the tests for purity given under BISMUTHI SUBCARBONAS. The filtrate from 0.5 Gm. of the salt, well shaken with 5 Cc. of alcohol, should not turn moistened blue litmus-paper red (absence of free gallic acid). If 0.5 Gm. of the salt be well mixed with 5 Cc. of diluted sulphuric acid and 5 Cc. of ferrous sulphate test-solution, and the mixture carefully poured upon 5 Cc. of sulphuric acid (free from nitrous compounds), no brown ring should appear after standing for 10 minutes (limit of nitrate).—U. S.

1 Gm. dissolved in 5 Cc. of sodium hydroxide solution and warmed with a mixture of 0.5 Gm. each of zinc filings and powdered iron, should give no ammonia (absence of nitrate). A mixture of 1 Gm. of the subgallate and 3 Cc. of stannous chloride solution should not assume a dark color in one hour (absence of arsenic). The filtrate from 1 Gm. of the subgallate shaken with 10 Cc. of alcohol should not leave a weighable residue when evaporated.—P. G.

Action and Uses.—The subgallate of bismuth, largely used under the trade name of dermatol, has been introduced as an absorbent and astringent dressing-powder in various eruptions and irritations of the skin accompanied by excessive secretion. By its physiological properties it aids in drying up secretion, and by its astringent effect constricts the bloodvessels in the inflamed part. It has also been used internally in the treatment of diarrhœa and dysentery, in the dose of from 5 to 20 grains (0.3–1.3 Gm.).

BISMUTHI SUBNITRAS, *U. S.*, *Br.*—Bismuth Subnitrate.

Bismutum subnitricum, P. G.; *Bismuthum hydrico-nitricum*, *Magisterium bismuthi.*—*Bismuthyl nitrate*, E.; *Sous-azotate* (*Sous-nitrate*) *de bismuth*, Fr.; *Basisches Wismutnitrat* (*salpetersaures Wismutoxyd*), *Wismutsubnitrat*, G.

Formula, $BiONO_3HO_2$, Br. Molecular weight, 302.23.

It should yield not less than 80 per cent. of pure bismuth oxide.—U. S.

Preparation.—No method is given in the present United States and British Pharmacopœias.

In the method of the German Pharmacopœia, 1 part of bismuth is dissolved in 5 parts of nitric acid, specific gravity 1.2, previously heated to 75°–90° C. (167°–194° F.). After standing several days the solution is decanted and evaporated to crystallization. 1 part of the crystals is then rubbed uniformly with 4 parts of water and poured while stirring into 21 parts of boiling water. The precipitate is collected, drained, and washed with a volume of cold water equal to the filtrate, and then dried at 30° C. (86° F.). In this process the arsenic is gotten rid of as bismuth arsenate by allowing the first solution to subside for some days, and finally crystallizing the bismuth ternitrate, which salt is afterward decomposed by boiling water.

A former method of the Br. was as follows: Mix 4 fluidounces of nitric acid with 3 ounces of distilled water; dissolve in this 2 ounces of purified bismuth in small pieces. After solution heat for 10 minutes nearly to the boiling-point and decant from any sediment. Evaporate the solution to 2 fluidounces and pour it into ½ gallon of distilled water, let settle, decant, add ½ gallon of distilled water, stir the precipitate well, and after 2 hours decant the liquid, collect and dry the precipitate at a temperature not above 150° C. (302° F.).

By dissolving the metal in nitric acid the latter is partly decomposed, nitric oxide being evolved and water generated, while the bismuth dissolves, forming normal bismuth nitrate; thus, $Bi_2 + 8HNO_3 = 2Bi(NO_3)_3 + 2NO + 4H_2O$. Other metals likely to be present are dissolved with the formation of nitrates, except arsenic, which is oxidized to arsenic acid. The bismuth having been previously purified, the solution practically should contain only bismuth nitrate. The latter requires now to be converted into the subnitrate, which is accomplished by water. The most uniform results are obtained by adding the acid solution to a definite quantity of cold water; the decomposition taking place may be explained by the following equation: $6Bi(NO_3)_3 + 10H_2O = 5BiONO_3H_2O + Bi(NO_3)_3 + 10HNO_3$. The nitric acid which is liberated will retain a portion of normal bismuth nitrate in solution. Ditte ascertained that water containing in each liter 83 Gm. of $N_2O_5 = 96.83$ Gm. of HNO_3, will dissolve both normal and basic nitrate, forming with the latter the normal salt, so that no decomposition will take place on further addition of the acid liquid; but if the precipitate is left for too long a time in contact with the acid mother-liquor, an oxynitrate of the formula $4BiONO_3.Bi(OH)_3.3H_2O$ is gradually formed; by precipitating the solution with water at about 50° C. (122° F.) an oxynitrate is obtained having the composition $5BiONO_3.Bi(OH)_3.3H_2O$; and by washing the official or the above compounds for some time with water they are decomposed into still more basic salts of the formulas $3BiONO_3.Bi(OH)_3.3H_2O$ and $3BiONO_3.2Bi(OH)_3.H_2O$. It is obvious from the foregoing that even with the most careful manipulation the product obtained is not likely to be of a definite composition, but to consist of a mixture of the above two salts or of intermediate basic salts.

The physical character of the subnitrate is influenced by the temperature of precipitation. From cold solutions the precipitate is comparatively light and bulky; at 80° C. (176° F.), the precipitate formed is heavier and scanty, and more so at 100° C. (212° F.). F. A. Upsher Smith (*Pharm. Jour.*, 1900) has given a full account of the various methods of analysis and varying physical appearances of bismuth subnitrate.

Properties.—Bismuth subnitrate is a heavy white powder in minute crystalline scales and of a somewhat satiny appearance. It is not altered on exposure to air or light, is inodorous, has a faintly acid taste, and when moistened on litmus-paper has a slight but decided acid reaction. It is insoluble in water and alcohol, but dissolves completely and without effervescence in mineral acids. When heated to 120° C. (248° F.) it loses not over 3 per cent. of moisture, and at a red heat it gives off yellowish-red vapors, and leaves not less than 80 per cent. of a yellow residue, which is soluble in nitric or hydrochloric acid, and is blackened by hydrogen sulphide.—U. S. The formula given above requires 76.34 per cent. of Bi_2O_3. This difference may be due to loss of water by

drying at too high a temperature, but is usually owing to changes in its composition occurring during its preparation under the circumstances described above. The loss by ignition of these non-official oxynitrates ranges between 16 and 20 per cent.

Tests.—On dissolving 3 Gm. of the salt in 3 Cc. of warm nitric acid no effervescence should occur (absence of carbonate) and no residue should be left (absence of insoluble foreign salts). If this solution be poured into 100 Cc. of water, a white precipitate is produced, and, after filtering, evaporating the filtrate on a water-bath to 30 Cc., again filtering, and dividing the filtrate into portions of 5 Cc. each, these should respond to the tests of purity described under Bismuth Subcarbonas. When further tested as there described, the salt should be found free from alkalies and alkaline earths, and should give no reaction for ammonia. If 2 Gm. of the salt be heated in a porcelain crucible until nitrous vapors cease to be evolved, the residue, when cold, should not respond to the Bettendorf test for arsenic given under ARSENI TRIOXIDUM.—U. S.

Action and Uses.—Bismuth subnitrate is employed locally as a dusting-powder, mixed with powdered starch, in intertrigo and other irritative conditions of the skin. It has even been employed as a dusting-powder in the treatment of ulcers and burns, but has largely gone out of use for this purpose. Internally bismuth subnitrate is a valuable drug in that it exercises a sedative and astringent influence upon inflamed mucous membranes, and therefore is valuable in the treatment of acute gastric catarrh, acute gastro-enteritis, and in serous diarrhœa. It is also valuable for the purpose of checking vomiting depending upon acute gastric catarrh or gastric ulcer. Its use is contraindicated in diarrhœa associated with the passage of much mucus, unless a purge like castor oil or magnesium sulphate is previously administered, as it tends to cause retention of this secretion and thereby aggravates the condition. As a rule in the treatment of serous diarrhœa sufficiently large doses of bismuth subnitrate are not given. Doses varying from 20 to 60 grains (1.3–4 Gm.), every few hours, should be employed to get the full effect of the drug.

The administration of bismuth not infrequently gives a garlic-like odor to the breath, which is supposed to be due to contamination of the bismuth by tellurium. Bismuth also causes any coating of the tongue to become black in color, and the stools also become black. As bismuth is insoluble, it is administered best in powdered form or in capsules or cachets. As it is almost tasteless, the powder is not objectionable. If extremely large doses of bismuth are taken for a long period of time, it is capable of producing chronic poisoning, consisting in the formation of ulceration and sloughing of the intestinal mucosa. Bismuth has been employed in many other affections than those named, but possesses little value except in the diseases mentioned.

The dose is from 10 grains to 1 drachm (0.60–4 Gm.).

BISMUTHI SUBSALICYLAS, *U. S.*—Bismuth Subsalicylate.

Bismuthi salicylas, Br.; *Bismutum subsalicylicum*, P. G.; *Bismuth salicylate, Bismuthyl salicylate, Bismuth oxysalicylate*, E.; *Sous-salicylate de bismuth*, Fr.; *Basisches Wismutsalicylat (salicylsaures Wismutoxyd), Wismutsubsalicylat*, G.

Formula, $C_6H_4(OH)COO.BiO$, Br. Molecular weight, 358.79.

It should yield not less than 62 nor more than 64 per cent. of pure bismuth oxide.—U. S.

Preparation.—The U. S. P. and P. G. give no method of preparation, and the British gives only an outline, stating that the compound may be prepared by the interaction of sodium salicylate and bismuth nitrate. It may be prepared by Duyk's process; thus, 500 Gm. of pure bismuth subnitrate are digested with 1000 Cc. of distilled water for 2 days, with frequent stirring, in a warm place; 50 Cc. of strong ammonia water are now added, the liquid drawn off, and the residue, Bi_2O_3, washed until free from nitric acid; the moist oxide is transferred to a wide-mouthed bottle, a little distilled water and 125 Gm. of salicylic acid are added, and the mixture digested at ordinary room temperature, with frequent stirring, for at least 48 hours. The bismuth subsalicylate is then washed with small quantities of cold water until all free acid has been removed, and the product finally dried at a low temperature and kept in a dark place. As thus prepared, the salt occurs as a cream-colored, odorless, and tasteless amorphous powder, free from uncombined salicylic acid and from bismuth subnitrate.

Fischer and Grützner (1894) found that commercial bismuth subsalicylate is not

constant in composition, and proposed a method of preparation which they claim gives a constant basic compound. Bismuth nitrate crystals are dissolved in 4 parts of dilute acetic acid, the solution is diluted with 40 times its weight of water, and ammonia-water added to precipitate bismuth hydroxide, which is washed and digested on a water-bath with the molecular proportion of salicylic acid. The mass of bismuth subsalicylate is poured on a filter, washed, and dried.

Paul Thibault (*Bull. Soc. Chim.*, 1901) describes a new crystallized bismuth salicylate, with the composition $(C_7H_6O_3)_2Bi_2O_3$. He attempted to get a pure compound by the various methods proposed, but failed. The process by which he obtained the above compound consists in digesting salicylic acid with bismuth oxide obtained in the usual way by precipitation from the nitrate by caustic soda and heating. Thibault's salt is described as a dirty, rose-colored crystalline powder, stable up to 140° C. (284° F.), which parts with the whole of its Bi_2O_3 with alkalies, in contrast to other salts of bismuth which are soluble in alkalies.

Properties.—It is a white, or nearly white, amorphous or crystalline powder, odorless, tasteless, and permanent in the air. It is almost insoluble in cold water, but prolonged boiling with water gives rise to a more basic salt, while a portion of the salicylic acid passes into solution. Treatment with alcohol or ether dissolves salicylic acid with decomposition of the salt. It is partly soluble with decomposition in hydrochloric and nitric acids, forming a white flocculent precipitate of salicylic acid. Heated to 120° C. (248° F.) the salt should not lose more than 1 per cent. of water, and at a red heat it at first chars and finally leaves a yellow residue (oxide), which is soluble in hydrochloric or nitric acid and is blackened by ammonium sulphide solution. The salt when agitated with a solution of 5 drops of ferric chloride test-solution in 10 Cc. of water produces a deep violet-blue color (salicylate). If 1 Gm. of the salt be thoroughly shaken with 10 Cc. of diluted hydrochloric acid and filtered, the residue, after washing and drying, should conform to the reactions and tests given under ACIDUM SALICYLICUM. Upon pouring the filtrate into an excess of water, a heavy white precipitate of basic bismuth chloride should be obtained.—U. S.

Tests.—If 1 Gm. of the salt be shaken with 5 Cc. of chloroform, and the liquid filtered into 5 Cc. of water containing 3 drops of ferric chloride test-solution, no violet zone should form within 5 minutes at the line of contact of the two liquids (absence of free salicylic acid). The Br. P. and P. G. have the following tests for free salicylic acid: If 0.5 Gm. of the salt be shaken with 5 Cc. of water, the filtrate should not redden blue litmus-paper at once (P. G.); the filtrate, after shaking the salt with 90 per cent. alcohol, should not give a purple color with ferric chloride solution. If 3 Gm. of the salt be ignited in a porcelain crucible, and when cold dissolved by cautious addition of nitric acid and warming, and the solution when concentrated to 4 Cc. be further treated as described under BISMUTHI ET AMMONII CITRAS, 5-Cc. portions of the resulting liquid should respond to the tests for purity described under BISMUTHI SUBCARBONAS. If 0.2 Gm. of the salt be triturated with 0.3 Gm. of sodium salicylate and 5 Cc. of distilled water, and carefully poured, without mixing, over 5 Cc. of sulphuric acid (free from nitric acid), no pink to brownish-red zone should form immediately (limit of nitrates). 1 Gm. of the salt dissolved in 5 Cc. of sodium hydroxide solution and warmed with a mixture of 0.5 Gm. each of zinc filings and powdered iron should give no ammonia (absence of nitrate, P. G.). The copper test for nitric acid should give only the faintest evidence of nitrate (Br.). If 1 Gm. of the salt dried at 120° C. (248° F.) be thoroughly ignited in a porcelain crucible, and treated further as described under BISMUTHI CITRAS, it should leave a residue of not less than 0.62 Gm. nor more than 0.64 Gm. of bismuth oxide. 1 Gm. should yield 0.7 Gm. of bismuth sulphide, or 62 to 64 per cent. (63 per cent., P. G.) of Bi_2O_3 (Br.). The residue of oxide, obtained by ignition of 2 Gm. of the salt and further treatment as described above, should not respond to the Bettendorf test for arsenic given under ARSENI TRIOXIDUM.

Action and Uses.—Bismuth subsalicylate has been largely employed as a substitute for the older bismuth preparations in conditions of diarrhœa associated with fermentation in the gastro-intestinal tract. By many practitioners it is considered a valuable intestinal antiseptic in typhoid fever and in infantile diarrhœa. It is a mistake to suppose that it in any way shortens the course of enteric fever, but it often does control diarrhœa. Its increased antiseptic power depends upon the salicylic acid which is combined with it.

The dose is from 2 to 20 grains (0.12–1.3 Gm.), according to the age of the patient.

BISMUTHUM.—Bismuth.

Wismuth, Wismut, G.; *Bismuth,* Fr.; *Bismutte,* It.; *Bismut,* Sp.

Symbol, Bi. Valence, in all bismuth salts, 3; in a few compounds, 5. Molecular weight, 206.9.

The supply of bismuth is chiefly derived from mines in Saxony, where it exists in the metallic state associated with cobalt, nickel, and silver ores. It is likewise found oxidized as *bismuth ochre,* in combination with sulphur and with tellurium, and in gold ores. Deposits of bismuth ore have been discovered in Hungary, France, Cornwall, and other parts of Europe, in Texas, California, Mexico, Bolivia, and other parts of America, and in Australia. Bismuth appears to have been first recognized as a distinct metal by Basilius Valentinus in the fifteenth century, but was afterward frequently confounded with antimony, tin, and zinc, until Pott (1739), and afterward Bergmann, Davy, and others, proved its distinct properties. The metal is extracted by a simple process of smelting, advantage being taken of its low melting-point, and run into hot iron receiving-pots, where it congeals. The bismuth sulphide requires to be roasted; it is thus converted into oxide, which is reduced to the metallic state by being heated with charcoal. The crude metal thus obtained contains variable quantities of arsenic, copper, iron, silver, gold, antimony, lead, nickel, cobalt, selenium, and tellurium.

Purified Bismuth.—Crude bismuth may be purified by careful fusion with a little niter, or, better, with 7 per cent. of potassium cyanide mixed with 2 per cent. of sulphur, or with sodium carbonate to which a little potassium chlorate has been added. Very pure bismuth can be obtained by heating insoluble bismuth oxalate or by boiling an alkaline glycerin solution of a bismuth salt with sugar, washing the precipitated bismuth with 1 per cent. sulphuric acid, and fusing.

Properties.—Bismuth is a brilliant grayish-white metal with a distinct roseate tinge and a crystalline lamellate texture. When fused bismuth is cooled until a crust has formed, and the liquid portion is then poured out, the crucible will be found lined with rhombohedral crystals resembling cubes. Its specific gravity is 9.83, which is diminished by high pressure. It fuses at 264° C. (507.2° F.), and when congealing expands considerably, like water under similar circumstances, the density of the liquid metal being more than 3 per cent. greater than that of solid bismuth. It boils at about 1600° C. (2912° F.), and may be distilled in a current of hydrogen. It is superficially tarnished at the ordinary temperature by exposure to the air, but at a red heat decomposes the vapor of water and burns in the air with a bluish flame to brown oxide, becoming yellow on cooling. It has the peculiar property of lowering the fusing-point of metals; an alloy of 2 parts of bismuth and 1 part each of lead and tin fuses at 93.75° C. (200.75° F.). It is but slightly attacked by boiling hydrochloric or dilute sulphuric acid; but nitric acid dissolves it readily, the solution on concentrating yielding crystals of bismuth nitrate (see Bismuthi Subnitras); the mother-liquor or the original solution in nitric acid, suitably diluted with water and separated from the white precipitate of subnitrate, should not yield a white precipitate with sulphuric acid (lead), or a blue one with potassium ferrocyanide (iron), or with the same reagent a reddish-brown (copper). The presence of arsenic is ascertained by adding sulphuric acid to the solution, evaporating it to complete dryness, and applying Marsh's or Fleitmann's test (see pages 247 and 249). Silver, which is occasionally present, will be indicated by the white precipitate which takes place in the nitric acid solution, previously diluted with water as much as possible, on the addition of hydrochloric acid. The fetid breath following the administration of bismuth preparations has been attributed by C. Ekin (1876) to the presence of tellurium; but from observations made by Squibb (1882) this appears to be doubtful, or at least not the sole cause.

The *salts of bismuth* are colorless, except those formed with a colored acidulous radical. The nitrate, sulphate, and chloride dissolve in a small quantity of acidulated water, but are decomposed by a large quantity of water, with the formation of insoluble basic salts. The solutions of bismuth salts yield with hydrogen sulphide a black precipitate insoluble in ammonium sulphide, with alkalies a white precipitate insoluble in an excess, and with zinc, cadmium, or copper a dark-gray spongy mass consisting of metallic bismuth. The solutions give with potassium iodide a yellowish-brown precipitate, becoming red on the addition of water; this coloring being so intense that a minute quantity

of bismuth may be detected in lead if the acetate is precipitated by an excess of potassium iodide and the mixture heated to boiling; on cooling, the golden-yellow color of the lead iodide will be tinged crimson, orange, or brown, according to the proportion of bismuth present (Field and Abel, 1877).

BISMUTH COMPOUNDS.

Bismutal.—*Bismuthol.*—A mixture of bismuth-sodium phosphate and sodium salicylate.

Bismutan.—*Isutan.*—A yellow powder, insoluble in water, consisting of bismuth tannate and resorcin.

Bismuthi Albuminas. *Bismuthum Albuminatum.*—*Bismuth albuminate*, E.; *Wismutalbuminat*, G.—A compound of Bi_2O_3 with egg-albumen, of uncertain composition. It is prepared by adding a solution of 75 parts of dried egg-albumen to 25 parts of bismuth and ammonium citrate dissolved in the least quantity of water, and drying at a low temperature. It is a grayish-white powder, of slightly acid reaction, forming usually a cloudy solution in water due to some insoluble albumen. The commercial article contains 10–12 per cent. of bismuth.

Bismuthi Benzoas. *Bismuthum Benzoicum.*—*Bismuth benzoate*, E.; *Benzoate basique de Bismuth*, Fr. Cod.; *Wismutbenzoat, Benzoësaures Wismut*, G. $C_6H_5CO_2BiO$ (?).—Prepared by heating on a water-bath a mixture of bismuth hydroxide and benzoic acid in water. A white, amorphous, odorless, tasteless powder, insoluble in water. Acids precipitate benzoic acid from it. Ferric chloride produces a tawny color, due to ferric benzoate. It leaves on incineration 65–70 per cent. of Bi_2O_3. It was first proposed by M. P. Vigier as a substitute for bismuth salicylate. It has been recommended as a substitute for iodoform.

Bismuthi Beta-naphtolas.—*Bismuth beta-naphtolate, Orphol.* $Bi_2O_2(OH).(C_{10}H_7O)$.—Formed by the action of an alkaline solution of beta-naphtol on bismuth trinitrate in solution in dilute glycerin or an acid. A brown, odorless, tasteless, neutral powder, insoluble in water and alcohol. Acids precipitate beta-naphtol. Internal antiseptic and substitute for iodoform.

Bismuthi Boras.—*Bismuth borate.* $BiBO_3$ (?).—Made by fusing boric acid with bismuth trinitrate. A yellowish-white insoluble powder, used as an intestinal antiseptic, like the subnitrate.

Bismuthi Borophenas.—*Bismuth borophenate, Markasol.*—A slightly astringent absorbent powder, recommended as a substitute for iodoform. It is free from odor.

Bismuthi Cerium-salicylas.—*Bismuth-cerium salicylate.*—An insoluble pink powder, used in diseases of gastric and intestinal mucous membranes.

Bismuthi Chrysophanas.—*Bismuth chrysophanate, Dermol.*—A yellowish-brown powder, said to have the composition $Bi(C_{15}H_9O_4)_3.Bi_2O_3$. According to E. Merck, it is a mixture of impure chrysarobin and bismuth hydroxide.

Bismuthi Dithiosalicylas.—*Bismuth dithiosalicylate, Thioform.* Probable composition, $[S\text{–}C_6H_3(OH)CO_2BiO]_2 + Bi_2O_3 + 2H_2O$.—Obtained by digesting sodium dithiosalicylate with bismuth trinitrate in the presence of caustic soda. A yellowish-brown, odorless powder, insoluble in water. Antiseptic, in place of iodoform. Internally for gastric and intestinal catarrh.

Bismuthi Lactas.—*Bismuth lactate.*—This is prepared by boiling 10 parts of bismuth subnitrate with an excess of caustic soda, washing the oxide well with water, and while still moist mixing it with 9 parts of lactic acid; the mixture is digested, and dried on a water-bath.

Bismuthi Loretinas.—*Bismuth loretinate or Iodo-oxyquinoline-sulphonate.*—Obtained by the action of bismuth trinitrate, dissolved with the aid of glacial acetic acid, on an aqueous solution of sodium loretinate. A yellow powder, insoluble in water. Internally in cases of diarrhœa of phthisis, externally as dusting-powder and as lanolin ointment.

Bismuthi Metacresolas.—*Bismuth metacresolate.*—A grayish-white powder, odorless and tasteless, similar in all respects to the phenolate, insoluble in water and alcohol. Used internally as an antiseptic, externally as a substitute for iodoform.

Bismuthi Methylenum-digallas.—*Bismuth methylene-digallate, Bismal.*—Obtained by digesting 4 molecules of methylene-digallic acid (a condensation-product between formaldehyde and gallic acid) with 3 molecules of bismuth hydroxide. A bluish-gray powder, soluble with yellow color in alkalies, from which it is reprecipitated by acids.

Bismuthi Oleas.—*Bismuth oleate.* $Bi(C_{17}H_{33}CO_2)_3$.—Formed by action of sodium oleate on bismuth trinitrate. An insoluble powder, with emollient and astringent properties.

Bismuthi Oxybromidum seu Subbromidum.—*Bismuth oxybromide.* BiOBr.—A yellow powder used in nervous dyspepsia.

Bismuthi Oxychloridum seu Subchloridum.—*Bismuth oxychloride or subchloride, Bismuthyl chloride*, E.; *Oxychlorure de bismuth*, Fr.; *Wismutoxychlorid*, G. BiOCl.—This is prepared by slowly pouring a solution of bismuth in nitric acid into a solution of sodium chloride. It is a white powder, known as *pearl white*, and in France, like bismuth subnitrate, as *blanc de fard*. When heated in closed vessels, it turns yellow and melts without decomposition, but on being heated in the air chlorine is given off and bismuth oxide is left. The salt is insoluble in water, but readily soluble in acids. It has occasionally been sold as oxide of bismuth.

Bismuthi Oxyiodidum seu Subiodidum.—*Bismuth oxyiodide or subiodide, Bismuthyl iodide*, E.; *Oxyiodure de bismuth*, Fr.; *Wismutoxyiodid*, G. BiOI.—It may be prepared by pouring with constant stirring a solution of 95.4 Gm. of crystallized bismuth nitrate in 120 Cc. of glacial acetic acid into 2 liters of water containing 33.2 Gm. of potassium iodide and 50 Gm.

of sodium acetate. Wash by decantation, filter, wash, and dry at 100° C. (212° F.). It is a vivid red, heavy powder with an odor of iodine, insoluble in water, alcohol, and chloroform. Heated in a dry tube, it gives off iodine, leaving a residue of Bi_2O_3. Acids and alkalies decompose it. It is used as a dusting-powder or as an ointment.

Bismuthi Oxyiodo-methylgallolum. — *Bismuth oxyiodo-methyl-gallol. Iodo-gallicin.* $C_6H_2(OH)_2\begin{cases}OBi(OH)I\\CO_2CH_3\end{cases}$.—Prepared, like airol, by the action of bismuth oxyiodide on gallicin (methylgallate). It is a dark-gray powder, insoluble in the ordinary solvents. It contains 23.6 per cent. of iodine and 38.4 per cent. of bismuth. Substitute for iodoform.

Bismuthi Oxyiodo-pyrogallas.—*Bismuth oxyiodo-pyrogallate.* $C_6H_2(OH)_2.O.Bi(OH)I$.—Prepared by digesting bismuth oxyiodide with pyrogallic acid, or precipitating a solution of potassium iodide and pyrogallic acid with bismuth nitrate in acetic acid. A fine yellowish-red powder, stable in light and air. Powerful antiseptic and substitute for iodoform.

Bismuthi Oxyiodo-subgallas seu Gallas.—*Bismuth oxyiodosubgallate*, E.; *Wismutoxyiodidgallat*, G.; *Airol.* $C_6H_2(OH)_3CO_2Bi(OH)I$.—It is prepared by heating 35 parts of freshly precipitated bismuth oxyiodide in 50 parts of water with 18.8 parts of gallic acid on a water-bath until the oxyiodide has been converted into a grayish-green powder. Also by warming equivalent quantities of bismuth subgallate and hydriodic acid in water. It is a voluminous, odorless, tasteless powder, insoluble in water or alcohol. It is soluble in acids and alkalies with change of color. It gradually changes to a red powder in moist air. It contains 24.4 per cent. of iodine. It is used as a substitute for iodoform as a dusting-powder, or in 10 per cent. ointment free from water.

Bismuthi Peptonas.—*Bismuth peptonate.*—This is prepared from 20 parts of bismuth and ammonium citrate and 80 parts of dried peptone, exactly as described under Bismuth Albuminate. A grayish-brown, slightly acid powder, insoluble in alcohol. The commercial article contains 7–8 per cent. of bismuth.

Bismuthi Phenolas seu Carbolas.—*Bismuth phenolate or carbolate*, E.; *Phenol-Wismut*, G. $C_6H_5O.Bi(OH)_2$.—Prepared by action of bismuth nitrate in solution on sodium phenolate. A grayish-white, neutral, nearly odorless and tasteless powder, insoluble in water and alcohol. Decomposed by hydrochloric acid into bismuth chloride and phenol. Intestinal antiseptic and substitute for iodoform.

Bismuthi Phosphas Solubilis.—*Bismuth phosphate, soluble.*—Obtained by fusing bismuth oxide, phosphoric oxide, and sodium phosphate together. A white crystalline powder, soluble in 2 parts of water. Concentrated solutions are unstable, dilute ones become cloudy only after 2 or 3 days. The solutions are alkaline, have a bitter, salty taste, and are rendered cloudy by acids or alkalies, or by boiling.

Bismuthi Pyrogallas. — *Bismuth pyrogallate*, E.; *Pyrogallol-Wismut*, G. *Helcosol.* $[C_6H_3(OH)_2O]_2Bi.OH$.—A yellow, odorless, tasteless powder, insoluble in water. It is soluble in alkalies, turning brown by absorption of oxygen. It contains 48 per cent. of Bi_2O_3.

Bismuthi Resorcinas.—*Bismuth resorcinate*, E.; *Resorcin-Wismut*, G. $[(C_6H_4O_2)_3Bi_2]_3 + Bi_2O_3$.—A yellowish-brown powder containing about 40 per cent. of Bi_2O_3.

Bismuthi Sulphis.—*Bismuth sulphite.*—Obtained by precipitating a solution of bismuth nitrate with sodium sulphite. Antiseptic and antifermentative.

Bismuthi Tannas.—*Bismuth tannate*, E.; *Tannate de bismuth*, Fr.; *Wismuttannat*, G.—12 parts of bismuth subnitrate are converted to the hydroxide by shaking repeatedly with 10 parts of ammonia water (0.96) in 15 parts of water. After 4 or 5 hours, filter, wash well, and while yet moist mix the oxide carefully with 15 parts of tannic acid in 15 parts of water, evaporate, and dry thoroughly on a water-bath and rub to a powder. It forms a light-yellow powder which is insoluble in water and alcohol, and is entirely tasteless. When thoroughly dried, its composition represents 53 per cent. of bismuth oxide and 47 per cent. of tannin.

Bismuthi Tribrom-phenolas seu Carbolas.—*Bismuth tribrom-phenolate or carbolate*, E.; *Tribromphenol-Wismut*, G.; *Xeroform.* $Bi_2O_2.(OH).(OC_6H_2Br_3)$.—Yellowish, neutral, odorless, tasteless powder, insoluble in water and alcohol, containing about 57 per cent. of bismuth oxide. Acids act on it as in the case of the phenolate.

Bismuthi Valerianas.—*Bismuth valerianate*, E.; *Valérianate de bismuth*, Fr.; *Wismutvalerianat*, G.—A solution of bismuth nitrate in the smallest quantity of nitric acid, previously diluted with half its weight of water, is precipitated by a rather concentrated solution of sodium valerianate; the precipitate is washed with water, to which some valerianic acid has been added, until the washings, on evaporation, leave no residue, and afterward dried. Or 50 parts of bismuth subnitrate are digested for 4 hours with 150 parts of ammonia diluted with an equal weight of water; the sediment, consisting of bismuth hydroxide, is well washed with water, drained, transferred to a mortar, and well triturated with 15 parts of concentrated valerianic acid, 30 parts of alcohol being gradually added during the trituration. It is afterward collected upon a filter and dried at the ordinary temperature. Prepared by either process, it is a white amorphous powder having a decided odor of valerianic acid, insoluble in water and alcohol, soluble in nitric and in sulphuric acid; the latter solution does not acquire a black color on the addition of ferrous sulphate (absence of nitrate). Other impurities may be detected by the same tests as given under Bismuth Subnitrate.

BOLDUS.—Boldo.

Boldo, G., Fr.

The dried leaves of *Boldu Boldus* (Molino) Lyons (*Peumus Boldus* Molino.—Fam. *Monimiaceæ*).

FIG 62.

Boldo leaf (Nat.).

Origin.—A large, stout, dense, aromatic, evergreen, diœcious shrub of the Chilian coast-region, the bark used for tanning and the wood esteemed for charcoal-making.

Description.—Very shortly and stoutly petioled, the blade 4 to 6 Cm. (1½ to 2½ In.) long and two-thirds as broad, ovate-oval, subcordate at the base, blunt or slightly notched at the summit, entire and revolute at the margin, thick and coriaceous, yellowish or pale-green or sometimes brownish, harshly papillose above, hairy and paler underneath, where the reticulate venation is very prominent; aromatic, the odor somewhat terebinthinate; taste aromatic and pungent.

Constituents.—The leaves contain tannin, aromatic resinous compounds, 2 per cent. of yellow volatile oil, of a specific gravity of 0.915 to 0.945, and lævogyrate, colored hyacinth-red by sulphuric acid, violet by nitric acid, red by potassium hydroxide, and decolorized by hydrochloric acid; it is freely soluble in alcohol, commences to boil at 185° C. (365° F.), and contains no aldehyde. There is also 0.1 per cent. of *boldine*, a bitter alkaloid scarcely soluble in water, but readily soluble in alcohol, ether, and chloroform.

Pharmaceutical Preparation.—FLUIDEXTRACT OF BOLDO, N. F.

Action and Uses.—Boldus acts as a nervous sedative and hypnotic, and has been employed as a tonic and hepatic stimulant. It has been suggested as a remedy for atonic dyspepsia, chronic rheumatism, torpid liver, and chronic hepatitis. The volatile oil contained in the leaves is eliminated by the kidneys, and is said to be efficacious in the treatment of catarrhal conditions of the genito-urinary tract. Boldine has been used as a local anæsthetic, and it is claimed to be the equal of cocaine. Its administration in mania and excitement of the brain has been productive of quiet sleep, and it is thought by some to be superior to opium, in that it produces no untoward after-effects.

Tincture of boldus (1 in 5) is given in doses of from 5 to 20 minims (0.3–1.30 Cc.); the fluidextract, from 1 to 4 minims (0.05–0.25 Cc.); and boldine, in doses of 3 grains (0.20 Gm.), preferably in capsule.

Monimiaceæ.—This family, to which Boldo pertains, comprises some 23 genera, and about 150 species of trees and shrubs, mostly of tropical America. They are characterized generally by terebinthinate, aromatic, and resinous constituents, in many cases associated with bitter substances. *Atherosperma moschatum* R. Br., the *Sassafras tree* of New Holland, yields a bark much like that of sassafras and similarly employed, containing saffrol and the alkaloid *atherospermine*, which is a white amorphous powder readily soluble in alcohol and chloroform, but dissolving sparingly in ether; its colorless solution in sulphuric acid becomes green with potassium chromate (Zeyer, 1861). *Daphnandra micrantha* Benth. and *Atherosperma repandulum* F. Müll. (*Daphnandra r.* F. Müll.) appear to act similarly. The bark of the latter is very poisonous. It yields an alkaloid, which is to some extent antagonistic to strychnine. Locally applied, it paralyzes all muscles. It retards putrefaction and deodorizes putrid meat; checks the growth of *Torula cerevisiæ* and kills some water-plants. *Doryphora sassafras* Endl., of the same region, also contains saffrol and is similarly used, as are the leaves and fruit of *Laurelia aromatica* Juss., of Chile, and several species of *Siparuna* Aubl., of tropical America. In Australia, the leaves of *Piptocalyx Morrei* Oliv. are used for their bitter tonic effects, and the same is true of the barks of *Tambourissa quadrifida* Sonn. (*Mithridatea q.* W.; *Ambora Tambourissa* Lam.) and *T. religiosa* DC.

Calycanthus.—Several species of the genus *Butneria* Duham. (*Calycanthus* L.—Fam. *Calycanthaceæ*) possess properties, and apparently constituents, similar to those of the *Monimiaceæ*. These are the deliciously fragrant shrubs cultivated under the names *Sweet-scented shrub*, *Strawberry shrub*, *Bubby bush*, *Carolina* or *Florida allspice*, etc. The root, leaves, and bark of *B. fertilis* (Walt.) Kearney (*Calycanthus f.* Walt.; *C. lævigatus* W.; *C. glaucus* W.), of the southeastern United States, are a much used antiperiodic. Its seeds contain the very peculiar alkaloid *calycanthine*, occurring in crystals of phenomenal hardness. *Chimonanthus præcox* (L.) Lindl., *Calycanthus p.* L., the *La-mei* or *Hwang-mei-hwa* of Japan, has a pungently aromatic bark.

BORAGINACEÆ.—The Borage Family.

Few families of plants have contributed more herbs to professional and domestic medicine than this. Of its 1200 species, in nearly 100 genera, more than 100 are recorded as having been in medicinal use, yet not one is now official or has a place in any list of important therapeutic agents. This disrepute is perhaps not wholly deserved, since recent examinations have shown some of them to contain, though in very small amount, active and even poisonous constituents. Mucilage abounds in nearly all. Those which are called for with sufficient frequency to be of interest to the pharmacist are here considered.

Borago (*Borage, Burrage,* or *Star-flower,* E.; *Borasch* or *Boretsch,* G.; *Bourrache,* Fr.; *Borraja,* Sp.) is the annual herb *Borago officinalis* L., indigenous to the Levant, wild in various parts of Europe, and extensively cultivated for ornament and as a salad and medicinal plant (Fig. 65). It is from a fleshy, white root, 30 to 60 Cm. (1 to 2 Ft.) high, erect-branching, hispid-hairy throughout; leaves alternate, oval to obovate, the lower petioled, the upper becoming sessile, entire or somewhat wavy, thickish; calyx and corolla 5-parted, the latter rotate, blue to reddish, the throat closed by 5 emarginate appendages and bearing 5 stamens; fruit of 4 brownish-black, ovate, roughish nutlets which are excavated at the base to sit upon the broad gynobase; odor and taste slight, peculiar, mucilaginous. It contains mucilage, a little resin, and a large percentage of salts, among them 2 or 3 per cent. of potassium nitrate. Borage is slightly diuretic, diaphoretic, and demulcent. An infusion made with 3 drachms (12 Gm.) of the drug and 1 pint (480 Cc.) of boiling water, may be employed in the treatment of febrile conditions, catarrhal affections, and rheumatic complaints. The expressed juice from the leaves and stem may be used in doses of from 1 to 3 fluidounces (30–90 Cc.).

Cynoglossum officinale L. (*Hound's tongue, Dog's tongue* or *Dog-bur, Sheep-lice, Gypsy-flower, Tory-weed,* E.; *Hundszunge, Venusfinger,* G.; *Cynoglosse, Langue de Chien,* Fr.), *Anchusa officinalis* L. (*Ox-tongue, Bugloss, Garden alkanet,* E.; *Ochsenzungenkraut,* G.; *Buglosse,* Fr.), and *Echium vulgare* L. (*Viper's bugloss, Blue-thistle, -weed, -stem,* or *-devils,* E.; *Natterkopf,* G.; *Viperine,* Fr.), form a group containing the alkaloid *cynoglossine,* which forms double compounds with mercuric and platinic chlorides, and acts like curare, and the glucoside *consoldin,* which acts in some ways like an alkaloid and paralyzes the central motor system. It splits up into glucose and the alkaloid consolicine, which is also found free in the plants. The latter acts like the glucoside, but is 3 times as active. Both the *Anchusa* and the *Echium* named, are stout, erect, very hispid-hairy perennial herbs, 1 to 2 feet high, with blue flowers, changing to a purplish-red, those of the former in a cyme, of the latter in axillary clusters, forming an interrupted raceme. The roots are long, thick, and fleshy, brown externally, white internally. The leaves are petioled below, sessile above, those of the Anchusa lanceolate or lance-ovate, of Echium lance-linear to linear. Echium is abundantly naturalized in waste fields of this country. Hound's tongue has been recommended as a sedative and demulcent in the treatment of bronchial and pulmonary affections. It is said to be of value also in dysentery. The fresh leaves are used locally as a remedy for superficial burns and abraded surfaces. The extract when injected into the circulation is said to paralyze the motor nerves without diminishing sensation or muscular irritability.

Fig. 63.

Borage (½ Nat.).

Alkanna (*Alkanet, Orcanette, Spanish bugloss*) is the root of *Alkanna tinctoria* (L.) Tausch (*Anchusa t.* L.), a perennial herb, native of southeastern Europe and adjacent Asia. It is used rather in dyeing than in medicine, containing 5 to 6 per cent. of the red coloring-matter alkannin (*anchusic acid*). The root as found in the market is 30 Cm. (1 Ft.) or less in length, and about as thick as the finger, several-headed, and often crowned by whitish leaf-remnants. The soft bark easily separates into 3 layers, has a dark-purplish color like the medullary rays, and covers a harder, yellowish, irregularly twisted, and spongy wood. Syrian alkanna is the root of *Macrotomia cephalotes* DC., grown in Asia Minor. It is very similar to the ordinary, and is said to contain more than twice as much of the same or a very similar red coloring-matter, which is also found in many other plants of this family. The root of *Onosma echioides* Lam. is used similarly. Alkanet is no longer employed in medicine, but its coloring-matter is used for coloring various pharmaceutical preparations.

Pulmonaria (*Lungwort, Jerusalem* or *Bedlam cowslip, Spotted comfrey, Beggar's basket,* E.; *Lungenkraut,* G.; *Pulmonaire officinale,* Fr.) is the perennial rough-hairy herb of *Pulmonaria officinalis* L., its root-leaves ovate-cordate and petioled, the upper becoming smaller and at length sessile, frequently marked with white spots and bluish-purple nodding flowers. Quite similar is the American or Virginian lungwort (*Mertensia Virginica* (L.) DC. (*Pulmonaria V.* L.), which, however, is smooth and has a pale-blue or white corolla. Lungwort has been suggested in the treatment of pulmonary tuberculosis and other chronic bronchial conditions, but its administration is probably of little or no benefit. Among the numerous other plants

which have been reputed to possess similar properties, are various species of *Onosmodium* (*False gromwell*), *Lithospermum* (*Gromwell*), *Echinospermum*, *Cordia*, *Piptocalyx*, and *Heliotropium* or *Heliotrope*.

BROMELIACEÆ.—The Pineapple Family.

This family, of some 40 genera and 500 species, many epiphytic, is of exceptional interest. The strange habits and great beauty of many of the plants render them very attractive. Its most important economic product is the pineapple, the fruit of *Ananas Ananas* (L.) Lyons (*Bromelia A.* L.; *Ananas sativus* Schult.), the dietetic value of which is far too little appreciated. Although the tough tissue of the green fruit is indigestible, the properly ripened fruit is not only thoroughly digestible, but contains a proteolytic enzyme which is usefully active in stomach and intestinal digestion. It also contains a milk-curdling ferment. The enzyme is more like trypsin than pepsin. It is separable from the neutralized juice by the action of sodium chloride or magnesium sulphate. The juice of the unripe fruit is astringent and anthelmintic, and is generally regarded as being an active abortifacient. Even ripe pineapples, eaten in excess, are known to have produced abortion. Legend has it that the juice of the green fruit is a powerful poison when introduced into the blood, and that the Malays and other eastern people so employ it upon their weapons, but we cannot learn that this view is supported. Its ferment, *bromelin*, which is closely related to *trypsin*, has the power of converting albuminous matter into peptone and proteoses. Bromelin is active between the temperatures of 30° and 60° C. (86° and 140° F.) either in acid, alkaline, or neutral media, but acids and alkalies are said to restrict its activity to some extent. It is destroyed by a temperature of 70° C. (158° F.). Pineapple syrup and essence are employed merely as flavoring agents. It is to be remembered that much of the pineapple extract used in flavoring is factitious, being made from butyrate of ethyl and alcohol.

Among the other products of this family, the following may be mentioned: The juice of *Bromelia pinguin* L. and of other bromelias is sharp and anthelmintic. The root of *B. karatas* is used in Paraguay as a sarsaparilla substitute under the name *Sarsaparilla Colorado* (*Red sarsaparilla*). *Hechtia argentea* Baker, of Mexico, yields an antiseptic gum-resin, and several Chilian species of *Puya* yield gums. The fruits of a number of species of *Ananas* and *Bromelia*, as well as of other genera, are edible. The *Black* or *Florida moss* (*Tillandsia usneoides* L.) and some other species, possess special qualities as packing substances, and the leaf-fibers of many species are utilized for cordage-making. Pineapple-juice has been recommended in the treatment of gastric indigestion, and has been used by the laity as a gargle for sore throat.

BROMOFORMUM, *U. S.*—Bromoform.

Bromoformium, P. G.; *Tribrommethane*, *Formyl tribromide*, E.; *Bromoform*, *Tribrommethan*, G.

Formula, $CHBr_3$. Molecular weight, 250.99.

A liquid consisting of 99 per cent. by weight of absolute bromoform and 1 per cent. of absolute alcohol. It should be kept in dark amber-colored, glass-stoppered bottles, in a cool place, protected from light.—U. S.

A colorless liquid having a chloroform-like odor, a sweetish taste, slightly soluble in water, readily soluble in ether and alcohol (P. G.).

Preparation.—60 parts of chlorinated lime (35 per cent. Cl) are made into a paste with water and added to 71.5 parts of potassium bromide dissolved in 150 parts of water, and the whole, after the addition of 12 parts of acetone, distilled in a current of steam until oily drops cease to come over. The apparatus is then cooled to about 45° C. (113° F.), and a second charge of 60 parts of chlorinated lime and 9 parts of acetone added and distilled as before. The operation is repeated thrice with successive charges of 60 parts of chlorinated lime and 6 parts of acetone. The collected distillates are washed with water, shaken with concentrated sulphuric acid, again washed with water, and the traces of remaining acid removed with sodium hydroxide solution. The purified bromoform is then dehydrated with fused calcium chloride, and finally submitted to distillation, collecting the portion distilling at 149°–150° C. (300.2°–302° F.) (Fromm). It may also be prepared by adding bromine gradually to a solution of potassium hydroxide in alcohol as long as the color is discharged, and then distilling it.

Properties.—Bromoform is a heavy, transparent, colorless, mobile liquid, with an ethereal odor, and a penetrating, sweet taste resembling chloroform. Specific gravity 2.808 at 25° C. (77° F.). It is very slightly soluble in water, but soluble in all proportions in alcohol, ether, benzene, and petroleum benzin, and in the fixed and volatile oils. Bromoform is slightly volatile at ordinary temperatures, and boils at 148° C. (298.4° F.), and solidifies at 6° C. (42.8° F.). It is not inflammable, but when

vaporized by the application of heat its vapor may be burned.—U. S. Pure bromoform is very apt to decompose on exposure to light and air, a property readily prevented by the addition of 1 per cent. of absolute alcohol, as directed in the U. S. P. The bromoform of the German Pharmacopœia congeals crystalline on cooling with ice and melts clear again at 7° C. (44.6° F.); boiling-point 148° to 150° C. (298.4°–302° F.); specific gravity 2.829–2.833; appears to contain a somewhat larger (4) per cent. of alcohol. Pure bromoform contains 94.854 per cent. of bromine, and may readily be recovered from admixture of organic matter by distillation in a current of steam, the distillate boiled after the addition of potassium hydroxide under a reflux condenser, and the resulting equivalent of bromide used for qualitative or quantitative determination. Heated with potassium hydroxide solution, carbon monoxide is evolved during the reduction to bromide.

Tests.—"If 10 Cc. of bromoform be evaporated in a dish over a naked flame, no solid residue should remain. If 10 Cc. of bromoform be well shaken with 10 Cc. of distilled water, and the liquids, upon standing, be allowed to completely separate, the water removed from the layer of bromoform should be neutral to blue litmus-paper (absence of free acid), and a portion should not produce a turbidity when treated with silver nitrate test-solution (absence of bromides and brominated compounds), and another portion treated with potassium iodide test-solution should not be tinted blue upon the addition of starch test-solution (absence of free bromine). If 10 Cc. of bromoform be well shaken with 10 Cc. of distilled water, and the liquids, upon standing, be allowed to completely separate, the water removed from the bromoform, treated with an excess of ammonium hydroxide, and then with a solution of iodine in ammonium iodide, until the black precipitate of nitrogen iodide, which may sometimes form, slowly disappears, it should not become milky in appearance, due to the separation of iodoform (absence of acetone).—U. S. On shaking 2 Cc. of bromoform and 2 Cc. of water with 0.5 Cc. of zinc-iodide-starch test-solution, the bromoform should not be discolored nor the starch turn blue. Shaken with an equal volume of concentrated sulphuric acid, not more than a light-yellow color should be developed within ten minutes.—P. G.

Action and Uses.—Bromoform, like its congener chloroform, depresses the reflex centers of the spinal cord, and so decreases their function. It produces sleep and insensibility to pain by its depressing action upon the cerebral centers governing those functions, but as an anæsthetic it has caused symptoms sufficiently alarming to prevent its employment for this purpose. It depresses the vasomotor center, causing a material decrease in blood-pressure, and in this way assists in the dissipation of heat. The pulse usually remains full and strong, as the heart and peripheral vagi are seemingly not affected by its administration. The drug is eliminated by the lungs and kidneys, the urine containing bromine several days after its employment.

When taken in overdose bromoform produces laughing intoxication, followed by nausea, vomiting, loss of reflex action, cyanosis of the face, and coma; at times collapse, cardiac failure, and extreme pallor may occur. Fatty degeneration of the viscera is also said to result from poisonous amounts. The use of external heat, the hypodermic injection of ether and strychnine, and the application of the faradic current, usually cause a return to consciousness in from 4 to 6 hours in such cases.

Bromoform is principally employed as a palliative in the treatment of whooping-cough. It decreases the number and intensity of the paroxysms, but does not shorten the course of the disease. It has also been recommended in hiccough, spasmodic asthma, laryngismus stridulus, and in the cough of phthisis and chronic bronchitis, and is said to have been successful in overcoming reflex headaches and vertigo. Locally applied, bromoform has been recommended for the relief of pain caused by tubercular ulceration of the larynx.

The dose for internal use is stated to be from 1 to 5 minims (0.05–0.3 Cc.). It is to be remembered, however, that a fluidrachm of bromoform contains about 360 drops. When used in pertussis, the beginning dose to a child one month old is 1 drop 3 times daily; under a year old, 3 drops; under 4 years old, 5 drops: all of which may be increased according to the intensity of the disease and the susceptibility of the patient.

BROMUM, *U. S.*, *P. G.*—Bromine.

Brôme, Fr.; *Brom*, G.; *Bromo*, It.

Symbol, Br. Atomicity univalent. Molecular weight, 79.36.

It should contain not less than 97 per cent. of pure bromine, and be kept in protected glass-stoppered bottles, in a cool place.—U. S.

Origin and Preparation.—Bromine was discovered by Balard (1826) in the mother-liquor obtained in the preparation of common salt from the water of the Mediterranean; he also investigated its chemical properties, and proved its close analogy to chlorine and iodine. Bromine does not exist in the free state, but is found widely distributed in nature, the bromides usually accompanying chlorides. It is found more particularly in sea water, in the waters of Kreuznach, Kissingen, and other mineral springs, but is now obtained in considerable quantities from the mother-liquors of many salt-works in the United States and at Stassfurt, Germany. These mother-liquors, which have been freed by crystallization as much as possible from other salts (chlorides and sulphates), contain the bromine, usually in combination with magnesium or calcium. These compounds are decomposed either by heating their solution with black manganese dioxide and hydrochloric acid, or by warming it to between 45° and 50° C. (113° and 122° F.) while chlorine gas is being passed into it; the bromides are at once decomposed: $MgBr_2 + Cl_2$ forms $MgCl_2 + Br_2$. The bromine volatilizes, and is condensed under a small quantity of water, which is contained in a deep Woulf's bottle kept cool by water, while that portion of bromine which escapes condensation is conducted into a solution of caustic potash contained in an open bottle; this solution, when it has nearly lost its alkaline reaction, is utilized subsequently for the preparation of potassium bromide. The mother-liquors, as obtained in Western Pennsylvania and West Virginia, yield about 0.5 per cent. of bromine, or the brine about 1 pound of bromine to 13 bushels of salt. The annual output of bromine in the United States is between 450,000 and 500,000 pounds, valued at about $135,000. The production in the German salt-works for 1897 was 490 tons.

Properties.—It is a heavy, brownish-red, mobile, and very volatile liquid, evolving at the ordinary temperature deep orange-red vapors, which are highly irritating to the eyes and lungs, and on being conducted into a flame impart to it a green color. Its odor, which is suggestive of chlorine and iodine, is suffocating and disagreeable, hence its name (from βρῶμος, a stench). It boils at 63° C. (145.4° F.) (Pierre). The melting-point of perfectly pure bromine is —7° C. (19.4° F.), but very small quantities of impurities lower the melting-point considerably. At 15° C. (59° F.) its specific gravity is 2.99, and at 0° C. (32° F.) it is 3.187; its vapor density (air = 1) is 5.4. It destroys cork, wood, etc., bleaches litmus and other coloring principles, and alters or destroys most odorous organic compounds. It dissolves in 28 parts of water at 25° C. (77° F.), and in less of alcohol and ether, with gradual decomposition of these liquids; the brown-red, or if diluted brown-yellow, solutions are bleached rapidly in the sunlight, hydrobromic acid being formed. Potassium bromide increases the solubility of bromine in water. Carbon disulphide, benzene, and chloroform dissolve bromine freely with an orange-red color, and, like ether, take it up from an aqueous solution on being agitated with the latter. When in contact with water at a low temperature, bromine forms a deep-red hydrate, $Br_2 + 10H_2O$, crystallizing in octahedrons or in scales, which at 15° C. (59° F.) are decomposed into bromine and water. Bromine and its solutions color starch-paste brown-yellow.

Impurities.—Commercial bromine may contain chlorine in the form of bromine chloride, BrCl, which may be removed by distilling in contact with ferrous or potassium bromide, $KBr + BrCl = KCl + 2Br$. Iodine is difficult to remove from bromine, but it does not often occur in it. German bromine is free from it. Carbon tetrabromide, when present in bromine, may be removed by careful distillation, as it has a higher boiling-point.

Tests.—Bromine should completely volatilize by exposure to air or to heat (absence of salts, etc.). If bromine be added to an excess of sodium hydroxide test-solution, it should combine to form a permanently clear liquid, without the separation of oily drops or the development of an odor resembling that of chloroform (absence of bromoform or other organic bromine compounds). If an aqueous solution of bromine be shaken with

a slight excess of reduced iron until it becomes nearly colorless, the filtered liquid, on the addition of a small amount of ferric chloride and of starch test-solution, should not assume a blue color (absence of iodine).—U. S.

Pharmaceutical Preparations.—AQUA BROMI, AQUA BROMATA. *Bromine water*, E.; *Bromwasser*, G.—The U. S. P. directs bromine water (for use as test-solution) to be prepared by dissolving 1 Cc. of bromine in sufficient water to make 100 Cc. Ordinarily, bromine water for use in chemical analysis is understood to be a stronger solution, 1 part in 50 by weight. If intended for medicinal purposes, bromine water should not be made stronger than 0.5 per cent., or 1 part in 200 by weight. It changes readily, but is more permanent than chlorine water, and should be kept in a dark place.

BROMIPINE.—This name has been applied to a 10 per cent. oleaginous solution of bromine, said to be made with oil of sesame, which retains almost entirely the physical characters of the oil, and does not suggest, by odor or taste, the presence of bromine. It is said to be particularly valuable in epilepsy, causing no disturbance of the stomach or bowels.

BROMOCOLL.—This preparation, also known as dibromotannic glue, is a compound of bromine, tannin, and gelatin, containing 20 per cent. of bromine in organic combination. It occurs as a faint, yellowish-brown, odorless and tasteless powder, which is almost insoluble in acid fluids, but is gradually dissolved in alkaline liquids, and is consequently absorbed in the intestines. It is employed also as a dusting-powder or in the form of an ointment.

Action and Uses.—Bromine is an irritant poison and a powerful escharotic. When given in overdose, it produces the symptoms common to other irritating substances, namely, burning pain in the mouth, œsophagus, and abdominal cavity, followed by collapse and death. Vomiting and purging may occur: the mucous membrane of the stomach is corroded and softened, and perforation of that viscus sometimes results. When locally applied to the skin in pure form, it produces deep and widespread destruction of the tissues, followed by slowly healing ulcers. Poisoning is treated best by the administration of ammonia water largely diluted, and demulcent drinks. Bodily temperature should be maintained in cases of poisoning by applying external heat, and opium be given for the relief of pain. Stimulation with atropine and strychnine should be given according to the indications.

Bromine is not largely employed in medicine at the present time. Formerly it was used in those conditions in which iodine is at present often given; for example, glandular enlargements, scrofulous ulcers, tertiary syphilis, bronchocele, chronic affections of the skin, amenorrhœa, depraved conditions of mucous membranes, and cardiovascular conditions characterized by high arterial pressure. Its local application was recommended by Dr. Goldsmith in the treatment of hospital gangrene, in which condition it was applied pure by means of a glass rod. A solution containing 30 minims (0.2 Cc.) in a pint of water has also been applied to chronic ulcers as a stimulating lotion, and has been proposed as a specific for poisoning by *Rhus radicans*. Superficial cancers have been treated by local injections of a strong solution in alcohol (1 in 3) or of bromine chloride, but this treatment is now abandoned. The topical use of bromine in diphtheria has been largely replaced by other more suitable remedies.

The internal dose of bromine is from $\frac{1}{10}$ to $\frac{1}{2}$ of a minim (0.005–0.010 Cc.), largely diluted with water, 3 times daily. Because of its volatility, care should be taken in removing the stopper from bottles containing bromine, lest it irritate the eyes or respiratory tract.

Two-thirds or more of the bromine manufactured is used for the preparation of bromides for medicinal use and photography, the rest being used for aniline dyes. For safer transportation and disinfecting purposes, *bromine blocks* have been recommended by Frank (1882), and consist of a porous mass formed by incinerating a mixture of diatomaceous earth with crude tartar or with calcium saccharate; cut into cubes of 45 Cc., these weigh about 30 Gm. and absorb 100 Gm. of bromine, which is very gradually given off on exposure. In this form bromine is sometimes called *solid bromine* or *bromum solidificatum*.

BRYONIA.—Bryonia; Bryony.

The dried root of *Bryonia alba* L. or of *Bryonia dioica* L. (Fam. *Cucurbitaceæ*).

White vine, Radix Uvæ Anguinæ, Devil's turnip, E.; *Zaunrübe, Gichtrübe*, G.; *Bryony Blanche*, Fr. Cod.; *Couleuvrée, Navel Fou*, Fr.; *Brionia*, Sp.

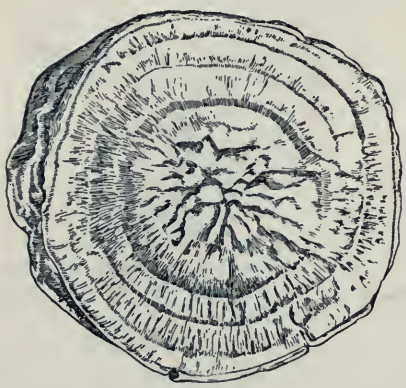
Origin.—Rough, slender, tendril-bearing, cucumber-like vines, of Europe. *B. dioica* has dicœcious flowers and red berries. *B. alba* has monœcious flowers and black

berries, and ranges more to the northward. In allusion to the color of its fruit, it is often called *Black bryony*, but this tends to confuse it with *Tamus communis* L., a plant not at all related. The long, tapering, fleshy, horseradish-like root is usually produced in sandy soil, and often weighs 4 or 5 pounds. Its surface is yellowish and marked with long transverse ridges, and it is whitish internally, with a strong, nauseous odor and a very bitter taste. It is usually cut into transverse or oblique slices to facilitate drying.

Description.—In circular transverse or oval oblique sections, 2 to 10 Cm. ($\frac{4}{5}$ to 4 In.) broad and mostly 6 to 12 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ In.) thick, little if at all thinner at the center, the edges dirty gray-yellow and irregularly circumferentially ridged, the transverse surface white or slightly yellowish-white, somewhat hard to the touch, annulate, radiate, the projecting wood-bundles continuous or interrupted; fracture sharp, whitish, mealy; odor slight but characteristic and disagreeable; taste bitter and nauseous.

No other drug, excepting possibly sliced arum or dracontium, neither of which has a radiate structure, bears even a remote resemblance to bryony.

Fig. 64.



Bryonia.

Constituents.—Bryony root contains starch, gum, sugar, wax, fat, malates, *bryoresin* which yields its active properties to water, and two glucosides, *bryonin* and *bryonidin*. Bryonin ($C_{34}H_{48}O_9$) is extremely bitter. On boiling with dilute acid, it yields bryoretin and hydrobryoretin, the former soluble, and the latter insoluble in ether. Bryonidin is bitter and poisonous, but has not been well studied. The substances formerly known as bryonin are mixtures of these two glucosides, or more or less purified extracts (Mankowsky, 1890). *Bryogenin*, a yellow amorphous resin, was obtained from bryonin by Masson in 1893. The genus contains about 8 species, and the roots of most of them appear to have been used widely.

Action and Uses.—Bryony was employed by the ancients as a purgative, diuretic, emmenagogue, and abortifacient. It is an active hydragogue cathartic, and when given in full dose causes gastro-intestinal inflammation with nausea and vomiting. Poisonous doses cause violent abdominal pain, due to irritation, with purging and vomiting. Mild delirium, vertigo, dilated pupils, failing circulation, profuse sweating, and a subnormal temperature, followed occasionally by death, have been recorded as the result of its ingestion in large doses. The effects of poisonous doses should be combated by the application of external heat and the administration of stimulants. Opium may be given to relieve pain.

Bryony is employed in atonic conditions of the gastro-intestinal tract. In dyspepsia resulting from a depressed condition of the peptic glands and in the constipation of children resulting from scanty secretion of the intestinal glands, in which state the stools are hard and friable, its administration is frequently attended with good results. Its exhibition is said to prevent serous effusions, especially those of the pleura, and also to aid in their absorption when present. It should not be given in the early stages of pleurisy, however, when the temperature is high. The drug is said to do good in chronic rheumatism, and is recommended as a hydragogue cathartic in dropsy. The fresh root when bruised and applied to the skin produces vesication, and in this way it has been employed in hydrarthrosis. *Bryonia alba*, by stimulating the capillaries, is said to be useful in controlling post-partum hemorrhages.

The dose of the powdered drug is from 20 grains to 1 drachm (1.30–4 Gm.), and of the tincture from 1 to 2 fluidrachms (4–8 Cc.). A mother-tincture, such as that prepared by the homœopaths, is probably the best preparation to employ, and may be given in doses of from 5 to 40 minims (0.30–2.6 Cc.).

BUCHU, *U. S.*—Buchu Leaves.

Buchu folia, Br.; *Buckublätter, Buccoblätter*, G.; *Folia Bucco, Folia diosmæ, Folia barosmæ, Feuilles de Bucco (Buoko, buchu)*, Fr.

The dried leaves of *Barosma betulina* (Thunb.) Bartling et Wendland (*Diosma b.* Thunb.—Fam. *Rutaceæ*).

Official in most pharmacopœias, some of which admit also *B. serratifolia* (Curt.) Willd. (*Diosma s.* Curt.).

Origin.—The buchus are from good-sized, erect, but widely branching shrubs of South Africa. Their properties and uses were learned from the Hottentots. They are usually imported in large bales.

Description.—From 10 to 25 Mm. ($\frac{2}{5}$–1 In.) long, and about two-thirds as broad, rhomboidally oval or obovate, abruptly contracted into a short, petiole-like base, blunt or obscurely notched at the recurved apex, sharply and finely dentate, thick and rigid, warped, brittle when dry, cartilaginous when moist, yellowish green, the surface glabrous and shining, coarsely and sparingly warty, with ascending veins and wrinkles; pellucid-punctate, a large gland near the base of each tooth; odor and taste strongly aromatic, somewhat mint-like; taste aromatic, slightly bitterish and pungent, and mucilaginous. The powder exhibits numerous yellowish sphæro-crystals, from the epidermal layer, and mucilage-cells.

B. crenulata leaves are very similar, but somewhat smaller and relatively narrower, more inclined to an oval form, and have the margin crenate.

FIG. 65.

Buchu leaves: *a, b, Barosma crenulata; c, d, B. betulina; g, h, B. serratifolia; e, f, Empleurum serrulatum.*—*b, c, f, g,* natural size.

Constituents.—Buchu leaves contain gum, resin, volatile oil, barosmin, hesperidin, etc. *Barosma betulina* yields 4.25 per cent. of dark olive-green, bitter oleoresin, with the odor of buchu, and equivalent to 1.2 to 1.45 per cent. of volatile oil. *B. crenulata* yields 3.76 per cent. of the same oleoresin, but containing about 1.6 per cent. of a probably identical volatile oil. *Barosmin* (or diosmin) is a bitter glucoside, soluble in ether, volatile oils, dilute acids and alkalies, scarcely soluble in cold alcohol, and crystallizing in microscopic needles. Oil of buchu contains 30 per cent. of the very peculiar crystallizable phenol *diosphenol* ($C_{10}H_{16}O_2$).

Impurities and Substitutes.—Buchu is apt to be contaminated with an excessive amount of the twigs, flowers, and fruits, and its efficiency thereby correspondingly diminished. The only important substitute is the so-called *Long buchu, B. serratifolia* (Curt.) Willd., once official and preferred to the other. This leaf is well illustrated in Fig. 65. It is very much thinner than the short variety, of a bright deep-green and a strong minty odor. It contains less than 1 per cent. of volatile oil, and this contains no diosphenol. It also yields less mucilage than short buchu.

Long buchu, in turn, is itself frequently substituted by, or contaminated with, the leaves of *Empleurum serrulatum* Ait., of the same family. These, also here figured, are usually distinguished by a yellowish-green color and a very acute tip, as well as by a somewhat different odor and taste. They are less mucilaginous, and contain less than 1 per cent. of volatile oil, without any crystallizable constituent.

Pharmaceutical Preparations.—FLUIDEXTRACT OF BUCHU, U. S. P.; COMPOUND FLUIDEXTRACT OF BUCHU, N. F.

Action and Uses.—Buchu is employed as a stimulant in certain morbid conditions of the genito-urinary tract. It should not be employed in acute inflammatory conditions,

but its use is advantageous in the treatment of subacute and chronic conditions in which the mucous membrane has lost its normal tone. It has been employed in chronic catarrh of the bladder, in chronic cystitis with incontinence of urine resulting from hyperacidity in pyelitis, in chronic urethritis, in retention of urine, and in diseases of the prostate gland. As it does not materially augment the urinary flow, its employment is of little benefit in conditions attended with dropsy. When first introduced into medicine, an ointment containing the drug was employed as a vulnerary, and a tincture was said to be useful in treating flatulent dyspepsia; at present, however, it is rarely employed for this purpose.

The dose of fluidextract of buchu is 1 fluidrachm (4 Cc.) 3 times daily to an adult, and from 10 to 30 minims (0.60–2 Cc.) to a child. An infusion, 1 ounce (30 Gm.) to the pint (480 Cc.), or one containing of buchu and uva ursi 4 fluidrachms (16 Gm.) each to the pint (480 Cc.), may be given in doses of from ½ to 2 fluidounces (16–60 Cc.).

BURSERACEÆ.—The Myrrh Family.

Genera, about 16; species, about 200; tropical shrubs and trees. Myrrh, Elemi, Olibanum, and Bdellium are elsewhere considered, and illustrate the family habit of producing oleoresins and gum-resins. The number of such which have been utilized medicinally or as incense is too great to allow of their consideration here. A number are considered in connection with the above-named drugs, others here follow:

Caranna gum is exuded by *Protium Carana* (H. B. K.) March. (*Icica C.* H. B. K.; *Amyris C.* H. B. K.), of tropical America. It is described as pitch-like when fresh, of balsamic odor and bitter and resinous taste, becoming brittle when dry, with a lustrous fracture and translucent in thin pieces. The West Indian article so-called, also known as *Chibou* or *Cachibou resin*, is from *Bursera gummifera* L., the *Gumbo-limbo* or *West Indian birch* (*Gommert*, Fr.). Caranna gum may be employed for the same purposes as Tacamahaca resin.

Tacamahaca resin or **gum** is a name applied to a number of tropical American exudations which are closely similar to one another, though apparently derived from a number of different trees, the following having been named: *Protium heptaphyllum* March. (*Icica h.* H. B. K.; *I. Tacamahaca*; *Amyris ambrosiana* W.); *P. altissimum* March. (*Icica a.* Aubl.); *Bursera tomentosa* Tri. et Pl. (*Elaphrium t.* Jacq.; *Fagara octandra* L.). This substance is very similar to Caranna gum, but usually lighter-colored and with a distinct odor. The East Indian Tacamahacas do not pertain to this family. Tacamahac possesses properties in common with the terebinthinates. It is no longer employed in internal medicine. The oil obtained from the seeds, and plasters containing the resin, have been used in treating muscular rheumatism.

Goqui, Bélám-pú, or **Pan Oleoresin,** is yielded by *Santiriopsis balsamifera* Engl., of San-Thomé.

Gommier or **Incenso.**—Several West Indian products of this family are there traded in under these names. The *G. rouge* of Dominica, or *G. à Canots* of Santa Lucia, appears to come from *Dacryodes hexandra* Griseb.; the *G. à l'encens* of Santa Lucia is one of the Tacamahacas (*T. huilense inicolore*), and is from *Protium Guianense* March.

Hedwigia balsamifera Sw. (*Bursera b.* Pers.; *Tetragastris b.* Sw.), of tropical America, is remarkably productive of active substances. It exudes a balsam (*B. de cachou* or *B. de Sucrier*) which is used like copaiba. Its seeds yield an oil much like that of sweet almonds. Its bark (called *Copalchi* or *Campanilla* in Mexico) contains an alkaloid which is powerfully convulsant and a heart poison, while its resin is a powerful depressant of the nerve-centers. Copalchi bark has been substituted for both cinchona and cascarilla. It is said to be tonic, aromatic, and antiperiodic, and capable of asserting itself in the treatment of mild intermittent fevers. An infusion made with 1 ounce (30 Gm.) of the drug in 1 pint (480 Cc.) of boiling water may be given in the dose of from ½ to 1 fluidounce (16–30 Cc.), 3 times daily.

A number of aromatic woods also are yielded by the *Burseraceæ*. One sort of linaloe or aloes wood is yielded by *Bursera fagaroides* Engl. Colophon wood is from *Bursera paniculata* Lam., of Mauritius. The wood of *Marignia obtusifolia* DC. (*Bursera o.* Lam.; *Protium o.* Lam.) is sold as *Bastard colophon.*

BUTYL-CHLORAL HYDRAS, *Br.*—Butyl-chloral Hydrate.

Butylchloralum hydratum, Chloralhydratum butyli, Chloral butylicum. Hydrous butyl-chloral; Trichlorbutylidene glycol; Croton-chloral hydrate (wrongly so called), E.; *Hydrate de chloral butylique,* Fr.; *Butylchloralhydrat, Trichlorbutylaldehydhydrat,* G.

Formula, $C_4H_5Cl_3O + H_2O$, or $CH_3.CHCl.CCl_2.CH(OH)_2$. Molecular weight, 191.94.

Butyl-chloral hydrate was discovered by Kramer and Pinner in the by-products resulting in the manufacture of chloral, and later found by R. Schiff to exist in 2 isomeric forms distinguishable by the difference in the melting-points of the various

amides of the same. It was originally misnamed "croton-chloral hydrate," owing to its supposed relationship to crotonic acid, until Pinner proved it to belong to the butyl series and corrected the error.

Preparation.—Dry chlorine gas is conducted into aldehyde, or paraldehyde, cooled to a low temperature, about —9.5° C. (15° F.), until the aldehyde is saturated. The current of gas is then continued at a gradually increasing temperature to about 100° C. (212° F.), the resulting product being washed with sulphuric acid and submitted to fractional distillation, collecting the portion distilling at 163°–165° C. (325.4°–329° F.), which is *butyl-chloral*, $C_4H_5Cl_3O$, a dense, oily liquid. The latter is mixed with water in the ratio of 9 to 1, and when the mass has crystallized it is recrystallized from boiling water.

Properties.—Thin, white, glistening laminæ or scales, having a sweetish melon-like odor, and a burning, bitterish taste; melt at 78° C. (172.4° F.); specific gravity 1.69; dissolve in 30 parts (50 parts, Br.) of cold water, more soluble in hot water and water containing glycerin; soluble in its own weight of glycerin or 90 per cent. alcohol and in 20 parts of chloroform, Br.; readily soluble in alcohol and ether. It does not yield chloroform when heated with solution of potassium hydroxide (distinction from chloral hydrate).—Br. Alkalies decompose it successively into *propylic chloroform*, $C_3H_5Cl_3$, and *dichloride of allylene*, $C_3H_4Cl_2$, the latter producing the medicinal effects attributed to butyl-chloral hydrate. From a solution in alcohol it is precipitated by the gradual addition of water, in the form of globules consisting of butyl-chloral alcoholate, $C_4H_5Cl_3O.C_2H_5HO$. Yellow ammonium sulphide added to an aqueous solution of butyl-chloral hydrate produces a yellow to orange-yellow color, which is hastened by heating to the production of a reddish-orange-colored precipitate in solutions not too dilute (Ogsten).

Tests.—Butyl-chloral hydrate should be neutral to litmus in alcoholic solution, and give no precipitate with test-solution of silver nitrate. Mixed with concentrated sulphuric acid and gently warmed, no discoloration should result. When butyl-chloral hydrate is melted with acetamide, 2 isomeric butyl-chloral-acetamides, $C_6H_{10}Cl_3NO_2$, are formed, the *α*-form being soluble in hot alcohol and melting at 158° C. (316.4° F.), and the *β*-form soluble in dilute alcohol and melting at 170° C. (338° F.) (Schiff, *Ber.*, 25, 1690–1691).

Action and Uses.—The physiological action of butyl-chloral hydrate closely resembles that of chloral itself (which see). Its indications, contraindications, the symptom-complex resulting from overdose, and treatment of poisoning by this drug, are practically identical with those of the latter drug. It possesses more analgesic and anæsthetic power, however, than chloral, and Liebreich states that 1 drachm (4 Gm.) produces deep sleep, anæsthesia of the head, and loss of irritability of the fifth pair of nerves. This last statement is disputed by von Mering. Upon the heart it is much less of a depressant than chloral, and may therefore be substituted for chloral when the indications for the use of the latter are contraindicated by cardiac disease. It is an excellent palliative in the treatment of tic douloureux, migraine, and facial neuralgia. Headaches resulting from eyestrain, associated with nausea, or caused by anæmia, are sometimes benefited by its use. As a palliative it may do good in sciatica and dysmenorrhœa, and its administration in insomnia accompanied by pain is frequently attended with success.

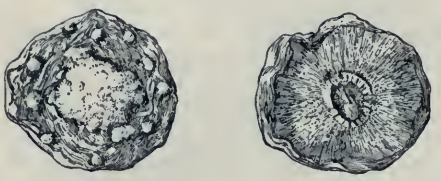
The dose as a hypnotic is from 5 to 20 grains (0.30–1.30 Gm.), given in pills or in syrup or elixir. For the relief of pain it may be given in doses of from 3 to 5 grains (0.20–0.30 Gm.) every 2 hours until relief is afforded or sleep produced. As much as 1 drachm (4 Gm.) has been given at a dose, but as a rule 30 grains (2 Gm.) should be considered the maximum dose. A mixture containing from 5 to 10 parts of the drug, 20 parts of glycerin, and 130 parts of distilled water, has been recommended in doses of ½ fluidounce (16 Cc.), repeated in 5 minutes, and again in 10 minutes, unless relief is afforded; but it is not certain that this amount is always safe, and it should be given with caution.

C.

CACTACEÆ.—The Cactus Family.

Genera about 20; species upward of 600, chiefly inhabiting arid and barren localities, their leaves therefore metamorphosed into spines, the stems green, fleshy, and succulent. Many species which are wanting in the spiny armature, secure protection by means of poisonous constituents, chiefly alkaloids, against desert animals, which seek them for their thirst-quenching and nutritive properties. Their fruits are berries, and very many of them, like the *Tunya*, are edible.

FIG. 66.



a *b*

Anhalonium, slightly swollen by soaking: *a*, upper, *b*, lower surface (½ Nat.).

But few of the species have been utilized in medicine, although others are quite likely to become so. In addition to *Cereus*, elsewhere considered, the following deserve attention:

Anhalonium (*Mescale-* or *Muscale-buttons; Pellote*) is the dried tops of the plants *Lophophora Williamsii* (Lem.) Coulter (*Anhalonium W.* Lem.) and *L. Lewinii* (Henning) Rusby (*Anhalonium L.* Henning; *Mammillaria L.* Auct.; *L. Williamsii Lewinii* Coulter). These plants grow in inaccessible places, especially on limestone cliffs, at high altitudes, in northern Mexico. They possess small cylindrical or ovoid stems a few inches in length and almost equally as broad, only the upper portion projecting above the surface of the ground, as a flattened or slightly convex green disk, bearing numerous triangular, radially flattened fleshy lobular appendages, somewhat spirally arranged. These aërial portions, an inch or less in height, are sliced off and dried. They are thus greatly reduced, both in breadth and thickness, so that they become button-shaped disks, mostly 1 to 2 inches in breadth and about ⅛ to ¼ of an inch in thickness, roughened on the lower surface by the wrinkling produced in drying, and upon the upper surface by the fleshy lobules above referred to and by a central tufted mass of yellowish or whitish hairs occupying about one-third of the total breadth. In the midst of these hairs several pink flowers are commonly found. The two species are readily distinguished by the character of this central hairy mass. In *L. Williamsii* the hairs are in tufts more or less distinct from one another, whereas in *L. Lewinii* they are massed together, shorter (6 to 9 Mm.—¼ to ⅓ In. long) and of a more dirty or yellowish-white color. Rarely, some dried fruits, about as large as dried currants, are also found. The plants contain very powerful alkaloids. That of *L. Williamsii*, amounting to nearly 1 per cent., is *pellotine* ($C_{13}H_{19}NO_3$). It occurs in colorless transparent flakes, melting at 110° C. (230° F.) and dissolving in sulphuric acid with a yellowish color, becoming red with nitric acid. *A. Lewinii* contains *anhalonine* ($C_{12}H_{15}NO_3$), very similar to pellotine; *mescaline* ($C_{11}H_{17}NO_3$), *anhalonidine* ($C_{12}H_{15}NO_3$), and *lophophorine* ($C_{13}H_{15}NO_3$). Although these two species are chiefly used, others are said to be similarly employed. *Anhalonium fissuratum* contains a very small amount of the alkaloid *anhaline* ($C_{10}H_{17}NO$), which crystallizes in colorless, stellate prisms and melts at 115° C. (239° F.). With sulphuric acid it gives a colorless solution, green on the addition of nitric acid. With nitric acid it is yellow, changing to orange-red with potassium hydroxide. *A. prismaticum* is said to contain an exceedingly poisonous alkaloid. Experiments made upon animals with anhalonium prove that it is a powerful narcotic poison. When moderate amounts are given to man, it first increases reflex excitability, and later the patient passes into quiet sleep. The respiration is primarily depressed, but later becomes full, deep, and regular. It at first weakens the circulation, but later increases the force and diminishes the rapidity of the heart's beat. Blood-pressure is increased, and the pulse is full and forcible. Lethal doses produce intense muscular spasm, especially of the abdominal muscles and the diaphragm, followed by tetanic convulsions resembling those caused by overdoses of strychnine, death occurring from respiratory failure, while the heart stops in diastole almost simultaneously. This drug has been recommended as a heart stimulant and tonic, and is said to be an excellent adjuvant to digitalis. It has also been employed as a respiratory stimulant in those conditions in which strychnine proves beneficial. It is further stated that the drug possesses narcotic properties resembling those of opium. Anhalonium has been given with asserted success in pneumothorax, advanced tuberculosis, and angina pectoris. The beginning dose is from ½ to 1 minim (0.025–0.05 Cc.) of the fluidextract, which may be gradually increased to 2 or 3 minims (0.10–0.20 Cc.).

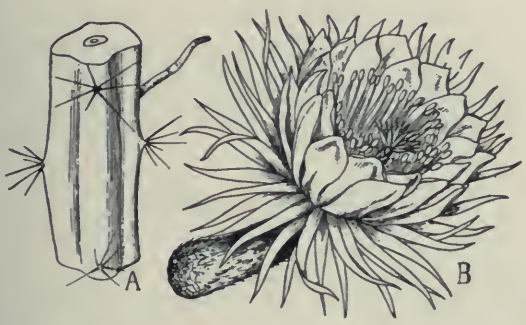
Alkaloids have also been encountered in *Mammillaria centricirrha* Lem. and in *Echinocactus mammillosus* Lem. *Rhipsalis Cassytha* Gærtn., of the West Indies, is anthelmintic, as is the fruit of *Opuntia Opuntia* (L.) Coulter (*Cactus O.* L. ; *Opuntia vulgaris* Mill.). Several species, in widely separated genera, yield tragacanth-like gums, and one, *Cereus gummosis*, is rich in saponin (see also CACTUS).

CACTUS.—Cactus.

Night-blooming cereus, Sweet-scented or Vanilla cactus, E.; *Kaktus, Fackeldistel, Königin der Nacht*, G.; *Cactier, Cierge a grandes fleurs*, Fr.

Cereus grandiflorus (L.) Miller (*Cactus g.* L.—Fam. *Cactaceæ*). No precise definition can be assigned to this title, since the activity of the plant has not been located. The

FIG. 67.



Cactus grandiflorus (stem, Nat.; flower, $\frac{1}{4}$). (After Holmes.)

fresh stem has been used, but the evidence is pretty conclusive that this has little, if any, activity. The flower has been largely used, but competent authorities, employing an undoubtedly genuine article, have rendered contradictory reports as to its activity. From this it appears to follow that the activity must be confined to the flower in some special stage of development, or to certain parts of it, or to some part gathered with it.

Origin.—A plant of the West Indies, with a weak, prostrate or ascending, green and fleshy, 5- to 7-angled, spiny stem, and an acrid juice, producing very large and remarkably fragrant, white, nocturnal flowers. It is largely cultivated in greenhouses.

Description.—Stems (Fig. 69, A) in pieces of varying length, about $1\frac{1}{2}$ to 2 Cm. ($\frac{3}{5}$ to $\frac{4}{5}$ In.) in diameter, cylindrical, with 5 to 7 angles, furnished along the angles at intervals of about 2 Cm. ($\frac{4}{5}$ In.) with small tufts of 6 to 8 spines about 2 Mm. ($\frac{1}{12}$ In.) long, and at irregular intervals of 5 to 15 Cm. (2 to 6 In.) or more, with a branched root. Internally, the transverse section presents a central woody ring about 3 Mm. ($\frac{1}{8}$ In.) in diameter, the remainder of the stem presenting a spongy parenchyma with numerous large crystals or "spæraphides," immersed in it (*after Holmes*).

The bud at first is globose, acute, then clavate, sessile, covered with imbricated scales bearing long setæ. When fully expanded, the flower is a span across; the tube of the calys is long, green, the limb cup-shaped; the former is composed of the imbricated scales above mentioned; the latter is formed of numerous long, spreading, tawny-orange upper calyx segments, forming a sort of ray, and of an inner series of petals, which are oblong, broader upward, nearly erect, and of a pure white color. Stamens numerous, long, at length inclined to one side. Filaments white; anthers linear, oblong, yellow; style as long as the stamens; stigma of many rays (*Bot. Mag.*).

Adulterants.—Holmes has found a triquetrous stem and the flowers of *Opuntia decumana* Haw, as adulterants, and others are doubtless used. The flowers last named have their largest petals only about three-fourths of an inch long, more than double the length of the stamens, while the petals of the genuine are 2 or 3 inches long, and the stamens fully three-quarters as long.

Constituents.—We have only indefinite knowledge of the constituents of the drug. Parr reported "Some waxy and fatty bodies, several acid, slightly acrid, glucosidal resinous bodies, and also an alkaloid, which is present in very small quantities only."

Action and Uses.—When locally applied to the skin, the fresh juice of the cactus produces vesication and occasionally pustulation. The drug has long been employed by

the native population as a remedy for dropsy, but its chief use at present is in the treatment of cardiac disease. It stimulates the cardiac muscle, the accelerator nerves, and the motor ganglia of the heart, thereby increasing the force and frequency of the heart's action. The increase in blood-pressure is due both to its stimulating effect upon the vasomotor center and to the above-named action upon the heart. Cactus is also said to increase reflex action by its stimulating effect upon the spinal centers. It is stated that it does not cause a cumulative effect nor produce gastric disorder. Cactus is employed as a substitute for digitalis in those cases in which the latter remedy seems to be inefficient. It may be tried in the treatment of cardiac palpitation and weakness, and also in valvular disease of the heart. It is said to be especially useful in aortic regurgitation, as it does not prolong diastole. Certain cases of angina pectoris and the low fevers are also said to be benefited by its employment.

The ordinary dose of the tincture is from 2 to 8 minims (0.10–0.50 Cc.); of the fluid-extract, from 1 to 4 minims (0.05–0.25 Cc.), but much larger doses are often used.

Other Species.—The juice of *C. flagelliformis* Mill. is said to be anthelmintic. That of *C. divaricatus* (Lam.) DC. is used as an epispastic and internally as an anthelmintic and diuretic. *C. Petayaya* (L.) DC. is used as a diuretic. The stem of *C. Peruvianus* Mill. is said to contain an alkaloid. The fruit of *C. geometrizans* Mart. is reported diuretic and antipyretic.

CADMIUM.—Cadmium.

Cadmium, Fr., G.; *Kadmium*, G.

Symbol, Cd. Atomicity bivalent. Atomic weight, 111.6.

Origin and Preparation.—This metal is found near Bishopstown, Scotland, in the form of sulphide as the mineral *greenockite*, but it is more frequently present in small quantities in some kinds of calamine, blende, and other zinc ores. It was discovered by Stromeyer and Hermann in 1817. Cadmium being more volatile than zinc, it is contained in the first portions obtained in the distillation of the latter metal, and its presence is indicated by the appearance of a brown flame (the so-called "brown blaze") before the greenish-white flame of burning zinc is noticed. To obtain cadmium, the zinc, or the zinc oxide containing it, is dissolved in dilute sulphuric or muriatic acid, and the cadmium precipitated by metallic zinc; or the acid solution is treated with hydrogen sulphide to precipitate the cadmium as yellow sulphide, which is used as a pigment under the name of *cadmia;* the sulphide is dissolved in strong hydrochloric acid, the solution precipitated by excess of ammonium carbonate to remove copper and traces of zinc, and the washed and dried precipitate mixed with lampblack and distilled.

Properties.—Cadmium is a malleable and ductile metal having the color of tin, and like the latter it emits a crackling sound when bent, It crystallizes readily in octahedrons, is superficially tarnished on exposure to the atmosphere, becomes brittle at 82° C. (180° F.), fuses near 315° C. (599° F.), and volatilizes at 860° C. (1580° F.). Its density varies between 8.60 and 8.69; its vapor is dark-yellow, has a nauseous taste, and burns with a dark-red flame to brown oxide. In acetic, hydrochloric, and dilute sulphuric acids it dissolves more slowly than zinc, with evolution of hydrogen. It is easily soluble in dilute nitric acid, with evolution of nitric oxide, NO.

The salts of cadmium are mostly white; those soluble in water have an acid reaction and a disagreeable metallic taste. The solutions, treated with hydrogen sulphide or ammonium sulphide, afford an orange-yellow precipitate of CdS, which is insoluble in an excess of the precipitant and in dilute acids and alkalies. Caustic alkalies produce a white precipitate of $Cd(OH)_2$, which is soluble in ammonia, but not in potassium or sodium hydroxide. The soluble carbonates, phosphates, and oxalates, and potassium ferrocyanide produce white precipitates.

Tests.—The impurities likely to be present in metallic cadmium are mainly zinc and copper, the former of which is recognized by precipitating the solution in nitric acid with hydrogen sulphide, when the filtrate from the bright orange-yellow precipitate will yield a white precipitate on the addition of ammonia and ammonium sulphide. When the solution in nitric acid is precipitated by slight excess of ammonium carbonate, the filtrate will have a blue color if copper be present.

Uses.—As a constituent of several alloys and to prepare cadmium salts.

SALTS OF CADMIUM.

Cadmii Bromidum.—*Cadmium bromide*, E.; *Bromure de cadmium*, Fr.; *Cadmiumbromid*, *Bromcadmium*, G. $CdBr_2 + 4H_2O$.—Obtained by acting on granulated metallic cadmium under water with bromine, letting the mixture stand, with occasional shaking, in a warm place until the color of bromine disappears. Filter and evaporate to crystallization. It forms colorless, shiny, transparent prismatic needles, easily soluble in water and alcohol. It loses all water of crystallization at 260° C. (500° F.). It contains 37.21 per cent. of oxide and 46.51 per cent. of bromine. For test for impurities, see Cadmium Iodide.

Cadmii Iodidum.—*Cadmium iodide*, E.; *Iodure de cadmium*, Fr.; *Cadmiumiodid*, *Jodcadmium*, G. CdI_2.—It may be prepared like cadmium bromide or by dissolving 20 parts of potassium iodide and 15 parts of cadmium sulphate in water, evaporating the solution to dryness, exhausting the residue with warm absolute alcohol, and filtering and crystallizing (A. Vogel, 1863). By the first process a direct combination of the metal and iodine is effected, while in the second process a mutual decomposition of the two salts takes place, with the formation of cadmium iodide and potassium sulphate. The latter, being insoluble in alcohol, remains upon the filter: $CdSO_4 + 2KI$ yields $CdI_2 + K_2SO_4$. Cadmium iodide occurs in white, flat, micaceous crystals of a pearly luster, inodorous, of a nauseous metallic taste, permanent in the air, soluble in alcohol, and at the ordinary temperature in a little more than its own weight of water. Heated to about 310° C. (600° F.), it forms an amber-colored liquid, and at a dull-red heat is decomposed, vapors of iodine being given off. The aqueous solution, which reddens litmus, yields with hydrogen sulphide a yellow precipitate of CdS, which is insoluble in ammonium sulphide (difference from arsenic), and the filtrate from this precipitate is not affected by ammonia, ammonium sulphide or carbonate (absence of the metals of the zinc group and of the earths and alkaline earths), and after applying these tests leaves no residue when evaporated to dryness and ignited (absence of alkalies). The presence of heavy metals would be indicated by the brown or blackish discoloration in the yellow color of the precipitated sulphide. Ammonia would be detected by the odor given off on the addition of an excess of potassium hydroxide solution. Most other cadmium salts differ considerably from the iodide in appearance. Cadmium iodide is said to be superior to lead iodide in the treatment of chronic diseases of the skin, scrofulous enlargements of glands, and chronic joint-affections. It is usually applied in the form of an ointment containing from 30 grains to 1 drachm (2–4 Gm.) of the salt in 1 ounce (30 Gm.) of lard. Unguentum Cadmii Iodidi was formerly official in the British Pharmacopœia, and was made by triturating 62 grains of cadmium iodide with 1 ounce of simple ointment.

Cadmii Salicylas.—*Cadmium salicylate*, E.; *Salicylate de cadmium*, Fr.; *Cadmiumsalicylat*, *Salicylsaures Cadmium*, G. $(C_6H_4(OH)CO_2)_2Cd$.—It may be prepared by warming salicylic acid in 30 times its weight of water and adding cadmium carbonate until the solution is very slightly acid, evaporating to less than half of the volume and letting stand to crystallize. It forms colorless, neutral or slightly acid, tabular crystals, soluble in 68 parts of cold and 24 parts of hot water, in alcohol, ether, and warm glycerin, insoluble in chloroform. An aqueous solution is colored violet by ferric chloride. Cadmium salicylate is a very active antiseptic, and has been recommended in the treatment of purulent ophthalmia.

Cadmii Sulphas.—*Cadmium sulphate*, E.; *Sulfate de cadmium*, Fr.; *Cadmiumsulfat*, *Schwefelsaures Cadmiumoxyd*, G. $3CdSO_4.8H_2O$.—It may be prepared by bringing together 2 parts of cadmium, 10 parts of water, 2 parts of sulphuric acid, and 1 part of nitric acid, to facilitate the action: $3Cd_2 + 6H_2SO_4 + 4HNO_3 = 3CdSO_4 + 8H_2O + 4NO$. At the end heat is applied and the whole evaporated to dryness to expel any acid. The residue is dissolved in water, filtered, and crystallized. Salts containing different quantities of water of crystallization are formed under varying conditions of temperature. Cadmium sulphate crystallizes in colorless rhombic prisms, which effloresce somewhat in the air, have an astringent and strongly metallic taste, and change the color of blue litmus-paper to red. It dissolves at 23° C. (73.4° F.) in 1.6 parts of water, is somewhat more soluble in hot water, and is insoluble in alcohol; at 100° C. (212° F.) it loses 11.8 per cent. (5 molecules) of water, and the remainder when heated to redness; at a full red heat one-half of the acid is also expelled. Cadmium sulphate is an irritating astringent and emetic. If given internally in overdose, it causes severe gastro-intestinal pain, with profuse ptyalism, nausea, and vomiting. The respiration and circulation are depressed, and vertigo, fainting, and convulsions sometimes ensue. The drug has been recommended as an astringent in the treatment of chronic conjunctivitis, chronic gonorrhœa, and gleet, and is said to be beneficial also in treating otorrhœa and opacities of the cornea. It may be prescribed either in solution containing from 1 to 4 grains (0.05–0.25 Gm.) of the salt in 4 fluidounces (120 Cc.) of water, or in an ointment made by triturating 1 to 2 grains (0.05–0.10 Gm.) of the drug with 1 drachm (4 Gm.) of fresh lard.

CÆSIUM—Cæsium. RUBIDIUM—Rubidium.

Symbols, Cs and Rb. Atomic weights, 131.90 and 84.8.

Both these elements are widely distributed, but only in small quantities. They generally occur in company with potassium, which they resemble closely. Bunsen and Kirchhoff discovered them by the spectroscope, the characteristic spectrum of rubidium being 2 dark-red lines, hence the name of the metal, from *rubidus*, dark-red, while cæsium was given its name because of 2 blue lines in its spectrum, from *cæsius*, sky-blue. Cæsium occurs in 2 minerals, namely, *castor* and *pollux* (cæsium-aluminum silicate), and also accompanies rubidium in very small quantity in the water of the Dürkheim and Nauheim springs. Rubidium occurs in *carnallite* of the Stassfurt beds, and is obtained, as rubidium alum, from the mother-liquors after the potassium chloride is crystallized out. It occurs also in *lepidolite*, a variety of mica. The isolation of these metals is difficult and tedious. Cæsium was isolated first by Setterberg in 1881. It has a density of about 2, melts at 26.5° C. (79.7° F.), and takes fire in air at ordinary temperature. Its salts are much like those of rubidium and potassium, and it is the most electropositive of all metals. Rubidium is silvery-white, with high luster, takes fire in air, decomposes water with greater energy than does potassium, and melts at the temperature of the body. Rubidium hydroxide, Rb(OH), has even stronger basic properties than potassium hydroxide. Both rubidium and cæsium have a marked power of forming double salts. C. Chabrié prepared and described a number of cæsium salts about which hitherto there has been very little exact information (*Comptes rend.*, 132, p. 678, 1901).

Action and Uses.—The salts of these two metals are said to increase blood-pressure, and slightly to decrease the rapidity of the heart's action. Cæsium bromide has been employed in doses of from 3 to 5 grains (0.20–0.30 Gm.) in the treatment of cardiac palpitation resulting from nervousness. The other salts have all been recommended as anti-epileptics. Cæsium-rubidium-ammonium bromide is probably the most popular salt, and is given in daily doses of from 30 to 45 grains (2–3 Gm.).

CÆSIUM AND RUBIDIUM SALTS.

Cæsium-ammonium Bromide. $CsBr.3NH_4Br$.—This double salt exists as a white soluble powder.

Cæsium Bromide. CsBr.—A white, granular powder soluble in water.

Cæsium Carbonate. Cs_2CO_3.—A white granular mass, hygroscopic, and soluble in water and alcohol.

Cæsium Sulphate. Cs_2SO_4.—Colorless prisms, permanent in air, very soluble in water, but not in alcohol.

Cæsium-rubidium-ammonium Bromide. $(CsRb)Br_2 3NH_4Br$.

Rubidium-ammonium Bromide. $RbBr.3NH_4Br$.—A white crystalline powder, soluble in water, containing 36 per cent. of rubidium bromide.

Rubidium Bromide. RbBr.—Transparent soluble crystals, which may be substituted for potassium bromide in medicine.

Rubidium Iodide. RbI.—Colorless cubical crystals, very soluble in water, recommended as a substitute for potassium iodide.

CAFFEA.—Coffee.

Semen Coffea.—Kaffee, Kaffeebohnen, G.; *Café*, Fr.

The dried ripe seed of *Coffea Arabica* L. or of *C. Liberica* Hiern. (Fam. *Rubiaceæ*).

Origin.—The coffee plants are large shrubs or small trees, the first-named native of northeastern Africa, and possibly also of Arabia, the second of the west coast of Africa; *C. Arabica*, of cultivation, yields almost the whole of our commercial coffee, the most coming from Brazil, the best probably from Guatemala. Java and India also yield large quantities, and cultivation is carried on to a greater or less extent in nearly all tropical countries which offer a suitable climate. The best results are attained at a considerable elevation, from 2000 to 4000 feet, in southern India. The plant is greatly subject to disease under adverse conditions. *C. Liberica* can be grown down to the sea-level, and it is much hardier and more capable of resisting disease. The genus contains some 25 species, all of the old world, and mostly African. Several others besides the two

mentioned are somewhat cultivated, but the products can scarcely be considered commercial.

The coffee plant is very handsome. Its snowy-white and fragrant flowers are closely clustered in the axils of the opposite, coriaceous, dark-green and shining leaves, and are frequently present toward the summit of the long and slender branches, while the fruits, both the green and the bright-red ripe ones, are present below. The fruit is an oval, deep-purple, 2-seeded drupe, each seed enclosed in a parchment-like endocarp, the 2 placed together by their flat, longitudinally grooved sides. The Liberian coffee plant has the corolla 6- to 9-lobed, and the fruit globular and much larger.

When the fruits are ripe, they are gathered and freed from the scanty pulp by suitable apparatus and washing; the seeds are then dried and subsequently freed from the parchment-like husk (*putamen* or *endocarp*) by passing them between wooden rollers and winnowing. The seeds then constitute one-third the weight of the ripe berries.

Description.—The seeds are oval, longitudinally grooved upon the flat side, usually almost completely deprived of the parchment-like, finely wrinkled endocarp, fragments of which remain in the groove. The horny perisperm is of the shape of the seed, according to the variety, of a yellowish, brownish, bluish, or greenish tint, and is folded, or rather rolled up, whereby the groove is produced. The embryo is situated under the convex side, near the end, is slightly curved, and occupies about one-fourth the length of the seed. Raw coffee has a very faint odor and a sweetish, slightly astringent, and bitterish taste. The commercial varieties vary considerably in flavor, in size, and in the shade of color. On keeping, coffee loses during the first year about 8 per cent. in weight, principally moisture; during the second, 5 per cent.; and during the third year, 2 per cent., the flavor being at the same time greatly improved.

Constituents.—The most important constituent of coffee, from a medicinal point of view, is its *caffeine* (see CAFFEINA), the amount of which ranges from a little less than 1 to a little more than 2 per cent., as shown by the appended table. With this, there is an exceedingly variable amount of *caffeo-tannic* (*chlorogenic*) *acid*, yielding *caffeic acid* by precipitation with lead salts and baryta, and by other processes; about 15 per cent. of sugar, the most of it very similar to glucose, the rest dextrin; about 13 per cent. of fat (olein and palmitin), and an equal amount of proteids, with a trace of volatile oil. It yields 4 to 5 per cent. of ash; Mocha coffee, as much as 7.84 per cent., consisting chiefly of potassium, sodium, magnesium, and calcium carbonates and phosphates, the earthy salts amounting to one-seventh or one-sixth of the weight. There is about 12 to 15 per cent. of moisture. With the caffeo-tannic acid, there is believed to be a small amount of citric acid. Caffeo-tannic acid is amorphous and gum-like. Caffeic acid ($C_9H_8O_4$) occurs in straw-yellow crystals. Both yield protocatechuic acid when fused with potassa. A small amount of kinic acid has been obtained. The caffeine apparently exists partly free and partly in combination with caffeic acid. *Caffeanic*, *cærulic*, and *caffeelic acids* are considered oxidation-products, and *viridinic* acid, and chlorogenic acid, in part, are regarded as mixtures of them.

Foster and Reichelmann report another alkaloid than caffeine in coffee, which is amorphous and insoluble in chloroform.

Gaucher has shown that caffeo-tannic acid is present in all parts of the plant, but that caffeine exists in appreciable quantities only in the mesophyll of the leaves, in the embryo, and in the endosperm. He finds the best test for the alkaloid to be a saturated solution of ammonium molybdate and ammonium chloride, giving a white amorphous precipitate which turns blue on drying.

The roasting of coffee, which is best accomplished at a temperature of about 250° C. (482° F.), renders the seeds pulverizable, and at the same time gives them a more agreeable taste and enables them to yield more of their constituents to water. The coffee thus acquires a chestnut-brown color and loses about 18 per cent. of its weight. The generation of gaseous compounds ruptures the cells, and a peculiar and agreeable aroma is produced, probably largely through decomposition of the fat and tannin. But Payen's (as well as Rochleder's) investigations failed to point out the principles to which the changes are due. Very probably they depend in part upon the decomposition of several of the organic compounds, and unquestionably upon the production of a pyrogenated volatile oil. Caffeine does not partake of these changes except that it is slowly volatilized at the temperature stated; hence the roasting of coffee ought to be effected in closed vessels. Bernheimer (1880) found nearly one-half of the products of roasting

to consist of palmitic acid, the remainder being acetic acid, carbon dioxide, probably acetone, hydroquinone, pyrrol, methylamine, 0.18 to 0.28 per cent. caffeine, and 0.04 or 0.05 per cent. of *coffeol* ("coffeone," $C_8H_{10}O_2$), to which he considered the aroma of coffee to be due. Coffeol is an oil boiling at 195° C. (383° F.), and is probably a methyl ether of saligenin.

Varieties.—The commercial varieties of coffee are very numerous indeed, but of little interest from a pharmaceutical standpoint. For culinary purposes, their selection depends upon both the amount of caffeine and the flavor, chiefly the latter, and blending of different varieties is largely resorted to for securing the desired combination of the two properties. It is almost a rule that one variety will not excel in both of these particulars. From a pharmaceutical standpoint, however, the caffeine content is considered almost alone. In this particular, the Java coffee perhaps takes precedence. Dragendorff determined the following percentages in a number of leading varieties:

	Per cent. of caffeine.		Per cent. of caffeine.
Brown Panang	0.71	First Native Ceylon	0.87
Finest Mocha	0.64	Second Native Ceylon	1.54
Yellow Menado	1.22	Third Native Ceylon	1.59
Finest Plantation Jamaica	1.43	Costa Rica	1.18
Pearl Plantation Ceylon	0.78	West Indian	1.22
First Surinam	1.78	Rio	1.14
Yellow Java	0.88	Jamaica	0.67
Gray Java	2.21	Santos	1.46

Warnier, in 1900, examined 9 samples of Java coffee and found the percentage of caffeine to range between 1 and 1.48. With these he contrasted Liberian coffee, and found it to contain when raw 1.59 per cent., when roasted 2.19 per cent. It is not likely that the roasted coffee actually contained such an excess, but that it was rendered more readily extractable by the changes in roasting. All results agree in according to the Mocha variety a very low percentage of caffeine, although its flavor is probably the most highly esteemed of all.

Maragogipa coffee is a kind very similar, apparently, to the Liberian, if not a form of it.

Adulterants.—In the entire condition, that in which the pharmacist will be likely to handle the drug, the presence of artificial seeds, made by moulding various pastes, has been frequently recorded. These have been detected by placing them in ether. Those which sink are usually spurious, and this fact can be determined by finding the membranous covering absent along the groove of the seed. Aside from sophistication, recourse is had upon a great scale to "doctoring" one variety so as to sell it under the name of another, especially of the Java, which is sought for its high caffeine percentage. A false color and surface are imparted by many ingenious methods of treatment. It has been claimed that some highly poisonous substances, especially arsenic, are used for this purpose, but investigation seems to show that this report was originated by interested parties and is without foundation. Sugar has been considerably used during the roasting process for the purpose of retaining the aromatic oil upon which the flavor depends. An addition of sugar amounting to 1 per cent. of the weight of the green seed is sufficient for this purpose, but very much larger quantities have frequently been employed as an adulterant. An excess of sugar may be detected by shaking the seeds in cold water. The natural sugar does not discolor the water, but that used as an adulterant promptly causes a deep coloration. The difficulty of controlling the amount of the sugar-admixture has led to the use for this purpose of an extract from the fresh pulp of the coffee berry, made at the point of production. Besides retaining the aroma, this develops aromatic products of its own in roasting, probably from the caffeo-tannic acid, these products being very similar to those of the roasted seed. Egg-albumin is used upon an enormous scale to give a beautiful glossy surface to the coffee seeds.

So many adulterants have been used in the case of ground coffee that it is impossible to discuss fully the subject here. Foremost among the substances so used is chicory, sometimes dandelion. Although it was originally introduced as an adulterant, many coffee-drinkers have become attached to the flavor imparted by chicory, and this admixture has now come to be a semi-legitimate trade procedure. F. M. Rimmington (1880) suggests the following process for the detection of these adulterations: The coffee is boiled with water and a little sodium carbonate, then washed with water and macerated

in a weak solution of chlorinated lime for 2 or 3 hours, when the ground coffee will form a dark stratum and the ground chicory a nearly white layer.

Next in degree of importance, perhaps, is the use of beans. Acorns have been largely employed. Since all such substances contain starch, the iodine test will indicate their presence. During recent years various coffee substances made from cereal grains have been introduced for the special benefit of those persons who desire a warm flavored drink, but object to the effects of caffeine upon the nervous system and upon the digestion. Doubtless these substances have found their way to a greater or less extent into ground coffee as an adulterant. Innumerable other substances have been used for the same purpose.

Pharmaceutical Preparations.—Fluidextract of Green Coffee, N. F.; Fluidextract of Roasted Coffee, N. F.; Syrup of Coffee, N. F

Action and Uses.—It is hardly necessary to point out that caffea is consumed in enormous quantities in the form of an infusion or decoction all over the world. Its large consumption depends upon its pleasant taste when it is roasted, which taste is due largely to an empyreumatic oil, and to the fact that the caffeine which it contains acts as a general stimulant. Taken in overdose, caffea, or its active principle caffeine, is capable of acting as a powerful nervous stimulant, increasing the reflexes and the mental activity, but not usually the depth of thought, Its influence upon the kidneys in medicinal or overdose is diuretic. When taken for a long period of time, it often produces indisposition and acidity of the stomach, due to hypersecretion of gastric juice. In other persons it tends to produce biliousness, and in still others palpitation of the heart and tremors. Very large poisonous doses are capable of producing marked increase of the reflexes, cramps in the extremities, staggering gait, and convulsions of a tetanic character. Such severe symptoms, however, practically never follow the use of coffee as a beverage.

Coffee, or its alkaloid caffeine, may be employed as a stimulant in collapse and in opium-poisoning, since it powerfully affects the respiratory center, which is depressed by the opium. By stimulating the intellectual centers in the brain, it also keeps the patient awake, and thereby does not allow him to "forget to breathe." So, too, coffee may be employed as a powerful stimulant in cases of collapse complicating serious operations and injuries, and if it cannot be swallowed, should be given as hot as possible by the rectum.

In France caffeine is very largely employed as a stimulant to the heart in cases of circulatory failure, but in England and America it has not gained great popularity for this purpose. A portion of the increased rapidity of the heart and strength of the pulse under its influence is probably dependent more upon its effects on the nervous system than directly upon the circulatory apparatus. It is one of the few powerful direct diuretics that we have in that it increases urinary flow not only by stimulating the circulation, and so increasing the supply of blood to the kidney, but it also stimulates the secreting epithelium of the uriniferous tubules, and so increases the amount of solids eliminated in the urine. Its employment as a stimulant to the heart is not to be resorted to for long periods of time. It is rather a remedy which is to be used to bridge over a crisis.

The dose of caffeine, or of citrated caffeine, which is more soluble, is from 1 to 5 grains (0.05–0.30 Gm.) 3 times a day. When large doses are repeatedly given, patients not infrequently develop what is known as caffeine insanity, owing to its stimulating effect upon the nervous system, and probably by causing increased activity of the kidneys. This may be prevented to some extent by the simultaneous administration of one of the bromides. As caffeine is insoluble in water, it cannot readily be given hypodermically. Tanret has suggested the following mixture for hypodermic use: Sodium benzoate, 56 grains (3.6 Gm.); caffeine, 48 grains (3 Gm.); distilled water, sufficient to make 2½ drachms (10 Cc.). Each Cc. of this mixture contains 0.3 Gm., or about 5 grains of caffeine.

An additional purpose for which caffeine is employed is the relief of neuralgic headache or that dependent upon eye-strain, in which conditions it does good by stimulating the nervous system. For these conditions it is usually combined with some of the bromides, and often with acetanilid, phenacetin, or antipyrine. There can be no doubt that in this combination it forms one of the most valuable remedies we have for ordinary neuralgic headache.

Coffee Substitutes.—The most important substitutes are the cereal coffees above referred to. Coffee leaves have also been proposed, and are to some extent in native use, since they contain 0.5 per cent. or more of caffeine. Their flavor is, however, very inferior. The membranous covering (*putamen*) of the raw coffee contains nearly 1 per cent. of caffeine, and has been sold as *Sultan* or *Succa* coffee. The pulp of the berry (*sarcocarp*) develops an agreeable flavor, and a method might be found for utilizing it in an admixture with coffee, but it is practically devoid of caffeine, hence not serviceable as a substitute.

Tea, cola, guarana, maté, and related products containing caffeine, will be found treated under these headings. Chocolate is considered under Oleum Theobromatis.

A number of coffee substitutes have been produced which contain no caffeine or related substance. Among these are the following:

The roasted, flattish, ovate seeds of *Cassia occidentalis* L. are used in the tropics as a substitute for coffee under the name of *Negro coffee* or *Mogdad coffee*, and have been met with as an adulterant in Europe; they are best detected by the microscope.

Mussaenda coffee is believed to proceed from *Gærtnera vaginata* Lam. (Fam. *Loganiaceæ*).

Soudan coffee is the seeds of *Parkia Roxburghii* D. Don. The pulp in which they are imbedded in the pod is edible, like that of figs

CAFFEINA, *U. S.*, *Br.*—Caffeine.

Coffeinum, P. G.; *Caffeia, Theine, Guaranine, Trimethyl-xanthine, Methyl-theobromine*, E.; *Caféine, Théine*, Fr.; *Koffeïn, Kaffeïn, Theïn*, G.

Formula, $C_8H_{10}N_4O_2 + H_2O$ or $C_5H(CH_3)_3N_4O_2 + H_2O$. Molecular weight, 210.64.

A feebly basic, proximate principle, obtained from the dried leaves of *Thea sinensis* L. (Fam. *Ternstræmiaceæ*), or from the dried seeds of *Coffea arabica* L. (Fam. *Rubiaceæ*), and found also in other plants or prepared synthetically.—U. S.

An alkaloid usually obtained from the dried leaves of *Camellia Thea* Link, or the dried seeds of *Coffea arabica* L. Crystallized from aqueous solution, it contains 1 molecule of water.—Br.

Preparation.—Caffeine was discovered independently by Runge, Pelletier and Caventou, and Robiquet, in 1821, as a constituent of coffee, and by Oudry, in 1827, as the alkaloid in tea. The pharmacopœias allow its preparation from either coffee or tea, but commercially it is prepared almost exclusively from tea and tea dust or sweepings. From coffee or tea it may be prepared by making a strong decoction of the same, treating it with lead acetate to remove tannic acid and other principles, then removing the excess of lead from the filtrate by hydrogen sulphide, concentrating and crystallizing. The mother-liquor may be treated with animal charcoal to decolorize it, and on concentration will yield an additional crop of crystals of caffeine. Good coffee yields between 0.8 and 2 per cent.; coffee leaves, 0.3 per cent.; maté or Paraguay tea, 0.5 to 2 per cent.; Japan and Chinese teas, 1.5 to 3.5 per cent.; kola-nuts, 1 to 2.3 per cent.; and guarana, about 5 per cent. of caffeine. Synthetically it has been prepared from *guanine*, $C_5H_5N_5O$, and also by heating the theobromine silver compound with methyl iodide in sealed tubes to 160° C. (320° F.) for about 20 hours.

Properties.—Caffeine occurs in white, flexible, silky, glistening needles, usually matted together in fleecy masses, permanent in the air, odorless, and having a bitter taste. If crystallized from water, it contains one molecule of water of crystallization, but if crystallized from alcohol, chloroform, or ether, it contains none. It is soluble at 25° C. (77° F.) in 45.6 parts of water, 53.2 parts of alcohol, 375 parts of ether, and 8 parts of chloroform. Its solubility in water is increased by the presence of certain salts, as, for instance, potassium bromide, sodium benzoate, sodium salicylate, and others. It is also soluble in 5.2 parts of water at 80° C. (176° F.) and in 17.1 parts of alcohol at 60° C. (140° F.). Caffeine sublimes at about 178° C. (352.4° F.), and should leave no residue. Its melting-point is 236.8° C. (458.3° F.).—U. S. The Brit. and Germ. pharmacopœias give the solubility of caffeine as 1 part in 80 parts of cold water, the latter authority also stating that it is soluble in 50 parts of cold alcohol, in 9 parts of chloroform, and in 2 parts of boiling water. Benzene, chloroform, or amyl alcohol, when repeatedly agitated with its solution in acidulated water, dissolves the whole of the caffeine (Dragendorff). Crystallized from alcohol or ether, it is anhydrous; crystallized from water it contains 8.5 per cent. (1 molecule) of water, with which it parts slowly on long exposure to air, or rapidly at temperatures above 100° C. (212° F.). Heated above 100° C. (212° F.) it begins to volatilize, and is completely sublimable at 180° C. (356° F.); it melts to a clear liquid at 230.5 C. (447° F.), and when ignited

burns with a sooty flame leaving no residue (P. G.). The anhydrous crystals have the composition $C_8H_{10}N_4O_2$, and contain 28.8 per cent. of nitrogen. Caffeine, moistened with strong nitric acid or dissolved in chlorine-water and evaporated at the heat of a water-bath, leaves a reddish-yellow residue, which becomes purple by ammonia from the formation of *murexoin* (Schwarzenbach). If a small quantity of caffeine is dissolved in about 1 Cc. of hydrochloric acid, a little potassium chlorate added, the whole evaporated to dryness on a water-bath, and the capsule then inverted over a vessel containing a few drops of ammonia-water, the residue will acquire a rich purple color, which is destroyed by alkalies. It should dissolve in sulphuric or nitric acid without producing a color (absence of organic impurities) and its aqueous solution should not be precipitated by mercuric potassium iodide test-solution (absence of other alkaloids). —U. S. Concentrated aqueous solutions of caffeine give with silver nitrate a white granular, crystalline precipitate; with mercuric chloride, long needles soluble in hydrochloric acid; with palladium chloride, yellow scales; with picric acid, no precipitate; the alkaloid dissolves in sulphuric and in nitric acid, and the solution remains colorless for several hours (Dragendorff). On adding to a solution of a small quantity of caffeine in concentrated sulphuric acid a minute fragment of potassium dichromate, it will acquire a yellowish-green color, which gradually becomes green.—U. S. Lloyd (1881) and Biedermann (1882) showed that caffeine salts with organic acids may be obtained from chloroform, and that they are easily decomposed by water. Tanret (1882) regards the solutions of caffeine in sodium benzoate, cinnamate, and salicylate as definite compounds suitable for hypodermic use; these solutions may be made so as to contain in each Cc. (15 minims) 0.20 Gm. (3 grains) of caffeine, and with sodium salicylate 0.30 Gm. (4½ grains). The salts with mineral acids have an acid reaction to test-paper, and are decomposed by water or alcohol. Their concentrated solutions yield with mercuric-potassium iodide a precipitate which soon crystallizes in needles. Similar precipitates obtained with other alkaloids remain amorphous (Delffs, 1854). Diluted acidulated solutions of caffeine are not precipitated by mercuric-potassium iodide (Mayer's test); but in aqueous solution containing a large excess of mineral acid caffeine is precipitated with quantitative accuracy by solution of iodine in potassium iodide (Wagner's reagent) as $C_8H_{10}N_4O_2.HI.I_4$, in which 1 part of iodine represents 0.3834 part of caffeine, or 1 Cc. decinormal iodine solution is equal to 0.00485 Gm. of caffeine. Under different conditions of precipitation it forms various haloid combinations, a thorough *résumé* of which is detailed by Gomberg (*Jour. Am. Chem. Soc.*, 18, pp. 347–377).

When caffeine is heated with solutions of fixed alkali hydroxides, it is decomposed, water being assimilated, methylamine and ammonia given off, and *caffeidine-carboxylic acid*, $C_8H_{12}N_4O_3$, formed, which on further heating with fixed alkali hydroxide may be changed to the strong uncrystallizable base caffeidine, $C_7H_{12}N_4O$ (Strecker, 1861), which is easily soluble in water and alcohol, and but sparingly soluble in ether. The decomposition takes place mainly according to the equation $C_8H_{10}N_4O_2 + H_2O = C_7H_{12}N_4O + CO_2$. O. Schultzen (1867) and F. Rosengarten (1871) proved that by prolonged boiling a further decomposition takes place, affecting chiefly the caffeidine, and resulting in the production of sarkosine, formic acid, methylamine, and ammonia; thus, $C_8H_{10}N_4O_2 + 6H_2O = C_3H_7NO_2 + CH_2O_2 + 2CH_3H_2N + NH_3 + 2CO_2$.

A cold saturated aqueous solution of caffeine should not be rendered turbid on the addition of solution of chlorine or iodine, nor discolored on the addition of water of ammonia (P. G.). 0.1 Gm. of caffeine added to 1 Cc. of either sulphuric or nitric acid should dissolve without discoloration (P. G.). In an aqueous solution of caffeine tannic acid gives a white precipitate soluble in excess of the reagent (Br., P. G.).

Pharmaceutical Preparation.—Elixir of Caffeine, N. F.

Action and Uses.—The physiological effects and therapeutic uses of this remedy are discussed under Caffea.

CAFFEINE COMPOUNDS.

The hydrochloride, hydrobromide, and nitrate of caffeine may be prepared by dissolving the caffeine in the respective acid, setting the solution aside over quicklime for spontaneous evaporation, and collecting the resulting crystals on blotting-paper for final drying.

Caffeinæ Hydrobromidum. *Coffeinum hydrobromicum. Caffeine hydrobromide, Koffeinhydrobromat, Bromwasserstoffsaures Koffein.* $C_8H_{10}N_4O_2.HBr + 2H_2O$. Molecular weight, 308.88. Contains 62.4 per cent. of caffeine.—Colorless transparent crystals readily decomposed by treatment with alcohol or water. It is somewhat more stable than the hydrochloride, but

loses its hydrobromic acid when dried at 110° C. (230° F.). It is used for nervous headache.

Caffeinæ Hydrochloridum. *Coffeinum hydrochloricum. Caffeine hydrochloride, Koffeinhydrochlorat, Salzsaures Koffein.* $C_8H_{10}N_4O_2.HCl + 2H_2O$. Molecular weight, 264.70.—Caffeine hydrochloride contains 72.8 per cent. of caffeine and crystallizes in large colorless monoclinic prismatic needles. It is readily decomposed into its constituents by washing with alcohol or water, and loses water of crystallization and acid on long exposure to air, the crystals becoming opaque. Dried at 100° to 110° C. (212° to 230° F.) all the chlorine may be volatilized, leaving pure caffeine.

Caffeinæ Nitras. *Coffeinum nitricum. Caffeine nitrate, Koffeinnitrat, Salpetersaures Koffein.* $C_8H_{10}N_4O_2.HNO_3 + H_2O$. Molecular weight, 273.21.—Crystallize in small thick prisms, readily decomposed by water and alcohol, loses all the nitric acid when dried at 100° C. (212° F.), and contains about 70.5 per cent. caffein.

Caffeinæ Phenylas. *Coffeinum phenylicum. Caffeine phenol, Koffein-phenol, Coffeo-phenol.* $C_8H_{10}N_4O_2.C_6H_6O + H_2O$. Molecular weight, 303.98.—A white or faint reddish crystalline mass, soluble in water, and obtained by dissolving 22.6 parts of caffeine in 10 parts of fused carbolic acid.

Caffeinæ Sulphas. *Coffeinum sulfuricum. Caffeine sulphate, Koffeinsulphat, Schwefelsaures Koffein.* $C_8H_{10}N_4O_2.H_2SO_4$. Molecular weight, 290.11. Contains 66.4 per cent. of caffeine.—To prepare the sulphate, caffeine is dissolved in about 10 times its weight of alcohol containing more than the proper equivalent of sulphuric acid, and set aside to crystallize. The crystals are decomposed by water and alcohol, but may be recrystallized from alcohol containing sulphuric acid.

Æthoxycaffeina, *Æthoxycoffeinum. Ethoxycaffeine,* E.; *Æthoxy-Koffein,* G. $C_8H_9(OC_2H_5)N_4O_2$. Molecular weight, 236.46.—Prepared by adding caffeine to an excess of bromine and then boiling the resulting bromide with an alcoholic solution of potassium hydroxide; or according to Thoms by adding to an alcoholic solution of monobromcaffeine gradually, and in small pieces, an equivalent of metallic sodium sufficient to take up the bromine, and then boiling the solution and concentrating it to crystallize. Colorless needles, difficultly soluble in cold water, readily soluble in alcohol, and melting at 138°–139° C. (280.4°–282.2° F.). Distinguished from caffeine by being precipitated when sodium hydroxide is added to an aqueous (1 per cent.) solution of the æthoxycaffeine, the solution of caffeine remaining clear.

CAFFEINA CITRATA, *U. S.*—Citrated Caffeine.

Caffeinæ Citras, Br.; *Caffeine citrate,* E.; *Citrate de Caféine* Fr.; *Koffëincitrat, Citronensaures Koffein,* G.

An unstable compound, $C_8H_{10}N_4O_2,C_6H_8O_7$, prepared from caffeine and citric acid.—Br.

Molecular weight, 382.38. Contains 50.25 per cent. of anhydrous caffeine and 49.75 per cent. of anhydrous citric acid.

Preparation.—Caffeine, 50 Gm.; citric acid, 50 Gm.; distilled water, hot, 100 Cc. Dissolve the citric acid in the hot distilled water, add the caffeine, and evaporate the resulting solution on a water-bath to dryness, constantly stirring toward the end of the operation. Reduce the product to a fine powder and transfer it to well-closed bottles.—U. S. The process of the British Pharmacopœia is identical with the above. It also is readily prepared by mixing an alcoholic solution of citric acid with a chloroform solution of caffeine and evaporating the mixture.

Citrated caffeine is a white odorless powder having a slightly bitter, acid taste, and an acid reaction. One part of citrated caffeine forms a clear, syrupy solution with about 4 parts of hot water. Upon dilution with 5 parts of water, a white crystalline precipitate (caffeine) separates, which redissolves when about 25 parts of water have been added. It is soluble also in a mixture of equal volumes of chloroform and alcohol.—U. S.

Lime water added to a 1 per cent. aqueous solution of citrated caffeine should produce no turbidity, but should cause a precipitate on boiling the solution, the precipitate disappearing after the solution has cooled (test for citric acid). Citrated caffeine should give the caffeine reaction with chlorine as mentioned under Caffeine. It should not discolor when dissolved in either sulphuric or nitric acid; leave no residue when burned; give no turbidity with barium nitrate, silver nitrate, or potassium oxalate, nor a discoloration with hydrogen sulphide (absence of sulphate, chloride, lime, and lead).

If 1 gram of caffeine citrate be dissolved in 20 Cc. of boiling water, the solution made alkaline with excess of solution of sodium hydroxide, and after cooling extracted successively with 15, 10, and 10 Cc. of chloroform, the combined chloroform extracts when evaporated and dried at 100° C. (212° F.) should weigh 0.5 Gm. (Hager).

Action and Uses.—Citrated caffeine may be employed for the same purposes as caffeine. For its mode of administration and dose, see CAFFEA.

CAFFEINA CITRATA EFFERVESCENS, *U. S.*—Effervescent Citrated Caffeine.

Caffeinæ Citras Effervescens, Br.; *Coffeinum citricum effervescens. Effervescent caffeine citrate*, E.; *Brausendes Koffeincitrat*, G.

Preparation.—Citrated caffeine, 40 Gm.; sodium bicarbonate, dried and powdered, 570 Gm.; tartaric acid, dried and powdered, 300 Gm.; citric acid, uneffloresced crystals, 195 Gm., to make about 1000 Gm. Powder the citric acid and mix it intimately with the citrated caffeine and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4°–219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6, tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2 F.).—U. S.

The Br. P. directs that a mixture of sodium bicarbonate, 51 Gm., and refined sugar, 14 Gm., be thoroughly incorporated with a previously prepared mixture of caffeine citrate, 4 Gm., tartaric acid, 27 Gm., and citric acid, 18 Gm., and the whole then placed in a dish or pan heated to between 93.3° and 104.4° C. (200° and 220° F.). When the mixture has assumed a granular character, it is passed through sieves of suitable size. The product dried at a temperature of 54.4° C. (130° F.) should weigh 100 Gm.

Action and Uses.—This remedy is merely an agreeable form of administering the alkaloid. Its uses and effects are identical with those of caffeine. The dose is 1 drachm (4 Gm.) in a half glass of cold water, taken during effervescence.

CAFFEINÆ SODIO-SALICYLAS.—Caffeine Sodio-salicylate.

Coffeino-Natrium salicylicum, P. G.; *Koffein-Natriumsalicylat*, G.

Preparation.—Caffeine, 50 Gm.; sodium salicylate, 50 Gm.; alcohol, a sufficient quantity. Triturate the caffeine with the sodium salicylate and a sufficient quantity of alcohol to a smooth paste, and dry this by exposure in a moderately warm place. Rub the dry mass to powder, and keep it in well-stoppered bottles.

The P. G. directs that 50 parts of caffeine and 60 parts of sodium salicylate be dissolved in 200 parts of water, and the solution evaporated to dryness.

Properties.—Caffeine sodio-salicylate occurs both as a white amorphous powder and as white granules, odorless, of a sweetish-bitter taste, and soluble in twice their weight of water; also soluble in 50 parts of alcohol. If heated in a test-tube, white vapors, having the odor of carbolic acid, will be developed. An aqueous 20 per cent. solution should be colorless when freshly made, and develop at most a faint pink color and faint acid reaction after standing a few hours. The addition of ferric chloride solution causes a bluish-violet coloration even in very dilute aqueous solution, which serves to distinguish caffeine sodio-salicylate from the sodio-benzoate, the latter causing a brown precipitate.

Tests.—An aqueous 5 per cent. solution should not be affected by hydrogen sulphide nor by barium nitrate solution; and if 2 volumes of the same be mixed with 3 volumes of alcohol and then acidulated with nitric acid, the mixture should not be affected by silver nitrate solution. 0.1 Gm. of caffeine sodio-salicylate should dissolve in 1 Cc. of sulphuric acid without effervescence and without color. If 0.5 Gm. of the salt be boiled with successive portions of 5 Cc. of chloroform, the united clear solutions should yield on evaporation at least 0.2 Gm. of dry caffeine.—P. G.

This preparation is used as a diuretic (see THEOBROMINE).

Allied Preparations.—CAFFEINÆ SODIO-BENZOAS; COFFEINO-NATRIUM BENZOICUM. *Caffeine sodio-benzoate*, E.; *Koffein-Natriumbenzoat*, G.—The Swiss Pharmacopœia directs that 50 parts of caffeine and 59 parts of sodium benzoate shall be dissolved in 200 parts of water, the solution evaporated to dryness, and the residue reduced to powder. The proportions given by the National Formulary are very similar, being 50 parts each of caffeine and sodium benzoate, to be made into a smooth paste with sufficient alcohol, and then dried by exposure in a moderately warm place. Caffeine sodio-benzoate is a colorless amorphous powder, having a bitter, aromatic taste, and soluble in 2 parts of water.

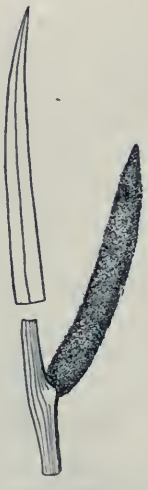
CAFFEINÆ SODIO-CINNAMAS; COFFEINO-NATRIUM CINNAMYLICUM. *Caffeine sodio-cinnamate*, E.; *Koffein-Natriumcinnamat*, G.—This compound may be made in the same manner as the preceding, using sodium cinnamate in place of the benzoate. It is a white amorphous powder, soluble in 2 parts of water and about 30 parts of alcohol.

CALAMUS, *U. S.*—Calamus.

Radix Calami Aromatici, Radix Acori; Rhizoma Calami (P. G.), *Sweet flag* (*Sweet sedge, cane, rush, root, or myrtle*), *Myrtle-flag* (*-grass or -sedge*), E.; *Kalmus or Kalmuswurzel*, G.; *Acore vrai* (Cod.), *Acore odorant*, Fr.; *Acorro verro*, It.; *Calamo aromatico*, It., Sp.

The dried unpeeled rhizome of *Acorus Calamus* L. (Fam. *Araceæ*).

Fig. 68.



Calamus: inflorescence and part of leaf (½ Nat.).

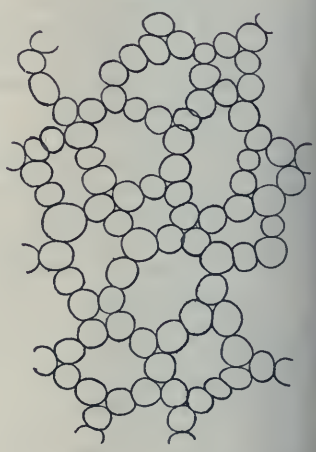
Fig. 69.

Upper and lower surface of rhizome (¾ Nat.).

Official in most pharmacopœias. The German defines it as peeled.

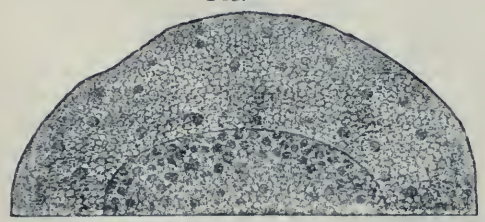
Origin.—A herbaceous perennial bog-plant, about a yard high, the stem, leaf, and inflorescence here illustrated. It grows wild in abundance over a large part of the north temperate zone. It inhabits muddy swamps and is highly gregarious, the rhizome branching and extending most widely. All parts of the plant are aromatic. The young and tender inflorescence is eaten by children, and a sort of confection was formerly extensively used, made by "candying" the surfaces of transverse slices of the fresh rhizome, and constituted a popular form of its medicinal use.

Fig. 71.



Calamus texture, greatly magnified.

Fig. 70.



Transverse section of rhizome of calamus; magnified 3 diameters.

Description.—In entire or split pieces of indefinite length and 1 to 2 Cm. (⅖ to ⅘ In.) thick; when entire, cylindraceous and somewhat flattened from above downward, occasionally exhibiting a short stump of a lateral branch; externally yellowish-brown with blackish patches,

sharply longitudinally wrinkled, the upper surface obliquely marked with broad, dark, often fibrous leaf-scars which are often broadly V-shaped, and have sharply projecting margins, the lower surface thickly pitted with root-scars which exhibit a low whitish rim and a dark depressed center; fracture short, sharp, corky, whitish, starchy, the texture spongy, exhibiting numerous oil-cells and scattered wood-bundles, the latter crowded just within, and scattered outside of the endodermis; odor strongly aromatic; taste strongly aromatic, pungent, and bitter.

The handsome, white, peeled ("German") calamus of the market cannot be used in accordance with the official requirements. This, when fresh, is white, but turns pinkish on drying, and is less aromatic and bitter than the unpeeled. The agreeable aromatic odor is best preserved by keeping the rhizome unpeeled, as directed by the Pharmacopœia. Calamus should, it is said, be collected early in the spring, and deprived of the far less aromatic and bitter roots, which are 10 to 15 Cm. (4 to 6 In.) long, unbranched, but near the tip beset with soft thin fibers. On drying, calamus loses from 70 to 75 per cent. in weight.

Constituents.—The official rhizome yields 1.5 to 3.5 per cent. of a pale-yellow volatile oil having the odor and sharp taste of calamus, choline (formerly thought to be a specific alkaloid, *calamine*), soft resin, gum, starch, and the glucoside *acorin* ($C_{36}H_{60}O_6$). This last is amorphous, semifluid, resinous, of neutral reaction, aromatic odor, and bitter, aromatic taste. It is insoluble in water, but soluble in ether, chloroform, and absolute alcohol. In a current of hydrogen, it may be split into sugar and oil of calamus, but acted upon in the presence of air it oxidizes to *acoretin*, a neutral resin, which, however, by reduction in alkaline solution, yields the volatile oil and sugar.

The fresh rhizome yields 0.8 per cent. of volatile oil, 2.3 per cent. of soft resin, 5.5 per cent. of gum, and 1.6 per cent. of starch.

Pharmaceutical Preparation.—Fluidextract of Calamus, U. S. P.

Action and Uses.—Calamus is not largely employed in medicine at the present time, but may be given as a mild aromatic stimulant and tonic. It was formerly used in the treatment of flatulent colic and atonic dyspepsia, and was supposed to be beneficial as a mild stimulant in typhoid states.

The dried root may be chewed *ad libitum* to relieve dyspepsia, or an infusion made with 1 ounce (30 Gm.) of the drug and 1 pint (480 Cc.) of water may be given in doses of from 1 to 2 fluidounces (30–60 Cc.).

CALCII BROMIDUM, *U. S.*—Calcium Bromide.

Calcium bromatum.—*Bromure de calcium*, Fr.; *Bromcalcium, Calciumbromid*, G.

Formula, $CaBr_2$. Molecular weight, 198.52.

It should contain not less than 97 per cent. of pure calcium bromide and should be kept in well-stoppered bottles.—U. S.

Preparation.—Calcium bromide is readily prepared by dissolving pure calcium carbonate in hydrobromic acid until effervescence ceases, filtering to remove any excess of undissolved carbonate, and evaporating to dryness.

Properties.—Thus obtained, calcium bromide is a whitish, granular or pulverulent, neutral, very deliquescent salt, having a pungent, bitter and saline taste. It is freely soluble in alcohol (1 part, U. S.) and water, the latter solution yielding with difficulty colorless needles. It dissolves in 0.5 part of water at 25° C. (77° F.). The aqueous solution is neutral to litmus.

The salt melts at a red heat, giving off bromine; treated with strong sulphuric acid, hydrobromic acid is evolved, afterward bromine and sulphur dioxide. The aqueous solution yields with ammonium oxalate a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid (calcium oxalate); with silver nitrate, a curdy precipitate insoluble in nitric acid and in diluted ammonia water (silver bromide); and with a few drops of chlorine water liberates bromine, which dissolves in carbon disulphide with a yellow or brown-yellow color free from violet tint. The solution left in contact with lime forms calcium oxybromide, which has a strong alkaline reaction, and on evaporation is left as a very white salt.

Tests.—The neutral reaction of the salt and its ready solubility in water and alcohol exclude most impurities. If to 5 Cc. of a 5 per cent. aqueous solution, slightly acidu-

lated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, neither coloration nor turbidity should be perceptible after the tube has stood corked at 35° C. (95° F.) for at least half an hour, either before or after rendering alkaline with ammonia-water (absence of heavy metals). 1 Gm. of the salt in 20 Cc. of water should form a clear, colorless solution, free from residue (absence of insoluble impurities). If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color (absence of bromate). If to 10 Cc. of a 5 per cent. solution of the salt 1 Cc. of chloroform be added, then chlorine-water diluted with an equal volume of water, drop by drop, with constant shaking, the liberated bromine dissolved in the chloroform should have a yellow to orange color free from any violet (absence of iodine). If 1 Gm. of the salt and 1 Gm. of sodium acetate be dissolved in 5 Cc. of distilled water and made slightly acid with dilute acetic acid, after boiling and cooling, the solution should not become cloudy within 5 minutes after shaking with 5 drops of potassium dichromate test-solution (absence of barium). If 5 Cc. of a 1 per cent. solution of the salt, 5 Cc. of potassium hydroxide test-solution, and about 0.2 Gm. of aluminum wire be placed in a tube, in the upper portion of which is then inserted a plug of purified cotton and over the mouth a piece of wet red litmus-paper, and the tube be heated in boiling water for 15 minutes, no blue coloration of the paper should be discernible (limit of nitrates and ammonia).—U. S.

Pharmaceutical Preparation.—Elixir of Calcium Bromide, N. F.

Action and Uses.—Calcium bromide may be employed for the same purposes as its corresponding potassium salt (see Potassii Bromidum). It was introduced into medicine in 1871, by Dr. Hammond, as a remedy for hysteria, insomnia, and epilepsy, but it has no distinct advantage over the potassium salt, except that the calcium base is not so depressant to the heart as the potassium. The dose is from 20 to 60 grains (1.30–4 Gm.), best administered in syrup or elixir.

CALCII CARBONAS PRÆCIPITATUS, *U. S., Br.*—Precipitated Calcium Carbonate.

Calcium carbonicum præcipitatum, P. G.; *Calcaria carbonica præcipitata, Creta præcipitata.—Precipitated carbonate of lime, Precipitated chalk*, E.; *Carbonate de chaux précipité, Craie précipitée*, Fr.; *Calciumkarbonat. Präcipitirter kohlensaurer Kalk*, G.; *Carbonato di calcio precipitato*, It.; *Carbonato de cal*, Sp.

Formula, $CaCO_3$. Molecular weight, 99.35.

It should contain not less than 99 per cent. of pure calcium carbonate.—U. S.

Preparation.—It is obtained by adding to a hot solution of pure calcium chloride, while stirring, a solution of ammonium carbonate until an alkaline reaction is obtained. Ammonium chloride and a precipitate of calcium carbonate are formed. The latter is washed by decantation and on the filter with boiling water until silver nitrate gives no test for chlorine in the filtrate. It is then dried at 100° C. (212° F.). If calcium carbonate is precipitated in the cold, it is flocculent and quite voluminous, and with difficulty deprived of the mother-liquor by washing; hence it is advisable to heat the solutions before mixing them.

Properties.—Thus prepared, it is a white, impalpable, inodorous, tasteless powder consisting of microscopic rhombohedric crystals, but entirely free from grittiness. It has the specific gravity 2.72, is without action upon moistened test-paper, and is not altered in the air, but above 400° C. (752° F.) begins to evolve carbon dioxide, and at a red heat is entirely converted into calcium oxide. The salt is nearly insoluble in water; the solubility is increased by presence of ammonium salts, and especially by carbonic acid; alkali hydroxides diminish it. It is insoluble in alcohol, but dissolves without residue in dilute hydrochloric, nitric, or acetic acid, carbon dioxide being copiously given off.—U. S.

Tests.—For applying tests of identity and purity, 5 Gm. are mixed with 100 Cc. of pure water, followed by hydrochloric acid, drop by drop, while stirring, until solution takes place. The solution, after boiling and cooling, should be of acid reaction and free from more than a trace of insoluble matter. A portion of this solution, neutralized with ammonia-water, yields with ammonium oxalate test-solution a white precipitate of calcium

oxalate, insoluble in acetic but soluble in hydrochloric acid. In 20 Cc. of the solution rendered alkaline with ammonia-water, no turbidity or precipitate should be produced either before or after boiling (absence of iron, alumina, phosphates, etc.). If to 5 Cc. of the solution 5 drops of hydrochloric acid and 1 Cc. of potassium sulphate test-solution be added, no turbidity should result (absence of barium). 10 Cc. of the solution, mixed with 1 Cc. of diluted hydrochloric acid and 10 Cc. of fresh hydrogen sulphide test-solution, should not produce a color or turbidity when kept corked at 35° C. (95° F.) for at least half an hour, either before or after rendering slightly alkaline with ammonia-water (absence of heavy metals). If 1 Gm. of the salt be agitated with 50 Cc. of water, the filtrate should not show an alkaline reaction with litmus-paper, and, on evaporation, should not leave more than a trace of fixed residue (limit of soluble impurities).—U. S.

A substitution of calcium sulphate for the carbonate, wholly or partly, has been occasionally observed; this will not readily dissolve in diluted hydrochloric acid. Boiled with distilled water and allowed to cool and then filtered, a liquid will be obtained giving a white precipitate with barium chloride.

Action and Uses.—This remedy is employed for the same purpose as prepared chalk (see CRETA PRÆPARATA).

CALCII CHLORIDUM, *U. S.*, *Br.*—Calcium Chloride.

Calcium chloratum.—Chlorure de calcium, Fr.; *Chlorcalcium, Calciumchlorid*, G.; *Cloruro di calcio*, It., Sp.

Formula, $CaCl_2$. Molecular weight, 110.16.

Calcium chloride deprived of its water by fusion at the lowest possible temperature. It should be preserved in a well-stoppered bottle, and should contain not less than 99 per cent. of pure calcium chloride.—U. S.

Preparation.—This compound is a by-product in many chemical processes, among others that for solution of ammonia. It may be formed by neutralizing hydrochloric acid with marble or other calcium carbonate: $CaCO_3 + 2HCl$ yields $CaCl_2 + CO_2 + H_2O$. Iron being usually contained in these native carbonates, it is removed by digesting the solution with chlorinated lime and slaked lime, by which the iron is first converted into ferric chloride and then precipitated as ferric hydroxide. The filtrate, which will be found to have an alkaline reaction, is neutralized with hydrochloric acid, evaporated, and the residue fused at the lowest temperature. The Br. P. directs that the salt be heated at a temperature not above 200° C. (392° F.), whereby the salt $CaCl_2 + 2H_2O$ is obtained.

Properties.—Calcium chloride is in white, dry, but very deliquescent inodorous masses, and has a hot, saline, bitterish, sharp taste. When the salt is overheated in fusing, a small quantity of chlorine is expelled as hydrochloric acid; hence the anhydrous salt usually has a faint alkaline reaction, which is increased at a red heat. It is soluble at 25° C. (77° F.) in 1.3 parts of water with production of heat, and in 8 parts of alcohol; soluble in 1.5 parts of boiling alcohol, insoluble in ether, chloroform, fatty and ethereal oils, etc. A saturated aqueous solution at 15° C. (59° F.) has the specific gravity 1.41104. Alcoholic solutions, when evaporated to crystallization, yield compounds containing alcohol of crystallization, as $CaCl_2 + 4C_2H_6O$ and $CaCl_2 + 4CH_4O$; hence the chloride cannot be used as a drying agent for alcohol. It is unsuitable for drying ammonia gas, since it forms with the latter a compound, $CaCl_2 + 4NH_3$. On cooling a concentrated aqueous solution, crystals of the composition $CaCl_2 + 6H_2O$ are formed, which melt at about 30° C. (86° F.). The salt containing 2 molecules of water, when mixed with two-thirds of its weight of snow or finely crushed ice, produces a temperature of —45° C. (—49° F.). From an aqueous solution, insoluble white calcium oxalate is precipitated by adding ammonium oxalate solution. The precipitate is insoluble in acetic, but soluble in hydrochloric acid. The chlorine present is detected by silver nitrate solution in the usual way.

Tests.—The aqueous solution (1 in 20) should remain clear upon addition of ammonia-water, even after boiling (absence of iron, aluminum, etc.), or of barium chloride test-solution (absence of sulphate). If from 100 Cc. of the solution the calcium be completely precipitated by ammonium oxalate test-solution, the filtrate should, on evaporation, leave not more than a trace of fixed residue (limit of magnesium and alkalies). If 10 Cc. of the aqueous solution, acidulated with hydrochloric acid, be mixed with an equal volume

of hydrogen sulphide test-solution, neither color nor turbidity should appear after standing corked at 35° C. (95° F.) for at least half an hour, either before or after addition of ammonia-water (absence of arsenic, lead, etc.). If to 5 Cc. of the solution (1 in 20) 5 drops of hydrochloric acid and 1 Cc. of potassium sulphate test-solution be added, no turbidity should result (absence of barium).—U. S.

Action and Uses.—Overdoses of calcium chloride produce severe gastro-intestinal inflammation, which may be followed by death if the amount is sufficiently great. In moderate doses it frequently causes gastric irritability, and for this reason its employment often has to be discontinued. The drug has been given with varying success in the treatment of scrofulous enlargements of the superficial lymphatic glands, of lupus, and of scrofulous caries. Its employment is sometimes of service in those cases where insufficient bone-formation exists, and also after fractures. The drug has also been used for the purpose of increasing the coagulability of the blood in purpura, hæmophilia, and other hemorrhages. In these conditions it should be given in large doses for a period not longer than 4 days, as its secondary effect is to decrease the coagulability of the blood. Its administration has been recommended a few days prior to surgical operations upon the gall-bladder for the purpose of preventing the continual oozing of blood which sometimes occurs when marked jaundice is present. It is said to prevent urticaria and pruritus by some influence on the blood-plasma. A solution of the drug has been employed in poultices for the purpose of hastening the suppuration of boils.

The internal dose of calcium chloride is from 5 to 30 grains (0.30–2 Gm.), best administered in one full dose followed at frequent intervals by a smaller one. The liquor calcii chloridi (U. S. P., 1870) contains 228 grains of the salt in 1 ounce of distilled water, and may be given in doses of from 10 to 40 minims (0.6–2.6 Cc.).

CALCII GLYCEROPHOSPHAS.—Calcium Glycerophosphate.

Calcium glycerino-phosphoricum.—*Glycerino-phosphate de chaux*, Fr.; *Calcium glycerinophosphat*, G.

Formula, $C_3H_5(OH)_2CaPO_4 + H_2O$. Molecular weight, 226.46.

Preparation.—This is obtained by neutralizing a solution of glycerophosphoric acid with milk of lime or calcium carbonate, filtering off the calcium phosphate, and concentrating the filtrate in a vacuum. The calcium salt is then precipitated by addition of alcohol, filtered, and washed with alcohol. To purify the salt, this treatment is repeated.

Properties.—It is a white crystalline powder, soluble in 20 parts of water, but less soluble in hot water; neutral to litmus, but the commercial product is sometimes acid. The salt loses its water of crystallization at or above 130° C. (266° F.).

Tests.—The salt should be free from ordinary phosphoric acid, which would yield a precipitate with magnesia mixture or ammonium molybdate solution; in the latter case, heat must be avoided, since a solution of the salt is decomposed by heat into phosphoric acid and glycerin. A solution of the salt should not give a precipitate with excess of ammonium molybdate on long standing, indicating the absence of free glycerophosphoric acid, which slowly decomposes in solution. Adhering glycerin is detected by shaking the salt with absolute alcohol and evaporating the filtrate. Hydrogen sulphide should give no precipitate when passed into a solution of the salt (absence of heavy metals), nor barium chloride (absence of sulphate); and silver nitrate should cause only a slight opalescence. These tests also apply to the corresponding potassium, sodium, and lithium salts, and, in addition, the latter should give no precipitate with dilute sulphuric acid (absence of barium).

Action and Uses.—This preparation is regarded as an excellent tonic and nervine, and as an efficient substitute for the other calcium salts used for these purposes. It has been given in the treatment of diabetes mellitus for the double purpose of furnishing phosphates to the system and of supplying the calcium which is eliminated in excess by the urine in this disease. In the treatment of neurasthenia it has recently acquired considerable reputation. It has also been proposed as a remedy for incontinence of urine.

The dose for an adult is from 5 to 10 grains (0.30–0.60 Gm.); for a child, from 4 to 6 grains (0.25–0.40 Gm.), according to the age, twice daily.

CALCII HYPOPHOSPHIS, *U. S.*, *Br.*—Calcium Hypophosphite.

Calcium hypophosphorosum. Hypophosphite of lime, E.; *Hypophosphite de chaux*, Fr.; *Calciumhypophosphit, Unterphosphorigsaurer Kalk*, G.

Formula, $Ca(H_2PO_2)_2$. Molecular weight, 168.86.

It should contain not less than 98 per cent. of pure calcium hypophosphite, and should be kept in well-stoppered bottles; caution should be taken in dispensing the salt, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.—U. S.

Preparation.—This salt is formed when milk of lime and phosphorus are heated together in a deep vessel, the chief products being calcium hypophosphite and inflammable hydrogen phosphide; thus, $3Ca(OH)_2 + 8P + 6H_2O = 3Ca(H_2PO_2)_2 + 2PH_3$. When the phosphorus has disappeared, the mixture is filtered, evaporated to dryness on a water-bath or allowed to crystallize when strongly concentrated. Nearly half the phosphorus is oxidized to phosphoric acid, probably by the decomposition of water, since the escaping gas contains free hydrogen (Wurtz), and remains with the excess of lime as calcium phosphate. E. Scheffer (1858) succeeded in avoiding much of this loss by using phosphorus which had been partially oxidized under water by passing atmospheric air into it, whereby the phosphorus assumes a spongy appearance and unites with the lime even at the ordinary temperature, but more readily at 55° C. (about 130° F.), very little spontaneously inflammable gas being generated. The salt is prepared on the large scale by adding granulated phosphorus to milk of lime and exposing the mixture to the air, and agitating frequently until the phosphorus has disappeared. A small portion of hydrogen phosphide is evolved (Gmelin-Kraut's *Chemie*). It is well to precipitate the dissolved lime by passing carbon dioxide through the warm filtrate and by filtering again.

Hypophosphites, when boiled in aqueous solution with alkali, are decomposed into phosphite or phosphate and hydrogen.

Properties.—Calcium hypophosphite crystallizes in transparent, thin, flexible scales composed of flat monoclinic prisms, but is usually met with as a white crystalline powder with a pearly lustre, of neutral or slightly acid reaction, inodorous, and of a bitter, nauseous taste. In the dry state it is permanent in the air, but when dissolved in water it is gradually oxidized to calcium phosphate. Heated to redness in a retort, it decrepitates, evolves water, spontaneously inflammable hydrogen phosphide, and a little phosphorus, and leaves nearly 80 per cent. of a reddish residue containing a little amorphous phosphorus and calcium pyrophosphate. The salt dissolves in 6.5 parts of water at 25° C. (77° F.) and in 6 parts of boiling water; it is insoluble in strong and but slightly soluble in dilute alcohol (H. Rose). The solution yields white precipitates with silver nitrate and with mercuric chloride, both turning dark when heated, from reduction to the metallic state. Metallic gold is precipitated from the chloride, and the soluble copper salts yield with the solution, particularly on heating, metallic copper. Ammonium oxalate produces in the solution a white precipitate which is insoluble in acetic acid, but dissolves in hydrochloric acid.

Tests.—If 1 Gm. of the salt be dissolved in 20 Cc. of water, not more than a trace of insoluble residue should be left (absence of phosphate, sulphate, and other insoluble impurities). In this solution no precipitate should be produced by the addition of lead acetate test-solution (absence of soluble phosphate and phosphite, Br.). If 5 Cc. of the solution (1 in 10) be mixed with 10 Cc. of water and 3 Cc. of nitric acid in a beaker, and the whole evaporated to dryness on a water-bath, the residue should not respond to the modified Gutzeit s test for arsenic (given under ARSENI TRIOXIDUM). The object of the nitric acid is to oxidize the salt to calcium acid phosphate, on which the nascent hydrogen in the test has no action. 10 Cc. of the solution of the salt (1 in 20), acidulated with hydrochloric acid, should yield no color or turbidity when mixed with an equal volume of fresh hydrogen sulphide solution and kept corked at 35° C. (95° F.) for at least half an hour, either before or after making alkaline with ammonia-water (absence of heavy metals).—U. S. The assay method by tenth-normal potassium permanganate given in the U. S. P., 1890, has been dropped, and no method is now official. On boiling 0.25 Gm. of the salt for 10 minutes with a solution of 0.6 Gm. of potassium permanganate, a nearly colorless filtrate should be obtained.—Br.

H. A. D. Jowett (*Pharm. Jour.*, 1898) has critically examined the former method of analysis and the properties of pure and commercial hypophosphites, and comes to the

conclusion that the permanganate method is defective in itself, and also is not applicable, because the commercial hypophosphites usually contain as impurity some phosphite, which reacts with the permanganate. This is detected by lead acetate, giving an insoluble precipitate, which is attributed, in U. S., 1890, to the presence of soluble phosphate, but the latter, according to Jowett, is an unlikely impurity. The Br. test with lead acetate requires that no precipitate be produced, whereas it is only rarely that commercial specimens are free from phosphite, which, hence, would give a precipitate of lead phosphite.

Jowett's method of assay, which seems to be accurate, consists in removing impurities by solution of lead acetate, precipitating excess of lead and the calcium from the filtrate by addition of sulphuric acid and alcohol, filtering, and oxidizing the hypophosphorous acid in the filtrate by bromine, or, better, by potassium chlorate and hydrochloric acid to phosphoric acid, which is then determined gravimetrically or volumetrically in the usual way. Jowett gives the solubility of pure calcium hypophosphite as 1 in 6.43 parts of water at 20° C. (68° F.), while that of the commercial specimens was found variable.

Pharmaceutical Preparations.—Elixir of Calcium Hypophosphite, N. F.; Syrup of Calcium Hypophosphite, N. F.; Syrup of Hypophosphites, U. S.

Action and Uses.—Calcium hypophosphite is probably converted into a phosphate in the stomach and absorbed as a lactophosphate. It does not possess the property of stimulating or regenerating nervous matter and other tissues containing phosphorus, and has a physiological action wholly different from the latter substance. Because of the calcium base it has been given with asserted success in the treatment of rachitis, mollities ossium, in fractures where union is sluggish, in dental caries (particularly in nursing women), and in scrofula and incipient tuberculosis. The drug is practically of no value in the later stages of phthisis, except that it may to a certain extent combat the accompanying anæmia.

The dose of this salt is from 10 to 30 grains (0.60–2 Gm.) 3 times daily. It is commonly prescribed in the form of a syrup.

CALCII PHOSPHAS PRÆCIPITATUS, *U. S.*—Precipitated Calcium Phosphate.

Calcii phosphas, Br.; *Calcium phosphoricum*, P. G.; *Calcaria phosphorica—Precipitated phosphate of lime*, E.; *Phosphate de chaux hydraté*, Fr.; *Calciumphosphat. Phosphorsaure Kalkerde*, G.

Formula, $Ca_3(PO_4)_2$. Molecular weight, 307.98.

It should contain not less than 99 per cent. of pure di- and tricalcium phosphate.—U. S.

Preparation.—The U. S. gives no method of preparation, while the Br. gives only an outline, thus: Bone ash (calcined bone) is dissolved in moderately dilute hydrochloric acid, forming acid calcium phosphate, $Ca(H_2PO_4)_2$, and calcium chloride, $CaCl_2$, in solution, which is then poured into dilute ammonia water in sufficient quantity to leave an alkaline reaction. A precipitate of tricalcium phosphate is formed; thus, $Ca(H_2PO_4)_2 + 2CaCl_2 + 4NH_4OH = Ca_3(PO_4)_2 + 4NH_4Cl + 4H_2O$. When formed in cold solution, the precipitate is at first amorphous and voluminous, and difficult to wash, but on stirring a long time it becomes crystalline. The precipitate is washed on the filter with hot water until the filtrate no longer gives a precipitate with silver nitrate acidified with nitric acid and then dried at 100° C. (212° F.).

The calcium phosphate of the German Pharmacopœia is prepared by precipitating a solution of calcium chloride with sodium phosphate, has the composition $CaHPO_4 \cdot 2H_2O$, is more readily soluble than the above salt, and when heated to redness loses 26 per cent. of water. The percentage of water in this salt varies with the temperature of precipitation and the length of time that the precipitate remains in contact with the solution.

Occasionally commercial calcium phosphate is contaminated with ammonium chloride, due to imperfect washing.

Properties and Tests.—This preparation is often called *bone phosphate*, to dis-

tinguish it from other calcium phosphates: it forms a light, white, amorphous, permanent powder, which at an intense white heat fuses without decomposition, and on cooling yields a porcelain-like mass. When fused with sodium carbonate or digested with a solution of this salt, it is partly decomposed, with the formation of calcium carbonate. It is almost insoluble in water; almost insoluble in acetic acid, except when freshly precipitated, but somewhat soluble in solutions of sodium chloride and other neutral alkali salts. Continued boiling with water induces decomposition, with the formation of basic phosphate, $Ca_5(PO_4)_3OH$, and of hydrophosphate, $CaHPO_4$. When moistened with silver nitrate test-solution, a yellow color (silver phosphate) is assumed by the salt either before or after ignition (distinction from acid calcium phosphate, which, after ignition, remains white when moistened with silver nitrate, $CaHPO_4$ forming the pyrophosphate, $Ca_2P_2O_7$, and $Ca(H_2PO_4)_2$ the metaphosphate, $Ca(PO_3)_2$, on ignition, neither of which gives a yellow color with silver nitrate). For applying tests of identity and purity, shake 2 Gm. of the salt with 20 Cc. of water, and add nitric acid, drop by drop, until solution is effected; then add water to make the liquid measure 40 Cc. No effervescence should occur on adding the acid (absence of carbonate). From a portion of this solution the salt is precipitated unchanged by a slight excess of ammonia water. From another portion ammonium molybdate test-solution precipitates yellow ammonium phosphomolybdate; the reaction is accelerated by gentle heat. If to 5 Cc. of the solution, acidulated with nitric acid, 0.5 Cc. of silver nitrate test-solution be added, not more than a slight turbidity should result (limit of chloride). If to 5 Cc. of the solution, strongly acidulated with nitric acid, 1 Cc. of potassium sulphate test-solution be added, no turbidity should result upon standing (absence of barium). If 5 Gm. of the salt be boiled with about 20 Cc. of sodium hydroxide test-solution and filtered, and to the filtrate, acidulated with hydrochloric acid, there be added a few drops of ferrous sulphate test-solution, and again boiled, no blue precipitate or coloration should result (absence of cyanides). 10 Cc. of a solution of the salt (1 in 20), obtained by shaking the salt with water and adding hydrochloric acid, drop by drop, to slight excess and heating, should not be colored or made turbid by an equal volume of hydrogen sulphide solution when kept corked at 35° C. (95° F.) for at least half an hour, either before or after making alkaline with ammonia-water (absence of heavy metals). 2 Gm. of the salt should not respond to the modified Gutzeit's test for arsenic (given under ARSENI TRIOXIDUM).—U. S.

The Br. demands that 1 Gm. of the salt, dissolved in hydrochloric acid, reprecipitated by ammonia water, washed and dried at 100° C. (212° F.), should give not less than 0.95 Gm. weight.

The salt of the P. G., when calcined, should lose 25 to 26 per cent. of its weight.

Pharmaceutical Preparations.—ELIXIR OF CALCIUM LACTOPHOSPHATE, N. F.; SYRUP OF CALCIUM LACTOPHOSPHATE, U. S. P.; SYRUP OF CALCIUM LACTOPHOSPHATE WITH IRON, N. F.; SYRUP OF CALCIUM CHLORHYDROPHOSPHATE, N. F.

Action and Uses.—Precipitated calcium phosphate may be employed for the same purposes and in the same doses as calcium hypophosphite (which see). In the form of Syrupus Calcii Lactophosphatis it is said to be more readily assimilable than is the latter salt, and for this reason is considered the better preparation. The dose of the syrup is 1 fluidrachm (4 Cc.).

CALCII SULPHAS EXSICCATUS, *U. S.*—Dried Calcium Sulphate.

Calcium sulfuricum ustum, P. G.; *Dried gypsum, Plaster of Paris*, E.; *Plâtre cuit*, Fr.; *Gebrannter Gyps*, G.

A powder containing about 95 per cent. of calcium sulphate ($CaSO_4$; molecular weight, 135.15) and about 5 per cent. of water.—U. S.

Preparation.—Native calcium sulphate is carefully heated until about three-fourths of its water has been expelled.—U. S.

It should be preserved in well-closed vessels, to prevent gradual absorption of moisture from the atmosphere.

Properties.—Dried gypsum occurs as an amorphous white powder, without taste or odor, and when mixed with half its weight of water it forms a smooth paste which rapidly hardens. It is soluble at 25° C. (77° F.) in about 378 parts of water, at

35° C. (95° F.) in 370 parts, and at 100° C. (212° F.) in 451 parts. It is insoluble in alcohol, but dissolves readily in diluted nitric or hydrochloric acid, also in saturated solutions of potassium nitrate, sodium thiosulphate, and of various ammonium salts. Heated to above 204° C. (399.2° F.), dried gypsum becomes anhydrous, and loses the property of forming a paste with water and hardening rapidly. Its saturated solution in water should be neutral to litmus-paper, and forms a white precipitate with alcohol and with solutions of ammonium oxalate (calcium) and of barium chloride (sulphuric acid). The addition of diluted acids to dried gypsum should not cause effervescence (absence of carbonate).—U. S.

Action and Uses.—Plaster-of-paris is never employed in internal medicine. It is used in surgery for immobilizing injured or diseased portions of the body. Gauze bandages, the meshes of which are filled with this substance, are immersed in water, or preferably in a weak solution of sodium chloride, and then applied evenly and firmly over the injured part which has first been bandaged with canton flannel. In the course of 10 or 15 minutes this hardens and forms a firm cast over the part. This dressing is especially applicable to tubercular disease of the hip-, knee-, or ankle-joints, gonorrhœal rheumatism, injuries or diseases of the spine, and fractures of the long bones. By some it is employed to hold the dressing after operative procedures; for instance, amputation of the breast and Pirogoff's amputation. In dental surgery it is extensively employed for making moulds for interdental splints and other forms of apparatus.

Calcii Sulphas.—*Native calcium sulphate, Gypsum,* E.; *Sulfate de chaux,* Fr.; *Calciumsulfat, Schwefelsaurer Kalk, Gyps,* G. $CaSO_4 + 2H_2O$. Molecular weight, 170.91.—This compound is met with in nature in the form of transparent prisms known as *selenite,* and in semi-opaque masses which are called *alabaster* and *gypsum.* The same compound is precipitated on adding sulphuric acid or a sulphate to a solution of a calcium salt. It is a white crystalline powder, insoluble in alcohol. Its solubility in water is about the same as for dried gypsum. Another form of calcium sulphate, containing no water of crystallization, occurs in nature, and is called *anhydrite.*

CALCIUM.—Calcium.

Calcium, Fr., G. Symbol, Ca. Valence, 2. Atomic weight, 39.8.

Calcium is an element belonging to the so-called *alkaline earth* metals, which consist of calcium, strontium, and barium. These 3 metals form a natural group, in which there is a gradation of properties. The atomic weights increase from calcium to barium, and the valence is bivalent for all 3 metals. The chlorides, hydroxides, and nitrates are soluble in water; the sulphates decrease in solubility as the atomic weights increase, while the reverse is true in the case of the hydroxides. Unlike the alkali metals, they are more permanent in air, harder and heavier, decompose water only slowly at ordinary temperature to form difficultly soluble hydroxides, and form insoluble phosphates and carbonates (the bicarbonates are soluble). Moreover, the sulphates, chromates, borates, fluorides, and silicofluorides of the alkali earth metals are insoluble or difficultly soluble in water.

Calcium occurs in enormous quantities in nature, chiefly in the form of carbonate, as limestone, marble, and chalk; also as sulphate or gypsum, as phosphate or apatite and phosphorite, and as fluoride or fluorspar. It is found in most mineral waters as carbonate or sulphate, and in plants and animals. Bones contain a large quantity of calcium phosphate; coral and shells of eggs and molluscs contain calcium carbonate. Next to aluminum and iron, calcium forms the greatest proportion of the solid crust of the earth.

Calcium was first prepared by Bunsen by electrolysis of molten calcium chloride. Moissan prepared it pure by heating metallic sodium and calcium iodide to a high temperature in a closed vessel. On cooling, small compact crystals of calcium separated from the excess of sodium, which were isolated by alcohol, which dissolved the sodium.

Pure calcium is silver-white (Moissan), and not yellow as formerly described, has a metallic luster, the hardness of calcspar, and a specific gravity of 1.554 at 18° C. (64.4° F.). It melts at red heat and burns violently in the air; is readily soluble in dilute mineral acids, but is not acted on by concentrated nitric acid.

Calcium salts are colorless unless the acid be colored, have a neutral reaction upon

test-paper, and impart to the flame of the blowpipe a yellowish-red color. Calcium salts soluble in water are not precipitated by ammonia, but yield white precipitates with ammonium carbonate, phosphate, and oxalate, and with sulphuric acid, the latter precipitate being soluble in a large quantity of water, and the former ones in acetic acid, with the exception of the oxalate. Those salts which are insoluble in water are dissolved by dilute hydrochloric acid, and this solution is not disturbed (that of calcium oxalate excepted) when solution of sodium acetate is added in excess; but if to this liquid a solution of ammonium oxalate is added, all the calcium will be precipitated as calcium oxalate.

Calcii Carbidum.—*Calcium carbide*, E.; *Calciumkarbid, Gasstein*, G. CaC_2. Molecular weight, 63.62

Carbides are compounds of carbon with the elements, particularly the metals. The manufacture of these and their industrial application became possible when the electric furnace was devised, whereby temperatures between 3500° and 4000° C. (6332° and 7232° F.) could be obtained. The essential feature of this furnace is the intense heat of a flame produced by a powerful current passing between two carbon electrodes, in an enclosure of some difficultly fusible substance, as magnesia or graphite. Calcium carbide has attained great commercial value, because it is the source of acetylene gas, which is now coming into general use for lighting purposes (see Acetylenum). It is the most important of all the carbides, and is prepared by heating a mixture of 120 parts of freshly heated lime and 80 parts of carbon (coal, coke, or carbon from sugar) between the carbon electrodes of a furnace which is supplied with a current of 350 ampères and 70 volts. The yield is 120–150 parts. The reaction is $CaO + 3C = CO + CaC_2$. The present commercial variety contains about 20 per cent. of impurities. An article of good quality presents relatively heavy crystalline, brownish-red masses. Chemically pure carbide is colorless and transparent (Moissan). It gives off, when exposed to the air, a garlic odor, due to hydrogen phosphide, and is gradually converted into hydroxide and carbonate of calcium. Its most characteristic and valuable property is its behavior when in contact with water, whereby acetylene gas is formed: $CaC_2 + 2H_2O = Ca(OH)_2 + C_2H_2$ (acetylene). 1 kilogram of pure carbide yields 350 liters of acetylene, while the commercial product yields only 280–300 liters.

Wöhler obtained calcium carbide in 1862; but it was Willson, at Spray, North Carolina, and Moissan, at Paris, who perfected the present method of obtaining it by the electric furnace.

Action and Uses.—For the therapeutic effects of this remedy, see Acetylenum.

OTHER CALCIUM SALTS.

Calcii Acetas.—*Calcium acetate*, E.; *Acétate de chaux*, Fr.; *Essigsaurer Kalk*, G. $Ca(C_2H_3O_2)_2.H_2O$.—The pure salt may be obtained by neutralizing 4 parts of 30 per cent. acetic acid with 1 part of precipitated calcium carbonate and evaporating to crystallization. The salt forms colorless shining needles, less soluble in alcohol than water. It dissolves lead sulphate.

Calcii Benzoas.—*Calcium benzoate*, E.; *Benzoate de chaux*, Fr.; *Benzoësaures Calcium*, G. $Ca(C_7H_5O_2)_2.4H_2O$.—Obtained by heating 43 parts of benzoic acid with 10 parts of calcium oxide in water, filtering, and crystallizing. The benzoic acid in the filtrate may be recovered by acidifying. The salt forms colorless efflorescent crystals, soluble in 20 parts of cold water. Like sodium benzoate and sodium salicylate, it is used as an internal antiseptic.

Calcii Beta-naphtol Sulphonas.—*Calcium beta-naphtol sulphonate*, E.; *Beta-Naphtolsulfosaures Calcium*, G.; *Abrastol, Asaprol.* $[C_{10}H_6(OH)SO_3]_2Ca + 3H_2O$.—A white to slightly reddish neutral powder, soluble in 1.5 parts of water or in 3 parts of alcohol. The aqueous solutions give a blue color with solution of ferric chloride. Used in preserving foods and as an intestinal antiseptic—dose 15 to 30 grains (1–2 Gm.). Also given for rheumatism, gout, typhus, and neuralgia, in daily doses of 15–60 grains (1–4 Gm.).

Calcii Boras, *Calcium tetraboricum.*—*Calcium borate*, E.; *Calciumborat*, G. $CaB_4O_7 + 6H_2O$.—This may be obtained by mixing a solution of 10 parts of crystallized calcium chloride in 100 parts of water with a solution of 17.4 parts of crystallized borax in 100 parts of water, filtering, and washing the precipitate. It is a white tasteless powder, alkaline to litmus, insoluble in cold water, soluble in glycerin with acid reaction. It is used as an antiseptic for moist eczema, burns, etc., and internally for diarrhœa of children; dose 3 to 6 grains (0.2–0.4 Gm.).

Calcii Iodas.—*Calcium iodate*, E.; *Iodate de chaux*, Fr.; *Jodsaurer Kalk*, G. $Ca(IO_3)_2.6H_2O$.—This salt may be prepared by mixing slowly an alcoholic solution of iodine with an excess of a filtered aqueous solution of bleaching-powder, and avoiding rise of temperature to prevent the formation of iodine chloride. Iodine is oxidized to iodic acid, which forms calcium iodate as a precipitate. Calcium iodate crystallizes from water in flat, colorless, shining needles, which are slowly efflorescent on exposure, require at 15° C. (59° F.) about 300 parts of water for solution, and are nearly insoluble in alcohol. The aqueous solution yields a white precipitate with ammonium oxalate, and liberates iodine on the addition of sulphurous acid. Calcium iodate has been advanced as an antiseptic and antipyretic, but it is rarely employed in medicine. It has been recommended, however, for the preservation of food-products.

Calcii Iodidum, *Calcium iodatum.*—*Calcium iodide*, E.; *Iodure de calcium*, Fr.; *Calciumjodid, Jodcalcium*, G. CaI_2.—This may be prepared by neutralizing a solution of hydriodic acid with calcium carbonate, filtering, evaporating to dryness, and fusing. It forms white deliquescent crystalline masses or pearly crystals of bitter taste. Exposed to the air or moisture, it turns yellow, due to decomposition and liberation of iodine. It is freely soluble in alcohol and water, and is very deliquescent. A syrup of calcium iodide is used in medicine (see under Syrups). Calcium iodide has been employed by M. Malem in the treatment of pulmonary tuberculosis, and is preferred by him to all the other iodides. It has never met with general favor among practitioners. The dose for internal administration is from 1 to 4 grains (0.05–0.25 Gm.), largely diluted. The latter amount, however, causes considerable irritation, but this may be due to the fact that liberated iodine is present.

Calcii Lactas.—*Calcium lactate*, E.; *Lactate de chaux purifié*, Fr. Cod.; *Calciumlactat, Milchsaurer Kalk*, G. $Ca(C_3H_5O_3)_2 + 5H_2O$.—Large quantities of this compound are obtained incidentally as an intermediate product in the preparation of lactic acid. It is desirable, however, in making small quantities, to start with pure calcium carbonate and pure lactic acid. A hot dilute solution of the acid is neutralized with the carbonate, filtered, and set aside to crystallize. The salt forms white warty, crystalline masses, having no odor and scarcely any taste, and soluble in 9.5 parts of cold water and much less hot water, difficultly soluble in cold alcohol. It becomes anhydrous at 100° C. (212° F.). Containing calcium in an absorbable form, it is used in rachitis and scrofula, in the dose of from 3 to 10 grains (0.2–0.6 Gm.), and mostly combined with calcium carbonate or phosphate, or iron lactate. It is given most often as syrup of calcium lactophosphate.

Calcii Permanganas.—*Calcium permanganate.* $Ca(MnO_4)_2.5H_2O$.—A compound crystallizing like the potassium salt and very soluble in water. Recommended in the purification of drinking-water and as an antiseptic in gastro-enteritis and diarrhœa, in doses of ½ to 1½ grains (0.025–0.075 Gm.). Also to cleanse cavities in the teeth.

Calcii Salicylas.—*Calcium salicylate*, E.; *Salicylsaures Calcium*, G. $[C_6H_4(OH)CO_2]_2Ca + 2H_2O$.—A hot 10 per cent. solution of salicylic acid is neutralized with iron-free calcium carbonate, filtered, and evaporated to crystallization. The salt forms a white, odorless, tasteless crystalline powder, almost insoluble in cold water. Used in gastro-enteritis in doses of 8 to 20 grains (0.5–1.3 Gm.).

Calcii Sulphis, *Calcium sulphurosum.*—*Calcium sulphite*, E.; *Schwefligsaurer Kalk*, G. $CaSO_3 + 2H_2O$.—4 parts of slaked lime are intimately mixed with 1 part of water; the mixture is spread in thin layers, and sulphur dioxide passed into the vessel or chamber as long as it is absorbed; or the gas is passed into milk of lime and the resulting precipitate dried. Calcium sulphite is a white powder requiring 800 parts of cold water for solution; it dissolves readily in aqueous sulphurous acid, and crystallizes from this solution in hexagonal prisms. It has a slight sulphurous taste, and on exposure is gradually converted into calcium sulphate. It is used as an antifermentative in beer and wines. Calcium sulphite has no advantage over its analogous potassium and sodium compounds. It has been employed for the purpose of limiting fermentation and putrefaction. Being a rather unstable compound, its acid radical is easily eliminated, and advantage has been taken of the fact in its local employment for the treatment of parasitic skin diseases; for example, ringworm, tinea, scabies, pityriasis versicolor, and thrush. It may also be used in the treatment of fermentative dyspepsia, but other more potent remedies are commonly employed.

Calcii Sulphocarbolas seu Sulphophenas.—*Calcium sulphocarbolate or sulphophenate*, E.; *Karbolsulfosaures Calcium*, G. $[C_6H_4(OH)SO_3]_2Ca + H_2O$.—Obtained by neutralizing para-phenolsulphonic acid with calcium carbonate. A colorless, nearly odorless, astringent, bitter powder, easily soluble in water and alcohol. Used as antiseptic, disinfectant, and astringent, internally, in doses of 1 tablespoonful of a 1 per cent. solution every 3 hours.

Calcii Thiosulphas seu Hyposulphis.—*Calcium thiosulphate or hyposulphite.* $CaS_2O_3 + 6H_2O$.—This salt occurs in large colorless hexagonal prisms, soluble in an equal weight of water. On heating this solution above 60° C. (140° F.), calcium sulphite and sulphur are formed. The salt should be protected against air and light.

CALENDULA, *U. S.*—Calendula.

Marigold, Mary-bud, Holigold, E.; *Ringelblume, Todtenblume, Warsenkraut*, G.; *Souci, Fleur de tous les mois*, Fr.

The dried ligulate florets of *Calendula officinalis* L. (Fam. *Compositæ*).

Origin.—A stout, somewhat rough-hairy annual of southern Europe and adjacent Asia, with alternate thickish leaves, the lower obovate, the upper successively narrower, entire, or serrate with few teeth, the heads solitary at the ends of the slender branches, with a saucer-shaped involucre of about 2 rows of lance-linear scales, a flat, naked receptacle, ligulate rays and tubular disk-florets, both yellow. The former only are fertile, their akenes being strongly incurved, roughened, blackish, those of the outermost row narrowly winged. Under cultivation, most of the florets become ligulate and these only are collected for the official drug. The plant has a peculiar, strong and heavy odor, largely lost in drying. The entire plant has been largely used in the fresh condition in eclectic and homœopathic medicine, and was official in the Pharmacopœia of 1880.

Description.—Lemon-yellow to orange; about 12 Mm. (½ In.) long, and 3 Mm. (⅛ In.) broad, linear-oblong, flat, with a short, hairy, delicately nerved basal tube, and an immature akene, without pappus, surmounted by a filiform style having 2 rather long branches; odor characteristic, rank; taste bitterish and slightly saline. It sometimes occurs pressed into cakes.

Fig. 72.

Calendula.

A very pale color, after exposure to sunlight, is indicative of defective quality, and such an article is excluded by the above description.

The closely related genus *Tagetes* has furnished 2 much-used substitutes, the florets of *T. erecta* L. and of *T. patula* L., of tropical and subtropical America. They are very similar, and have probably the same or very similar constituents and properties. They are cultivated under the name of *African marigold*. They can be distinguished by their possession of a pappus of several scales.

Constituents.—These are gum, sugar, a trace of volatile oil, an amorphous bitter principle, and *calendulin*, an amorphous, yellow, tasteless, neutral principle, soluble in alcohol and glacial acetic acid, insoluble in ether and oils, forming with water a transparent mucilage, and not precipitated by tannin.

Pharmaceutical Preparations.—Fluidextract of Calendula, N. F.

Action and Uses.—An infusion made from the leaves and flowers of this drug was formerly thought to be stimulant, antispasmodic, and emmenagogue. It was prescribed in the treatment of typhoid states, functional amenorrhœa, jaundice, hepatic congestion, and scrofulosis. It was given both internally and applied externally in the treatment of cancer, but without any marked results. As an embrocation, a tincture made from the flowers was recommended in the treatment of sprains and contusions, but it is probable that its virtues depended upon the menstruum and not upon the drug.

The internal dose of the extract is stated to be from 1 to 3 grains (0.06–0.20 Gm.).

CALLITRICHACEÆ.—The Water-starwort Family.

A family of a single genus, the species being estimated by different authors at from 1 to 25. *Callitriche verna* L., native of stagnant or sluggish waters in Europe and northern North America, and *C. heterophylla* Pursh.; of the southern United States, are used as diuretics. The submerged leaves of both, on the slender filamentous stems, are long and linear, the aërial ones floating in rosettes, those of the first-named species obovate and nearly sessile, those of the second broadly spatulate and petioled. The constituents are entirely unknown. These drugs have been employed in renal dropsy, and were formerly administered by veterinary surgeons to promote diuresis in horses. Callitriche has been employed to some extent in the form of a decoction or tincture in the treatment of dropsy depending upon renal disease.

CALUMBA, *U. S.*—Calumba.

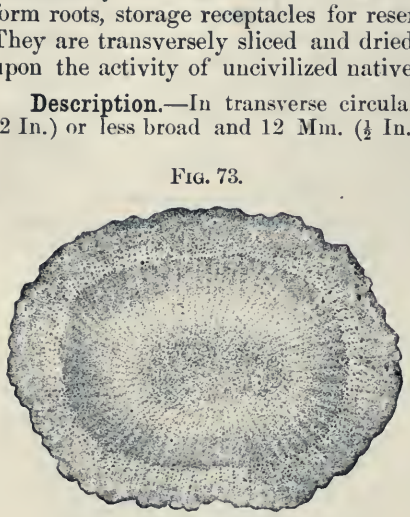
Calumbæ Radix, Br.; *Radix colombo*, P. G.; *Radix columbo. Colombo*, E.; *Colombowurzel*, G.; *Colombe*, Fr., Sp.; *Colombo*, F. It.

The dried root of *Jateorhiza palmata* (Lam.) Miers (*Menispermum p.* Lam., *Cocculus p.* DC.—Fam. *Menispermaceæ*).

Origin.—From a very high-climbing herbaceous twiner of tropical eastern Africa, especially the Zambesi region. It is cultivated to some extent, both there and in the East Indies, for the sake of its root, there called *Kalumb*, and used for dyeing, as well as medicinally. It was introduced to European use by the Portuguese. The fleshy fusiform roots, storage receptacles for reserve-food material, are attached to a stout rhizome. They are transversely sliced and dried. The supply is very irregular, being dependent upon the activity of uncivilized natives, so that the price is subject to wide fluctuations.

Description.—In transverse circular, or oblique oval, biconcave sections, about 5 Cm. (2 In.) or less broad and 12 Mm. (½ In.) or less in thickness at the circumference, less than half as thick at the center, the edge brown, occasionally greenish, roughly wrinkled, the smoothish cut surfaces pale-yellow, becoming darker or brown with age, annular, the yellow, finely radiate cortex separated by a narrow dark line from the lighter inner portion, which is radiate with its only slightly projecting rows of vascular bundles; fracture short, mealy; odor slight; taste very bitter, mucilaginous, slightly aromatic.

Fig. 73.



Calumba: transverse section (Nat.).

Underneath the cork there is an almost continuous layer of stone-cells containing crystals of calcium oxalate, which appear in the powder. The yellow powder is characterized by rather large stone-cells and abundant starch-grains almost as large as those of the potato, varying from circular to oval, or ovate, commonly flattened, the large hilum mostly excentric, entire or strongly fissured in one or more directions, and with a few strong rings.

The Ph. It. calls attention to the fact that calumba colors alcohol intensely, but ether not at all; also that the aqueous maceration does not affect litmus, gelatin, or ferric chloride.

Calumba is much subject to worminess if long kept.

Substitutions.—American calumba (see Frasera) has been frequently sold for this, but is very easily recognized. It is almost uniformly much smaller, the color is not yellow, it contains no starch, and is not mucilaginous. Its decoction is colored brownish with iodine and gives a brown precipitate with ferric chloride. The related root, also the stem, of *Coscinium fenestratum* Coleberooke, of India, has occasionally been substituted, and is largely so used in India. It is a woody root, the disks nearly equally thick at center and circumference. The stem reaches 10 Cm. (4 In.) in diameter, is yellowish-gray, or yellowish-brown by the loss of the cork, longitudinally furrowed and finely transversely fissured. The section is strongly radiate, the fracture tough-splintery.

Under the name *Calumba de Brasil* (or *de Pais*) the woody root of *Simaruba salubris* Engl. is said to be used in Brazil as a substitute for calumba.

Constituents.—The root contains *berberine*, *calumbic acid* ($C_{21}H_{22}O_6$), *calumbin* ($C_{21}H_{24}O_7$) in combination with the alkaloid *calumbine* (?) (Alessandri), and a fluorescent body which makes the infusion look turbid by reflected light; it contains no tannin. The woody portion yields 1.9 per cent. of calumbin and 0.72 per cent. of berberine, the cortex 1.42 per cent. of calumbin and 1.43 per cent. of berberine (Hilger, 1896), the older roots developing more of these principles than the younger ones. Dohme (1897) says the yield of calumbin is 0.4 to 0.8 per cent., and that there is a greater amount of berberin. Calumbin forms colorless, odorless, and very bitter prisms and needles, nearly insoluble in water, but soluble in alcohol, ether, chloroform, alkalies, and acetic acid. Calumbic acid is less bitter, amorphous, straw-yellow, almost insoluble in cold water or ether, and soluble in alcohol and alkalies. The berberine and calumbic acid are believed to be derived from calumbin, of which acid the latter is the anhydride. Other constituents are 35 per cent. of starch, 17 per cent. of pectin, 4.7 per cent. of gum, 5 per cent. of resin, and wax. The ash is about 6 per cent.

Pharmaceutical Preparations.—Fluidextract of Calumba, U. S. P.; Infusion of Calumba, Br. P.; Tincture of Calumba, U. S. P.

Action and Uses.—Calumbin is said, in small doses, to augment the secretion of the liver and the gastro-intestinal glands, but in large doses it acts as an emeto-cathart

(Roux). Kohler stated that its intravenous injection increases blood-pressure by stimulation of the vasomotor center.

Berberine is an hepatic stimulant, and in large amounts produces diarrhœa, and occasionally vomiting and tremors. When injected intravenously or subcutaneously in animals, berberine causes respiratory failure, convulsions, and paralysis of the hind extremities (Cushny).

Colombo may be classed among the simple bitters, and employed with benefit during convalescence from acute infectious fevers and serous diarrhœas. Given before meals, it at first inhibits secretion, but secondarily increases in a marked degree the flow of gastric juice; hence its value in atonic dyspepsia. The drug has also been recommended in the vomiting of pregnancy and in the nausea and vomiting incident to teething. An infusion made with ½ ounce of columbo, ½ ounce of ginger, 1 drachm of senna, 1 pint of boiling water, was highly recommended by Dr. George B. Wood in the treatment of gastro-intestinal disorders when associated with flatulence.

In substance, the dose is from 10 to 30 grains (0.60–2 Gm.), repeated 3 or 4 times a day. The fluidextract may be given in doses of from 15 minims to 1 fluidrachm (1–4 Cc.); the tincture, in doses of from ½ to 2 fluidrachms (2 to 8 Cc.). The dose of the infusion (4 drachms (16 Gm.) to 1 pint (480 Cc.) of water) is ½ to 1 fluidounce (16–30 Cc.).

CALX, *U. S., Br.*—Lime; Calcium Oxide.

Calcaria usta, P. G.; *Calcii oxidum, Calcium oxydatum, Calcaria, Calx viva, Calx usta.—Burned lime*, E.; *Chaux, Chaux vive*, Fr.; *Kalk, Aetzkalk, Gebrannter Kalk*, G.; *Ossido di calcio*, It., Sp.

Formula, CaO. Molecular weight, 55.68.

Lime, prepared by burning white marble or the purest varieties of natural calcium carbonate, and containing, when anhydrous, not less than 90 per cent. of pure calcium oxide. It should be kept in well-closed vessels in a dry place.—U. S.

Preparation.—Lime is an alkaline earth which is obtained by calcining native calcium carbonate, such as chalk, limestone, or marble, by which carbon dioxide is given off, calcium oxide remaining behind: $CaCO_3$ is decomposed into $CO_2 + CaO$. Prepared on the large scale from native carbonates, it contains also the impurities naturally existing therein, such as magnesia, ferric oxide, alkali salts, silica, and clay. If the latter is present in sufficient quantity, it will slake feebly or not at all, and is then called *poor* or *over-burnt*. To obtain pure lime, pure calcium carbonate should be employed, and if the calcining has been done in a crucible the resulting mass should be moistened with water and again calcined to expel the carbon dioxide completely. The same effect is produced on the large scale by constructing the lime-kiln in such a manner that the products of combustion pass over the limestone.

Properties.—Burnt lime is in hard white or grayish-white porous masses, of the specific gravity 3.1 to 3.2. It is fusible with difficulty only before the oxyhydrogen blowpipe, giving off a splendid red light, but is not otherwise altered. It is inodorous, and has an alkaline reaction and a caustic, burning taste. At 25° Cc. (77° F.) it requires about .760 parts of water for solution; but at 100° C. (212° F.) more than 1550 parts are necessary; hence a solution of lime saturated in the cold becomes turbid on being heated. Exposed to the air, it absorbs water and carbon dioxide, and is converted into calcium hydroxide and carbonate, known as *air-slaked* lime.

Slaked lime forms a soft white powder, of specific gravity 2.08 and of strongly alkaline taste and reaction. It does not part with its water at 100° C. (212° F.), and becomes completely anhydrous only at a dull-red heat, without melting previously. On exposure to the air, it is converted into calcium carbonate. When lime is slaked, or slaked lime is mixed with about 3 or 4 parts of water to form a thin magma, the mixture is called *milk of lime*.

Sugar and glycerin greatly increase the solubility of lime in water. Lime decomposes most of the alkali and metallic salts by combining with their acids and forming calcium salts, which are mostly insoluble. Hence it is incompatible with these, as well as with astringent vegetable infusions, alkaloidal salts, and free acids.

Lime is extensively used in the arts, generally in the form of hydroxide. It is used in the preparation of ammonia, potassium and sodium hydroxide, bleaching-powder, and potassium chlorate; also in tanning to remove hair from hides, in saponifying fats, in the purification of illuminating-gas, and in making mortar.

Tests.—If 1 part of lime be slaked, and then thoroughly mixed with 50 parts of water, and the greater portion of the milky liquid decanted, no hard, gritty particles should be found in the residue, nor should the addition of hydrochloric acid to this residue cause much effervescence (limit of carbonate), nor leave more than a slight, insoluble residue. For applying tests, 5 Gm. of the oxide are slaked, mixed with 100 Cc. of water and dissolved with a slight excess of hydrochloric acid, boiled, and cooled. Not more than 0.025 Gm. of insoluble matter should remain. In a portion of this solution neutralized with ammonia-water, ammonium oxalate solution forms a white precipitate of calcium oxalate, insoluble in acetic, but soluble in hydrochloric acid.—U. S.

Pharmaceutical Preparations.—Lime-water, U. S. P.; Syrup of Lime, U. S. P.

Calcii Hydras, Br.; *Calcaria hydrica.—Slaked lime, Calcium hydroxide, Calcium hydrate,* E.; *Chaux éteinte, Chaux hydratée,* Fr.; *Kalkhydrat, Gelöschter Kalk,* G.

Formula, $Ca(OH)_2$. Molecular weight, 73.56.

Calcium hydroxide is official in the Br. It may be prepared by moistening lime with half its weight of water, whereby, if the lime is good, much heat is generated, steam is formed copiously, and the pieces of lime become a dry powder of slaked lime: $CaO + H_2O = Ca(OH)_2$.

Action and Uses.—Lime itself is employed in medicine as an escharotic and disinfectant. When placed upon the skin and moistened, it causes rapid and deep destruction of the tissue. It has been employed in the treatment of indolent ulcers, for the removal of small nævi and of superfluous hairs, but for the latter purpose it is not recommended. An ointment containing 5 per cent. of the drug in benzoinated lard may also be tried in the treatment of favus and psoriasis. As it arrests putrefaction, it has been employed to disinfect feces and urine, cesspools, and various places where odors arise from putrefactive fermentation. Lime taken internally in overdose causes a sensation of burning in the œsophagus and stomach, followed by severe gastro-enteritis. The caustic action of the drug may produce sloughing of the stomach and intestines, followed by perforation with collapse and death. This condition should be treated early by the administration of a vegetable acid, such as vinegar and demulcent drinks. Appropriate stimulation may be given as the case demands.

Lime is never given internally except in solution. For its other therapeutic uses, see Liquor Calcis.

CALX CHLORINATA, *U. S., Br.*—Chlorinated Lime; Chlorinated Calcium Oxide.

Calx chlorata, U. S., 1890; *Calcaria chlorata,* P. G.; *Chloruretum calcis, Calcii hypochloris.—Chloride of lime, Calcium hypochlorite, Bleaching-powder,* E.; *Chlorure de chaux, Poudre de Tennant ou de Knox,* Fr.; *Chlorkalk, Bleichkalk,* G.

A compound resulting from the action of chlorine upon calcium hydroxide, and containing at least 30 per cent. U. S. (33 per cent. Br., 25 per cent. P. G.) of available chlorine. Chlorinated lime should be preserved in well-closed vessels in a cool and dry place. This preparation is often improperly called "Chloride of lime."

Preparation and Composition.—Chlorinated lime was first prepared on an extensive scale by C. Tennant and Knox, of Glasgow, in 1799, and is manufactured in essentially the same manner at the present time, the improvements introduced at various times consisting in perfecting the apparatus and the production of chlorine. Well-slaked lime, free from dampness, is rubbed through a sieve, and the powder thus obtained is spread upon shelves which are placed in several tiers in boxes or chambers, into which dry chlorine gas is conducted from the top as long as it is absorbed, care being taken to regulate the current of gas in such a manner that the temperature within the chambers does not rise higher than 25° C. (77° F.), in order to avoid the formation of calcium chlorate. According to Lunge (1881), in the presence of an excess of about 4 per cent. of moisture in the calcium hydroxide, and at a temperature of about 40° C. (104° F.), a product containing 43 per cent. of available chlorine may be obtained.

The nature of the chemical reaction taking place in the formation of bleaching-powder is as yet not perfectly clear. The main reaction is usually represented thus, $2Ca(OH)_2 + 4Cl = Ca(ClO)_2 + CaCl_2 + 2H_2O$. If it is assumed that the reaction takes place in the same way as in the action of chlorine on potassium hydroxide, the product is a mixture of calcium hypochlorite, $Ca(ClO)_2$, and calcium chloride, $CaCl_2$,

for in the case of potassium hydroxide this reaction is accepted: $2KOH + 2Cl = KClO + KCl + H_2O$. An objection to the view that calcium chloride is present as such in bleaching-powder is the fact that the latter is not deliquescent, as it should be if calcium chloride were present, and that alcohol does not dissolve one-half of the chlorine as calcium chloride, as it should if the latter were present. This has led to the suggestion that bleaching-powder in the dry form is not a mixture, but rather one compound, $Ca<^{Cl}_{OCl}$ or $CaOCl_2$. This practically is equivalent to a mixture of the two compounds above in molecular proportions, for $Ca(ClO)_2 + CaCl_2 = 2CaOCl_2$. It is difficult to decide on the nature of bleaching-powder, but at present the evidence seems to be in favor of the view that, in the dry form, it is a single compound of the composition $CaOCl_2$. When treated with water, however, it appears to be decomposed into a mixture of hypochlorite and chloride. Erdmann (*Anorg. Chemie*, 1900) states that, besides the hypochlorite, basic hypochlorite, (HO)CaOCl, and the compound $Ca<^{Cl}_{OCl}$, are assumed to be present in bleaching-powder; that $CaCl_2$ is always present, and often calcium oxychloride, Cl–Ca–O–Ca–OH. That aqueous solutions of chlorinated lime contain calcium hypochlorite was proved by Kingzett, who obtained this salt from concentrated solutions of the former placed in a freezing-mixture or evaporated in a vacuum over sulphuric acid. Schorlemmer, Lunge, and others have shown that with nitric or sulphuric acid carefully added, avoiding excess, a distillate containing hypochlorous acid is obtained; that carbon dioxide liberates in the solution hypochlorous acid; and that, after exhausting chlorinated lime with little water, the subsequent solutions contain calcium and chlorine uniformly in the proportion required by the formula $CaOCl_2$.

Nearly all the chlorine manufactured is brought into the market stored up in the form of bleaching-powder.

Properties.—Chlorinated lime is a white or whitish powder or in friable lumps, dry or but slightly damp, with a faint odor of chlorine, and a disagreeable bitter and saline taste. It is soluble in about 20 parts of water, though the commercial product always leaves a slight residue, mainly calcium hydroxide. The solution has an alkaline reaction on litmus, which is finally bleached. On exposure to the air, it absorbs and combines with carbon dioxide, liberating chlorine and becoming moist: $CaCl_2 + Ca(ClO)_2 + 2CO_2 = 2CaCO_2 + 4Cl$. It is wholly soluble in dilute acetic acid (not more than a trifling residue of insoluble matter should be left, U. S.), with the evolution of chlorine. With hydrochloric or sulphuric acid, chlorine is liberated, the action taking place presumably in two stages; thus, (1) $Ca(ClO)_2 + H_2SO_4 = CaSO_4 + 2HClO$, and $CaCl_2 + H_2SO_4 = CaSO_4 + 2HCl$; (2) $2HClO + 2HCl = 2H_2O + 4Cl$. It is evident that the amount of chlorine evolved, which is designated *available chlorine*, depends on the proportion of hypochlorite, $Ca(ClO)_2$, present. If there is a larger percentage of $CaCl_2$ than is indicated by $(Ca(ClO)_2 + CaCl_2)$, its chlorine will not be liberated, and is therefore not *available chlorine* for bleaching purposes.

A solution of bleaching-powder alone bleaches very slowly, but the action is hastened by adding such substances as will liberate chlorine; for example, carbonic, hydrochloric, or sulphuric acid. Certain salts, by producing unstable hypochlorites, also hasten the bleaching action. A concentrated solution of bleaching-powder when heated liberates oxygen; thus, $Ca(ClO)_2 = CaCl_2 + O_2$. In dilute solution, however, the hypochlorite is converted into chlorate and chloride: $3Ca(ClO)_2 = Ca(ClO_3)_2 + 2CaCl_2$. When heated in contact with certain oxides, as those of copper and iron, manganese, and mercury, and with cobalt and nickel hydroxides, the solution gives off oxygen readily. Distilled with alcohol, wood spirit, some volatile oils, etc., bleaching-powder generates chloroform, and when it is mixed with certain organic substances in the dry state, a gradual decomposition and development of heat take place, and may result at last in an explosion. The spontaneous explosions of chlorinated lime which are on record may probably be referred to such a cause.

Tests.—The only essential test to be made of bleaching-powder is for its strength in available chlorine, carried out in the U. S. as follows:

If 3.52 Gm. of chlorinated lime be thoroughly triturated with 50 Cc. of water and carefully transferred, together with the washings, into a flask, and water added to make 1000 Cc., and after thoroughly shaking, if 100 Cc. be taken, and then 1 Gm. of potassium iodide and 5 Cc. of diluted hydrochloric acid added, the reddish-brown liquid, to

which, toward the end of the titration, a few drops of starch test-solution are added, should require, for complete decoloration, not less than 30 Cc. of decinormal sodium thiosulphate solution (each Cc. corresponding to 1 per cent. of available chlorine). The Br. and P. G. methods differ from the above only in the quantities of substances employed, the required percentage being respectively 33 and 25.

In the process the liberated chlorine reacts with potassium iodide, $KI + Cl = KCl + I$, setting free an equivalent amount of iodine. This reacts with the sodium thiosulphate to form sodium iodide and tetrathionate: $I_2 + 2Na_2S_2O_3 = 2NaI + Na_2S_4O_6$. The end of the titration is reached when the blue color of the iodized starch just disappears.

Other methods of titration may be employed, and in the arts that of Penot and Mohr is generally used. In this method the hypochlorite is made to oxidize arsenous acid in a solution of potassium arsenite, the excess of arsenous acid being determined by iodine solution, and from the quantity of arsenous acid oxidized the equivalent of chlorine is calculated. The reaction is $As_2O_3 + 2Cl_2 + 2H_2O = As_2O_5 + 4HCl$.

Lunge, 1886, devised the method in which hydrogen peroxide is acted on by bleaching-powder, oxygen being liberated in equal amounts from each compound; thus, $CaOCl_2 + H_2O_2 = CaCl_2 + H_2O + O_2$ The oxygen is measured in a nitrometer, and its volume is equivalent to the volume of available chlorine.

In France, the strength of bleaching-powder is expressed in chlorometric or Gay-Lussac degrees. Each degree denotes 1 liter of chlorine gas at normal temperature and pressure obtained from 1 kilogram of bleaching-powder. The French Codex demands at least 90 degrees of chlorine, which is equal to 28.62 per cent. by weight.

Action and Uses.—When locally applied or given internally, bleaching-powder acts as a decided irritant, and if taken internally in overdose causes violent gastro-enteritis, with nausea, vomiting, and diarrhœa. Unless its effects are counteracted, it may also produce gangrene of the stomach followed by perforation. If the fumes of chlorine which it gives off are inhaled, they produce a sensation of suffocation followed by considerable bronchial irritation. Because of its property of absorbing moisture it acts as a desiccant and inhibits the growth of micro-organisms. The free chlorine contained in chlorinated lime also has the power of decomposing compounds of hydrogen sulphide, hence the preparation is largely employed as a disinfecting agent. Chlorinated lime is probably the best substance we can employ to disinfect the urine, fecal discharges, and sputa of patients suffering with infectious diseases. It is also valuable for sewers, privies, dissecting-rooms, and other places where noxious odors are present. Solutions of the drug may also be injected into the uterus containing disorganized clots and pieces of retained placenta. A 1 per cent. solution has been recommended as a mouth wash for ulcerative stomatitis, ulcerated gums, mercurial ptyalism, and as a gargle in the treatment of putrid sore throat. A 5 per cent. solution is also said to be useful in treating purulent ophthalmia, and when applied upon lint is a successful remedy for chilblains. Itch and other cutaneous eruptions are stated to be cured by the application of this lotion. An ointment made with 1 part of the drug and 3 of lard may be applied by inunction in the treatment of scrofulous enlargement of the lymphatic glands and dry sluggish ulcers. Internally the drug has been employed as a stimulant during the course of low fevers, and its administration is said to be valuable in phthisis and chronic bronchitis when the expectoration is profuse and purulent. Persons poisoned with sewer gas and hydrocyanic acid are said to be benefited by holding over the nose a cloth saturated with a solution of chlorinated lime.

The internal dose of chlorinated lime is from 1 to 5 grains (0.06–0.30 Gm.), largely diluted with water. For disinfecting purposes 1 part of the powder in 50 parts of water is usually sufficient, but because of its comparative inexpensiveness a saturated solution may be prepared, especially for use in the sick-room.

CALX SULPHURATA, *U. S.*, *Br.*—Sulphurated Lime.

Calcaria sulfurata, Hepar sulphuris calcareum, Hepar calcis.—Crude calcium sulphide, E.; *Sulfure de chaux,* Fr.; *Kalkschwefelleber,* G.

A mixture containing at least 60 per cent. of calcium monosulphide [CaS = 71.63], together with unchanged calcium sulphate [$CaSO_4 = 135.15$] and carbon, in varying proportions.—U. S.

A mixture containing not much less than 50 per cent. of calcium sulphide (CaS). — Br.

Preparation.—Dried gypsum, in fine powder, 70 Gm.; charcoal, in fine powder, 10 Gm.; starch, 2 Gm. Mix them thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small glass-stoppered vials.—U. S.

In place of metric weights, the following proportions may be used in avoirdupois weight: Dried gypsum, 3½ ounces; charcoal, ½ ounce; starch, 44 grains.

The reaction taking place when the mixture is heated consists in oxidation of the charcoal at the expense of the calcium sulphate, a part of the latter being converted into calcium sulphide: $CaSO_4 + C_2 = CaS + CO_2 + 2CO$; the resulting carbon monoxide and dioxide pass off as gases. The starch assists in the reduction.

The former Br. process is very similar: Calcium sulphate (nearly anhydrous), 7 ounces; wood-charcoal, 1 ounce; both in fine powder; mix thoroughly; heat to redness in an earthen crucible until the black color has disappeared; cool, and at once place the whitish residue in a stoppered bottle. The present Br. gives no quantities.

Properties.—Sulphurated lime is a pale-gray powder, gradually altered by exposure to the air, exhaling a faint odor of hydrogen sulphide, having an offensive alkaline taste and an alkaline reaction, very slightly soluble in water and insoluble in alcohol; boiling water partially decomposes it. On dissolving sulphurated lime with the aid of acetic acid, hydrogen sulphide is abundantly given off and a white precipitate (calcium sulphate) is thrown down. The filtrate yields, with ammonium oxalate test-solution, a white precipitate soluble in hydrochloric, but insoluble in acetic acid.—U. S.

Tests.—If 1 Gm. of sulphurated lime be gradually added to a cold solution of 2.08 Gm. of cupric sulphate in 50 Cc. of water, followed by 10 Cc. of diluted hydrochloric acid in small portions with constant stirring, and the mixture be digested on a boiling water-bath for 15 minutes and filtered, the addition of an excess of ammonia water should impart no color to the filtrate (presence of at least 60 per cent. of pure calcium sulphide).—U. S. The equation, $CuSO_4.5H_2O + CaS = CuS + CaSO_4 + 5H_2O$, shows that 247.85 parts of cupric sulphate require 71.63 parts of calcium sulphide for complete decomposition, and 1.73 Gm. will therefore require 0.493 + Gm., which is practically 50 per cent. of 1 Gm. The Br. process is similar.

Action and Uses.—Sulphurated lime is recommended as a useful remedy in the treatment of acne and furunculosis. It allays inflammation and hastens suppuration, so that patients taking it may be made temporarily worse. A solution of the drug has been locally applied in the treatment of itch and ringworm, and it is said that the former disease is rapidly and effectually cured by it. Baths containing this remedy are stated to be efficacious in the treatment of chronic rheumatism, chronic bronchitis, and pulmonary tuberculosis. A strong solution of the drug has also been applied locally for the purpose of removing superfluous hair. It is allowed to remain 15 or 20 minutes, after which it is removed with a wet cloth or sponge, the detached hair being removed at the same time.

The internal dose is from $\frac{1}{10}$ to ½ grain (0.005–0.03 Gm.), 3 times daily. If this remedy is not obtainable for the treatment of furunculosis, powdered baked egg-shells may be given in 1-drachm (4 Gm.) doses 3 times daily.

Allied Compounds.—Calcii Sulphidum *s.* Sulphuretum *s.* Sulfuratum. *Calcium sulphide*, E.; *Sulfure de calcium*, Fr.; *Schwefelcalcium*, G. Formula, CaS. Molecular weight, 71.63.—The pure sulphide can be prepared by heating calcium sulphate in hydrogen or by heating calcium oxide in hydrogen sulphide gas, or the carbonate in a mixture of carbon disulphide vapor and carbon dioxide. It is a white substance, smelling of hydrogen sulphide in moist air, and almost insoluble in water. It is phosphorescent in the dark after exposure to light. It is not used in pharmacy or the arts.

Calcii Oxysulphuretum, known in France as *sulfure de calcium* or *foie de soufre calcaire*. This misnomer is applied to a mixture of calcium pentasulphide and calcium thiosulphate, obtained by boiling 1 part of quicklime and 2 parts of sulphur with water: $3CaO + 12S = 2CaS_5 + CaS_2O_3$. The same reaction takes place in the preparation of

Liquor Calcii Sulphurati.—*Vleminckx's solution, Golden lotion.*—This is prepared by slaking 1 part of lime and boiling with 2 parts of sulphur and 20 parts of water until the filtrate yields 12 parts of a yellowish-red liquid which, with acids, gives hydrogen sulphide and sulphur. It should be kept in small well-filled bottles, and is useful in treating acne.

Martin's Depilatory.—A soft mass, containing calcium hydrosulphide, Ca2HS, is prepared from 2 parts of slaked lime and 3 of water, by passing into the mixture hydrogen sulphide as long as it is absorbed. The mass has a strong sulphurous odor, and on standing separates into two portions, which are to be mixed when used; if properly prepared, an application for 8 or 10 minutes is sufficient for removing the hair.

Phosphorescent Powder or Paint.—Calcined oyster-shells or cuttlefish-bone, 100 parts; caustic lime, 100 parts; calcined sodium chloride, 25 parts; mix and thoroughly incorporate from 20 to 25 per cent. (about 55 parts) of sulphur and from 3 to 7 per cent. (about 8 to 18 parts) of calcium, barium, strontium, or magnesium sulphide. The luminosity may be increased by adding incinerated marine algæ. The powder is rendered adhesive by means of varnish, collodion, etc. After exposure to sunlight it becomes luminous in the dark. A similar compound is *Canton's phosphorus* (1768), prepared from burnt oyster-shells, 2 parts, and sulphur, 1 part.

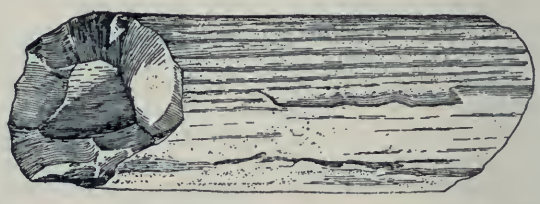
CAMBOGIA, *U. S., Br.*—Gamboge; Pipe Gamboge.

Gambogia, U. S. 1870; *Gutti*, P. G.; *Gummi-resina guttæ* (*s. gutti*), *Gutta gamba*, *Cambodia*; *Gummigutt*, *Gutti*, G.; *Gutte*, *Gomme-gutte*, Fr.; *Gomma gotta*, F. It.; *Goma guta*, *Guta Gamba*, Sp.; *Tamala*, Sansk.

A gum-resin obtained from *Garcinii Hanburii* Hook. f. (Fam. *Guttiferæ*).

Origin.—The specific distinctions in this group of plants being very difficult of diagnosis, and the genus none too well known, the specific identity of the gamboge plant is by no means certain, and a variety of names for it are found in various works. It is a rather small tree which abounds in the forests of farther India, especially the province of Cambodia, in Siam, one of the names applied to the product. Latex-tubes exist both in the bark and in the deeper tissues, and the yellowish milk-juice is obtained by making a single deep incision running spirally about the trunk, from a height of about 3 meters

Fig. 74.



Pipe gamboge (⅔ Nat.).

to the ground. The juice runs into a receptacle placed at the lower end of this incision, and is thence transferred usually to hollow bamboo-joints. Here it dries in about a month, at the same time contracting toward the sides, so as to leave a cylindrical cavity at the center, forming the official *pipe* gamboge, so highly esteemed. Upon tearing off the bamboo covering, the latter leaves impressions of its fibers upon the pipe. *Saigon* or *Cochin* gamboge is moulded into little cakes while semisolid, and wrapped in leaves, paper, or cloths until hard. It is regarded as more liable to adulteration than the pipe, but may be of perfect quality. Occasionally, the article is pressed or run into large masses, in boxes or tubs, and is then frequently of poor quality or highly adulterated, sometimes with large stones or pieces of iron, in one lot in our possession, with a large number of railroad spikes, the quality of the drug being thus greatly injured, aside from the fraud in weight. Broken gamboge frequently contains considerable fragments of rice-paper, and is then characterized as "ricey."

Description.—In cylindrical pieces, usually hollow at the center, 2 to 5 Cm. (1 to 2 In.) thick, longitudinally striate on the surface; fracture flattish-conchoidal, smooth, of a waxy luster, orange-red; inodorous; taste very acrid. The powder is bright-yellow, sternutatory, practically free from starch. Gamboge should yield not less than 75 per cent. of alcohol-soluble matter and not more than 3 per cent. of ash.

It yields with water a uniform bright-yellow emulsion, which forms with ammonia water a clear deep-red, afterward brown solution, and with potassium or sodium hydroxide an orange-red solution, the liquid decolorized by acids, and the yellow resin being precipitated.

The Russian Pharmacopœia prints a special caution against gamboge of a brownish-red color, dull fracture, and with small holes. The Italian specifies 60 to 80 per cent. of resin and 15 to 25 per cent. of gum. Pipe gamboge is almost always pure, but the powdered article very commonly contains small quantities of starch, apparently not added with intent to adulterate.

Constituents.—Gamboge contains 15 to 20 per cent. of gum analogous to arabin,

60 to 80 per cent. of resin (*cambogic acid*), a volatile oil, a phenol ester, methyl alcohol and other alcohols, isovitinic and acetic acids, and a liquid with a fruity odor having the nature of an aldehyde or a ketone. Phloroglucin is probably a decomposition-product. The resin has a deep-orange color, and turns red with alkalies, with which it forms soluble salts. It is soluble in alcohol, ether, and chloroform, and with salts of the heavy metals forms precipitates called *cambogiates*.

Action and Uses.—Gamboge is rarely prescribed in medicine except in combination with other cathartics. If employed alone in full dose, it acts as a powerful hydragogue cathartic, causing severe intestinal irritation, considerable griping, and at times nausea and vomiting. Poisonous doses cause a severe gastro-enteritis, which may be followed by death. Gamboge may be employed in the various conditions in which hydragogue catharsis is indicated; for example, in hepatic congestion, renal dropsy, uræmic conditions, and congestion of the brain. It has also been employed for the removal of tænia, but when given for this purpose is usually combined with tænicides.

The ordinary dose of gamboge is from 2 to 5 grains (0.12–0.30 Gm.), but for the removal of tænia this amount may be doubled. It may be prescribed either in pill, emulsion, or solution, made by the addition of potassium carbonate.

Related Products.—*G. collina* Vieill, of New Caledonia, yields a product very similar to gamboge, described by Heckel and Schlagdenhauffen (*Rep. de Pharm.*, [3] 5, 193). It differs in its color, which is more nearly an orange, in yielding pyrocatechin as a decomposition-product, and in yielding a white crystalline body behaving like tannin in colored solution when dissolved in alcohol. The product yields about 75 per cent. of resin and 15 per cent. of gum soluble in water. Its physiological properties do not appear to have been tested.

Inferior kinds of gamboge are also yielded by *G. venulosa* Chois. and *G. Cambogia* Desr.

CAMPHORA, *U. S., Br., P. G.*—Camphor.

Kampher, Campher, G.; *Camphre, Camphre du Japon*, Fr.; *Canfora (del Giappone, delle Laurinee)*, It.; *Alcanfor*, Sp., Port.

The dextrogyrate modification of the saturated ketone, $C_9H_{16}CO$, obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier (Fam. *Lauraceæ*), and purified by sublimation. Camphor should be kept in well-closed vessels in a cool place.—U. S.

Origin.—A handsome evergreen tree somewhat resembling the sassafras, all parts having a strong odor of camphor, native of eastern Asia and the adjacent islands, and widely introduced into warm countries as a shade and ornamental tree. It does very well in Southern California, where trees presumably 40 years of age are 60 feet in height and 3 feet in diameter at the base, as well as in the southeastern United States. The wood is white, fragrant, and repels insects, and is highly prized. The production of camphor is carried on in China, Japan, and Formosa. An estimate in 1895 placed the Japanese product at about 300,000 pounds; the Chinese, 200,000 pounds; the Formosa, 6,000,000 to 7,000,000 pounds. The annual consumption in the United States is estimated at 2,000,000 pounds. The methods of obtaining differ slightly in different localities, but agree in their main features, as follows: The trees are not considered worth working until they have reached an age of 50 years. They are selected by a camphor-expert, who scratches into the wood and examines it for the relative amount of camphor contained. If satisfactory, the wood of the root, and about 8 feet of the trunk-base, is distilled. The wood is cut obliquely into chips about $\frac{1}{8}$ inch thick and 2 inches long and broad. These are closely packed into some sort of a steam chamber, often only inverted rude earthen pots, the steam driving off the vapor of the camphor, which is condensed, collected, and drained of its oil, then pounded or pressed into barrels as crude camphor. A Japanese laborer will collect about 230 pounds of chips daily. In Formosa, 4 laborers are said to make from 125 to 175 pounds of crude camphor in a month. The yield from the wood varies most widely. Both in China and Formosa the production is carried on in a country of savages, so that government protection is required. To provide funds for this purpose, the Chinese Government has charged a camphor tax. The oil is highly esteemed in China for external application, and is also used as a lighting and burning fluid. The crude camphor of the different producing regions presents differences, that of Japan being lighter-colored, more pinkish and coarser-grained, dry to the touch, and much more valuable than that of Formosa, although new conditions are now leading to great improvement in the quality of the

latter. The distillation of the branches, formerly reported, is not now practised. Hooper has distilled the leaves, obtaining about 0.5 per cent. of an oil, three-fourths of which was camphor.

As a result of the Japanese-Chinese War, Japan has seized the opportunity to monopolize the Formosa industry, with revolutionary results to the trade. She has established a frontier protection-force of nearly 2000 police, has undertaken to stop the destructive methods so long in vogue, and has established a system of replanting, notwithstanding that the Formosa camphor forests are practically inexhaustible, and has undertaken to raise the standard of quality. At the same time, she has arranged to steady the market as to both supply and price. All collectors are required to sell their produce to her at a fixed price, about 15 dollars a *picul* (about 133 pounds), if the article attains to her standard for crude camphor. This product is refined at the government works at Taikohu, Formosa, several thousand pounds at one charge. In refining, the water and oil are first driven off by a low heat; the aperture is then closed and another established, through which the camphor is sublimed. The product is then pressed into blocks, for export, in hydraulic presses. Sales and the selling price are equally controlled by Japan. The monopoly dates from August 5, 1899, but did not become effective until March 24, 1900, when bids were invited for taking the selling agency for the entire product, on the following terms:

The holder of the agency was to conduct the sale of the camphor at London, Hamburg, New York, and Hongkong, and be prepared to accept from the government from 30,000 to 50,000 piculs of camphor a year. The camphor was to be of two classes: "A," to be known as "cleaned and pressed," and "B," which is camphor in its ordinary crude form. When the amount of camphor to be turned over to the selling agents exceeded 50,000 piculs a year, the selling price for the excess would be determined by the Formosa government in concert with the selling agents. The government would prepare and pack the camphor for shipment, and the agents should not change the wrapping or package, nor place other materials among the contents. So far as in their power, the selling agents should send such quantities of camphor to various leading markets (London, Hamburg, New York, Hongkong, etc.) as were necessary to supply the demand. The term of the contract between the government and the selling agents was to be for 3 years. For the use of the government, and also as raw material for the purpose of manufacture in the Japanese Empire, the Formosa government might sell camphor at the same price to persons other than the selling agents. However, this extra-official sale would not affect the minimum limit of the quantity to be sold by the agents. The government required of the selling agents a substantial guaranty, this being permitted to take the form of a deposit with the local government of Formosa State bonds. Furthermore, the government reserved the right to interfere should the selling agents impair the government's camphor monopoly interests by acts of "inordinate selfishness or of an illegitimate nature."

Although the government has generally recommended the sale of the semirefined ("cleaned and pressed") grade, owing to the saving of loss in weight, etc., it has been announced that the crude form of the drug will be furnished to consumers specially applying for it through the regular channels.

An English firm was the fortunate recipient of the agency, its tender being the most favorable—that is, it was prepared to conduct the business on the cheapest basis. The prices which will be asked for the drug abroad have been announced as follows: For "A" grade camphor blocks in London, Hamburg, and New York, 107.843 yen per picul ($53.92 per 133 pounds), exclusive of import duties if any, and Hongkong 102.378 yen. For crude camphor, 99.702 yen ($49.85) will be the price abroad. The government will receive from the selling agents 85 yen ($42.50) a picul for the crude, and 95 yen ($47.50) for the "A" grade. (*U. S. Consular Report.*)

As a result of this arrangement, purchasers are now able to demand camphor at the above-named prices from the selling agents. The profits to the Japanese Government are estimated at about seventeen dollars per picul.

Much time and money have been expended in efforts to produce camphor artificially; but, although similar substances have been produced, it has been found impossible, so far as this one is concerned, to produce it upon an important commercial scale. A patent was granted April 29, 1902, to Nathaniel Thurlow, for making artificial camphor, the process being based on the interaction of anhydrous turpentine and anhydrous oxalic acid at a temperature of 120°–130° C. (248°–266° F.), the products resulting being borneol, borneol oxalate, borneol formate, camphor, and polymerization-products. The principal method heretofore has been by oxidizing oil of turpentine by means of ozone conducting chlorine gas through terebentene distilled from crude turpentine, purifying

depositing by an alkaline carbonate, heating to 120° C. (248° F.), and exposing the vapor to the action of ozone.

Properties.—Refined camphor is white, translucent, crystalline in texture, fissured in the interior, tough, and not pulverizable, except after moistening it with alcohol, ether, chloroform, or a volatile oil. It evaporates slowly at the ordinary temperature, and condenses in partly filled bottles in the form of glossy hexagonal plates or prisms. Various contrivances have been suggested to keep camphor in the powdered condition, such as precipitation by water in the presence of magnesia, trituration with a fixed oil, glycerin, or sugar; but the most satisfactory method appears to be that proposed by J. C. Lowd (1871), of condensing the hot camphor vapors in a large chamber. The powder thus obtained, which has been called *flowers of camphor*, may be preserved for some years if kept in a cool place, and even if it should cake together may readily be reduced to the pulverulent condition. Another method is that proposed by Dr. Bruno Hirsch, pouring a hot concentrated alcoholic solution of camphor into 10 times its volume of distilled water, stirring constantly, collecting the precipitate on a strainer, and after it has drained drying it over lime, calcium chloride, or sulphuric acid, without subjecting the powder to pressure.

Camphor fuses at 175° C. (347° F.), boils at 204° C. (399° F.), sublimes without residue, and when ignited burns with a luminous sooty flame; its specific gravity at 25° C. (77° F.) is 0.990; its solutions are dextrorotatory. It is sparingly soluble in water (see Aqua Camphoræ), dissolves at 15° C. (59° F.) in 0.7 part of alcohol, and is freely soluble in ethers, chloroform, glacial acetic acid, wood spirit, acetone, carbon disulphide, benzene, benzin, and volatile and fixed oils; its solutions in alcohol and ether increase the solubility of corrosive sublimate, and the presence of this salt renders camphor more soluble in these liquids (see Hydrarg. Chlor. Corros.). Camphor dissolves by trituration in 10 parts of milk, and the solution may be diluted with water without causing precipitation. When triturated with hydrated chloral, menthol, thymol, phenol or resins, the mixtures gradually become soft or liquid, and in the fused state resins dissolve a considerable proportion of camphor. It has a peculiar penetrating odor and an aromatic, somewhat cooling taste. The odor of camphor is destroyed by Tolu balsam, asafetida, and similar umbelliferous resins. Thrown upon water, camphor shows a peculiar rotatory motion, which is probably caused by its rather rapid evaporation and slow solubility. On exposure to the air, it evaporates more or less rapidly at ordinary temperatures, and, when moderately heated, it sublimes without leaving a residue. If a small piece of camphor be dropped into a small porcelain dish, the latter placed in a larger dish, and a clean beaker moistened on the inner surface with distilled water be inverted over the smaller dish, after igniting the camphor, a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water, and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate test-solution (absence of chlorinated products).—U. S.

Its composition is represented by the formula $C_{10}H_{16}O$. When distilled with zinc chloride or phosphoric anhydride, it is gradually converted into cymene, $C_{10}H_{14}$, and by oxidation with nitric acid into *camphoric acid*, $C_{10}H_{16}O_4$, and finally into *camphoronic acid*, $C_9H_{12}O_5$. Schwanert's *camphresinic acid* (1863) is a mixture of these two. *Nitrosocamphor*, $C_{10}H_{15}O.NO$, was prepared by Claisen and Manasse (1889) by treating camphor and amyl nitrite, dissolved in ether, with sodium ethylate; it melts at 153° C., and is readily soluble in water, alcohol, ether, and chloroform. By the action of hypochlorous acid on camphor, Wheeler (1868) obtained several chlorine substitution-products, and by acting upon these with alcoholic solution of potassium hydroxide, *oxycamphor*, $C_{10}H_{16}O_2$, is formed, which crystallizes in needles, has the odor and taste of camphor, and sublimes without change, but melts at 137° C. (278.6° F.). Camphor combines and forms also substitution-compounds with iodine and bromine.

Camphoric acid has been synthetically prepared, beginning by chlorinizing a mixture of ethyliso-butyrate and ethyl aceto-acetate.

Pharmaceutical Preparations.—Acid Camphor Mixture, N. F.; Aromatic Camphor Mixture, N. F.; Camphor Cerate, U. S. P.; Camphor Liniment, U. S. P.; Camphor Ointment, N. F.; Camphor Water, U. S. P.; Camphorated Tincture of Opium, U. S. P.; Compound Camphor Cerate, N. F.; Parrish's Camphor Mixture, N. F.; Soap Liniment, U. S. P.; Spirit of Camphor, U. S. P.

Action and Uses.—Applied to mucous membranes in concentrated form, camphor

acts as a stimulant and irritant. If placed in the mouth, it produces a sensation of burning. Internally, its effect depends chiefly upon its dose. Large amounts cause a burning pain in the œsophagus, stomach, and abdomen, followed by vomiting, feebleness of the pulse, disturbances of vision, muscular feebleness, and pallor of the skin. If the quantities have been very large, epileptiform convulsions may develop. Death produced by camphor in a healthy person is, however, almost unknown. When taken in large dose the drug has been said to act as a sexual stimulant; but this is probably incorrect.

Camphor has been employed in medicine very largely in a number of widely different conditions. Probably its most valuable use is as a diffusible stimulant for the purpose of supporting the system during a crisis in a severe illness, or when collapse is threatened. Under these circumstances, it is best administered in sterilized oil by the hypodermic needle. It is also an efficient remedy in the treatment of serous diarrhœa accompanied by abdominal pain, and in the treatment of cholera morbus and true Asiatic cholera it is exceedingly valuable. It is also used with success in the treatment of hiccough and cardiac palpitation. Dissolved in alcohol, camphor affords a good lotion in muscular sprains and bruises, and is often sopped upon the scalp for the relief of nervous headache. Taken internally in small, frequently repeated doses, camphor is a useful remedy in the earliest stages of acute coryza.

The dose of camphor is from $\frac{1}{2}$ to 2 grains (0.03–0.12 Gm.), given in pill; of the spirit of camphor, $\frac{1}{2}$ to 2 fluidrachms (2–8 Cc.); and of camphor-water, 1 fluidrachm to $\frac{1}{2}$ fluidounce (4–16 Cc.).

Other Camphors.—The crystallizing stearoptens of volatile oils are sometimes designated as camphors.

Borneo Camphor or Borneol (*Sumatra*, *Bhimsaim*, or *Barus camphor*) is camphyl alcohol ($C_{10}H_{18}O$). It occurs in many plants of widely separated families, but has been obtained for commercial purposes from cavities in the wood of *Dryobalanops aromatica* Gaertn. (*D. Camphora* Colebrooke.—Fam. *Dipterocarpaceæ*), a large tree of Borneo and Sumatra. In young trees it exists as a liquid, in old ones as a solid. The deposits are mostly near the branch-swellings. About 11 pounds is a good yield for a tree. The natives test the trees by piercing them. To obtain the product, the wood has to be broken into small splinters. Trees which do not contain it, will usually produce it in 7 or 8 years after this piercing, which suggests that the substance is deposited as an antiseptic measure. Borneol is dextrogyre, heavier than water, and not volatilized at ordinary temperatures, so does not collect in crystals on the sides of its glass container. Nitric acid converts it into ordinary camphor. Under the name of *Ngai camphor*, it is distilled in the Himalayas from the weed *Blumea Balsamifera* DC. (Fam. *Compositæ*).

CAMPHORA MONOBROMATA, *U. S.*—Monobromated Camphor.

Bromo-camphor, *Bromated camphor*, E.; *Camphre monobromé*, Fr.; *Monobromkampher*, *Bromkampher*, *Kamphermonobromid*, G.; *Canfora monobromata*, F. It.; *Bromuro de alcanfor*, Sp.

Formula, $C_{10}H_{15}BrO$. Molecular weight, 229.34.

Monobromated camphor was obtained by Swarts (1861) by heating camphor dibromide, $C_{10}H_{16}O.Br_2$, in sealed tubes, and by W. H. Perkins (1865) by distilling "bromated oil" (Laurent, 1840) and collecting the distillate above 265° C. (509° F.).

Preparation.—Monobromated camphor may be prepared by the process of Maisch. Break 13 ounces of camphor into small pieces; put these into a quart retort, first filling the neck; raise the latter somewhat, and then introduce through the tubulure, by means of a funnel-tube, 4 ounces of bromine, washing the last down with 20 or 30 minims of alcohol. A brisk reaction will commence in about 15 or 20 minutes; after it has subsided and the retort has become cool introduce 8 to 9 ounces of bromine in 4 portions, waiting after each addition until the reaction has ceased. The addition of alcohol is not requisite, but facilitates the reaction, and the bromine may be added in larger quantities if provision be made for condensing the vaporized bromine and returning it to the retort. This is now slowly heated to about 132° C. (270° F.), allowed to cool, the contents dissolved in warm petroleum benzin, the solution allowed to crystallize, and the crystals purified by recrystallization from hot alcohol or petroleum benzin. On evaporating the mixed mother-liquors an oily mass is obtained, which, heated to 260° C. (500° F.), becomes black, and contains monobromated camphor, to be obtained by recrystallization as before. In this process, as well as the various modifications of the same, camphor dibromide, $C_{10}H_{16}OBr_2$, is first formed, and this, on being heated, is decomposed into

hydrobromic acid, HBr, and monobromated camphor, $C_{10}H_{15}BrO$, the latter representing a molecule of camphor in which 1 atom of hydrogen is replaced by 1 of bromine. During the operation one-half of the bromine used is given off as hydrobromic acid, and may be collected in water or combined with a base.

Properties.—Monobromated camphor crystallizes from alcohol in thin white or colorless prisms and needles, and from petroleum benzin in long, flat prisms or glossy scales. It has a weak but persistent camphoraceous odor and taste, and a neutral reaction. It is permanent in the air and not affected by direct sunlight. It is almost insoluble in water, slightly soluble in glycerin, freely soluble in alcohol, ether, chloroform, fixed oils, and in less than its weight of hot petroleum benzin, from which solution the greater part crystallizes on cooling. It melts at 76° C. (168.8° F.), and evaporates slowly with the vapors of boiling water, condensing in fine white interlaced needles; at 274° C. (525° F.) it boils and volatilizes completely, with partial decomposition. It dissolves without decomposition in cold sulphuric acid, and is again precipitated by water. When boiled with silver nitrate and nitric acid it is decomposed, and yields 81.2 per cent. of silver bromide. Heated with zinc chloride to near 160° C. (320° F.), it yields a hydrocarbon, C_8H_{16}, and liquid thymol, $C_6H_3.CH_3.C_3H_7.OH$ (Schiff, 1880). Sodium amalgam reduces it to camphor; heated with nitric acid bromo-nitro-camphor and camphoric acid are formed.

Tests.—Monobromated camphor should consist of colorless crystals, neutral in reaction, melt at 76° C. (168.8° F.) (U. S.), volatilize completely on heating, boil at 274° C. (525° F.) (U. S.), and when 0.5 Gm. is boiled with 1 Gm. of silver nitrate in 25 Cc. of water for 2 hours it should yield 0.406 Gm. of silver bromide. The solution from 0.5 Gm. of monobromated camphor shaken with 10 Cc. of water and filtered, should not give a turbidity on the addition of test-solution of silver nitrate.

A β-monobromcamphor is prepared by the action of bromine upon camphor in presence of alcohol, and is separated from the α-monobromcamphor by crystallization from alcohol, in which the former is the more soluble. It may be distilled in vacuo without modification, but when distilled under ordinary pressures it begins to boil at 250° C. (482° F.), and gradually changes to the α variety, its boiling-point rising to 265° C. (509° F.). The rotatory power of β-monobromcamphor is $[\alpha]_d = +34.9°$, and for α-monobromcamphor $[\alpha]_d = +139°$.

Action and Uses.—Monobromated camphor was introduced into medicine as a substitute for camphor with the idea that it would act more powerfully as a sedative upon the nervous system. As a matter of fact, it has little advantage over and above camphor itself. It is chiefly employed to allay nervous irritation and for insomnia in neurotic persons. It is also largely used in headache powders and headache tablets combined with one of the coal-tar products and caffeine.

The dose of monobromated camphor, which is best given in capsules or tablets, is 2 to 5 grains (0.12–0.30 Gm.) once, twice, or thrice daily. Sometimes it is administered in the form of a mixture. Its physiological effect is closely related to that of camphor itself.

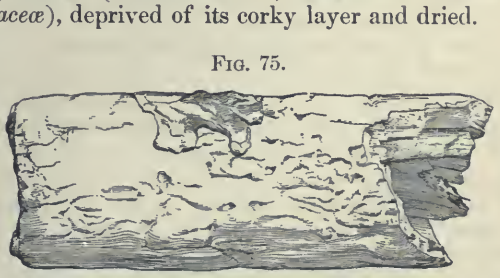
CANELLÆ CORTEX.—Canella Bark.

Canella, Costus Dulcis, False winter's bark, White cinnamon; Weisser Zimmt, Weisser Canel, G.; *Canella blanche*, Fr.; *Canela blanca*, Sp.

The bark of *Canella Winterana* (L.) Gærtn. (*Laurus W.* L.; *Winterana Canella* L.; *Canella alba* Murray.—Fam. *Canellaceæ*), deprived of its corky layer and dried.

Origin.—A small, handsome, evergreen, highly aromatic tree of the West Indies, growing also in southern Florida. The bark is originally of a silver-gray, but the corky layer is removed from the stem before collection, being loosened by beating with rude mallets. The remaining bark is then removed in quills or half-quills.

FIG. 75.



Canella alba (Nat.).

Description.—In quills or quilled strips of very variable length and breadth, sometimes nearly a yard long and 4 Cm. (1½ In.) in diameter, the bark reaching a thickness of 1 Cm. (⅔ In.) or even more; externally very hard (from a layer of stone-cells), pale-orange or

ochre-yellow, bearing transversely elongated scars, and occasionally patches of gray cork or denuded whitish spots; inner surface white, finely striate; fracture short, granular, the white middle layer dotted with numerous bright orange-yellow resin-cells, the inner layer showing wavy medullary rays; odor aromatic, somewhat cinnamon-like; taste bitterish, aromatic, and biting.

It has been used to substitute winter's bark, to which it bears little resemblance.

Constituents.—The constituents are 8 per cent. of mannit, formerly called *canellin*, mucilage, resin, a very bitter extractive, starch, and 0.5 to 1.28 per cent. of volatile oil, made up of eugenol, an oil with the odor of cajuput, and two other fractions. The ash, about 6 per cent., consists mainly of calcium carbonate. There is no tannin.

Action and Uses.—Canella is a mild aromatic stimulant and tonic. It is rarely prescribed alone, but is occasionally employed as an adjuvant to tonic and purgative remedies. It may be given in atonic dyspepsia, but is most commonly given in conjunction with aloes in the treatment of functional uterine disorders depending upon anæmia. The powdered root is given in the dose of from 10 to 40 grains (0.60–2.6 Gm.).

Very similar to canella is the nearly related bark of *Cinnamodendron corticosum* Miers, of Jamaica, there used like, and occasionally sold for it. It agrees closely in odor, taste, and constituents, but contains tannin. It is of a dark rusty brown-gray, and spotted by the scars of nearly circular warts. *C. macranthum* Baill., of Porto Rico, is also similar.

CANNABIS INDICA, *U. S., Br.*—Indian Cannabis.

Indian hemp, E.; *Indischer Hanf*, G.; *Chanvre Indien*, Fr.; *Canyama*, Sp.; *Ganja*, Ind.

The dried prepared tops of the pistillate plants of *Cannabis sativa* L. (Fam. *Moraceæ*), grown in the East Indies and gathered while the fruits are yet undeveloped, and carrying the whole of their natural resin.—U. S.

Indian hemp is official in nearly all pharmacopœias, some of which caution against the presence of fruits and brown flowers.

Origin.—From specially cultivated individuals of the ordinary hemp plant, a very tall annual which is indigenous in Asia, and is abundantly cultivated and naturalized in many countries, tropical and temperate. The rich soil and cool climate suitable for the production of hemp fiber will not develop the medicinal properties, which, moreover, are largely sacrificed by allowing the male plant to grow near, as is requisite for the production of hemp-seed. Notwithstanding these facts, large quantities of the tops of such

FIG. 76.

Cannabis Indica (¾ Nat.).

plants are marketed for medicinal use, this to a great extent explaining the weak action of much of the medicine. The following conditions, sought in the production of the Indian narcotic *ganja*, are those most favorable for the production of our drug, ganja being defined as the prepared unfertilized blossoming tops of the cultivated female plant. A hot climate, as that of Bengal, is selected, and the plants are cultivated in rows. Experts, known as "ganja doctors," examine the plants continually, marking for extraction those regarded as males, not one of which is allowed to grow in the vicinity. As maturity approaches, search is also made for male flowers growing abnormally on the female plants, and, if found, these also are removed. This exclusion of the fruiting process results in a correspondingly greater development of the active resinous exudation. The period of maturity is indicated by a brown color and the falling of the larger leaves. Harvesting must be performed within 4 days of such maturity, and the

mature plants are selected as fast as they develop. Curing consists in a series of processes for wilting, pressing, and rolling, and the shaking out of leaves and fruits, if any of the latter have formed. The rolling and treading are performed by human feet, and it is an art requiring training. Probably one object is to work the resinous matter from the stems up into the inflorescence tips. What other possible effects it may have is not known, though such have been suggested. The production of "round ganja" (*Goli*) consists in thus working each branch into a cylindrical or terete mass, and requires 4 days. That of "flat ganja" (*Chapta*) works them into a flat form, and takes but 3 days. The first-mentioned product is preferred, but our official description should include both, as it does. In both forms, the twigs are agglutinated. The Bengal or Calcutta ganja, which is the very choicest, is distinguished by its brownish or dusty, rather than the bright-green color of the Bombay. After production, Indian hemp commences at once to deteriorate. The natives say that after a year it has lost its power, and that after 2 years it is worthless. Prain reported that by the most careful possible method of preservation (close packing in boxes with perforated sides) it retained one-fourth of its power after 3½ years. Supplies of the new crop should be obtained in May or June.

Description.—Very dark-green or, preferably, slightly brownish; length 5 Cm. (2 In.) or more; densely paniculately branched, the branches compressed together and resinous-agglutinated into a terete or flattish form; bearing occasional very small, undeveloped digitate leaves of from one to several lance-linear leaflets, and numerous sheathing pointed bracts, in the axil of each of which are 2 small pistillate flowers; odor peculiar, narcotic; taste resinous and somewhat acrid; few if any small, globoidally ovoid akenes should be present, and a lens should disclose numerous resinous particles upon the surface.

The powder exhibits numerous secretion glands, on short, thick, many-celled hairs or bases, curved unicellular hairs, which frequently bear crystal masses in their bases, and rosette crystals in many of the parenchyma-cells. There should be few or no pollen-grains or stone-cells.

Quality.—The account given above of the origin of *Cannabis Indica* suffices to prove the unreliable character of much of the drug on the market. It should be added that much of this is also the product of plants which have been deprived of a great portion of their resin, before harvesting, by brushing them for the production of *churras*, as explained below. Good cannabis bears very few, if any, leaves. It is most unfortunate that in the case of such a drug we have no means of establishing a chemical standard, since the active constituent is not known. Large manufacturing houses are able to improve the standard very greatly by employing physiological tests, but the ordinary pharmacist must depend wholly upon physical examination. This requires much experience and close attention to the above description.

Constituents.—The many investigations have not yet cleared up the chemistry of cannabis. The herb contains 0.3 per cent. of a yellow aromatic volatile oil, a green resin, a bitter principle, gum, sugar, malates, potassium nitrate, etc. 10 pounds of ganja yielded 2 grains of the volatile alkaloid *cannabinine*. Hay's tetano-cannabine proved to be *choline*. Smith (1891) found a varnish-like alkaloid with the odor of coniine, and forming a sulphate which can be crystallized from alcohol. Zuco and Vignolo (1895) isolated an alkaloid, a powerful cardiac depressant, of which the hydrochloride is a colorless, deliquescent, crystalline mass. *Charras* or *Churras*, the exuded resin of cannabis, yields 33 per cent. of cannabinol, a toxic red oil claimed to be the active principle. It is, however, not a definite chemical substance, and different lots vary. Its red resin appears to be more active than cannabinol itself. By the oxidation of its cannabinol the activity of cannabis is lessened. Personne's *cannabene*, Merck's *cannabin tannate*, Bombelan's pure *cannabin*, and the *cannabindon* of Kobert (1894), are not pure active principles. The finding of nicotine by Preobroschentsky is believed to have been due to an admixture of tobacco; Dohme (1896) found that the average unselected cannabis yields 10 per cent. of resin, while the selected unfertilized tops yield 15 to 20 per cent.

Pharmaceutical Preparations.—Extract of Indian Hemp, U. S. P.; Fluidextract of Indian Hemp, U. S. P.; Tincture of Indian Hemp, U. S. P.

Action and Uses.—Cannabis indica is one of the most extraordinary drugs in the Pharmacopœia. Small doses of it are capable of producing severe and even alarming symptoms; yet, so far as we know, no case of death from an overdose of it has been reported. The drug is also extraordinary by reason of the great susceptibility of some persons to its influence, and the great insusceptibility of other persons to its effects.

These effects also vary largely with the individual, and in this respect it somewhat resembles alcohol, since its intoxication may be accompanied by hallucinations, by dreams, by pugnacity, by motiveless merriment or maudlin emotion. Perhaps its most extraordinary effect is the sensation of prolongation of time which it produces. Under its full influence, the pupils are dilated and the patient is usually in a deep sleep. Upon the general nervous system it acts as a distinct sedative.

Under the name of *haschisch*, it was taken by members of a Persian sect, the individuals of which under its influence ran amuck, killing or wounding every one in their path. In the Anglo-Saxon this homicidal mania is not developed by the drug. The habitual use of cannabis indica in excessive doses causes mental and nervous deterioration, with weak and tremulous limbs. Sometimes the cannabis indica leaves are smoked.

Cannabis indica finds its chief use in medicine as a sedative for distressing cough, the drawback being that many cases of phthisis are unduly susceptible to its cerebral effects. Combined with full doses of gelsemium, it is also largely employed for the relief of migraine and neuralgic headache. Many gynecologists also use it for its sedative influence in pelvic neuralgia, and some even assert that it has an effect upon uterine subinvolution.

Within recent years a tannate of cannabin has been introduced, and given in the dose of from 2 to 10 grains (0.12–0.60 Gm.). When it is desired to produce the therapeutic effect of the drug, it is much better to rely upon the solid or fluid extract. Much of the cannabis indica in the market has lost a large amount of its medicinal virtue, and cannot be relied upon. The physician should always employ a preparation which has been physiologically tested.

The dose of the solid extract of cannabis indica varies from $\frac{1}{4}$ to 1 grain (0.015–0.06 Gm.), according to the susceptibility of the patient; of the fluidextract, 1 to 10 minims (0.05–0.60 Cc.); and of the tincture, from 20 to 60 minims (1.3–4 Cc.).

Under the name of *cannabinon*, a substance has been introduced to take the place of the older preparations of cannabis indica, and has been used to quiet insane patients in the dose of 1 to 2 grains (0.06–0.12 Gm.), but its effects are not particularly satisfactory.

Other Products.—Although ganja is the practical equivalent of our drug, yet it is used by the natives wholly for smoking, sometimes mixed with tobacco, being entirely too powerful for habitual internal use. It is frequently used for poisoning, resulting in temporary active insanity, followed usually by recovery. The dervishes make an extremely somniferous preparation by boiling the tops in fresh butter or almond oil.

Chur is the mass of small twigs and bracts, rich with particles of resinous matter, which break off during preparation. It is the most powerful form of the cannabis drug.

Churras is the resinous matter removed from the standing plants by various methods. It is practically the active constituent. Prain declares it to be not a resin, or oil, or an oleoresin, but a peculiar substance which oxidizes into resin, like an oil.

Mom Churras (*Churras wax*) is a waxy-looking substance like churras, used in confections.

Bhang is a cheap substitute for tea, used by the poorer classes, made by drying the leaves of the wild plants of both sexes. Its composition and quality are very irregular. There is some question about its being beneficial or harmful, but certainly it possesses no active narcotic properties.

Fructus Cannabis.—*Hempseed*, E.; *Hanfsamen*, G.; *Semenes de chanvre, Chenevis*, Fr.—This is an akene, about 3 Mm. ($\frac{1}{8}$ In.) long, ovate, somewhat flattened, and somewhat 2-edged; the pericarp is thin, hard, smooth, greenish or brownish, delicately veined, and contains a single greenish seed, the embryo of which has the caulicle bent upon one of the cotyledons. The fruit is inodorous, and has an unpleasant, sweetish, and oily taste. By trituration with water it yields an emulsion. It contains 28 to 36 per cent. of a greenish- or brownish-yellow drying fixed oil, and 22 to 24 per cent. of proteid. Hempseed oil is an important commercial product.

CANTHARIS, *U. S.*, *Br.*—Cantharides.

Cantharides, P. G.; *Muscæ Hispanicæ.—Spanish flies*, E.; *Spanische Fliegen, Canthariden, Kanthariden*, G.; *Cantharides*, Fr.; *Cantaride, Cantarella, Mona di Spagna*, It.; *Cantarides*, Sp.

The beetle *Cantharis vesicatoria* (L.) De Geer (*Melæ v.* L., *Lytta v.* Fabricius.—Order *Coleoptera*, thoroughly dried at a temperature not exceeding 40° C. (104° F.).

Cantharis is official in all pharmacopœias, many of which specify that the ash should

not exceed 8 per cent. Many also specify the amount of cantharidin, some at not less than 0.4 per cent., others, 0.5 per cent. The Russian specifies about 8 per cent. of moisture and 9 to 10 per cent. of alcoholic extract, dried at 100° C. (212° F.). The Swiss specifies that they be renewed annually; others, that worm-eaten, yellowish, and broken ones, and those dressed with oil (detected by the greasy stain imparted to paper), and those with a musty or ammoniacal odor, shall be rejected.

Origin.—This beetle is indigenous to southern and central Europe and adjacent Asia, and is collected chiefly in Hungary and southern Russia. It frequents chiefly trees and shrubs of the families *Oleaceæ* and *Caprifoliaceæ*, such as the ash, lilac, elder, and honeysuckle. Its far-reaching, very penetrating, and offensive odor makes its presence known. The insects are collected early in the morning, by spreading cloths under the trees and shrubs, which are then shaken or beaten with poles; the insects are plunged into hot water, afterward spread out and dried. A better method for killing them is by means of chloroform, ether, oil of turpentine, or carbon disulphide, after enclosing them in a tight vessel. Collection is mostly in July, and they reach London and New York by way of Moscow and Hamburg, many in barrels, the finest in paper-lined boxes.

FIG. 77.

Cantharis vesicatoria.

FIG. 78.

Cantharis vittata.

FIG. 79.

Mylabris cichorii.

Description.—The beetle is from 15 to 30 Mm. ($\frac{3}{5}$ to $1\frac{1}{5}$ In.) long and 5 to 8 Mm. ($\frac{1}{5}$ to $\frac{1}{3}$ In.) broad, flattish-cylindrical in shape, of a shining brass- or copper-green color above and below, and finely punctate above. Head obtusely triangular and subcordate, with a longitudinal furrow; eyes 2, lateral; antennæ filiform, of 11 joints, the lowest 3 green, the upper black; thorax of the same width as the head, obtusely quadrangular, longitudinally channelled; wing-cases covering the body, with 2 fine longitudinal ridges; wings ample, membranous, brownish-transparent; tarsi of the hinder legs with 4, and the others with 5, joints; claws bifid. Cantharides have a strong and disagreeable odor and a slight taste, becoming strongly acrid. They yield a brown-gray powder intermixed with green shining particles.

Russian cantharides, of a coppery-green and larger than those of southern Europe, are more highly esteemed.

Constituents.—The active constituent of cantharis is *cantharidin* ($C_{10}H_{12}O_4$), the anhydride or lactone of cantharidic acid ($C_{10}H_{14}O_5$). It crystallizes in colorless prisms and scales without odor or taste, nearly insoluble in cold alcohol, soluble in 500 parts of water, in hot alcohol, ether, chloroform, and fixed and volatile oils. It sublimes at 100° C. (212° F.). Combining with water, it forms cantharidic acid, which with alkalies forms soluble crystallizable salts, the potassium cantharidate dissolving in 25 parts of water. On decomposing these salts with acid, not cantharidic acid, but cantharidin is set free. The yield of cantharidin from *Cantharis vesicatoria* is 0.17 to 1 per cent. (mostly 0.7 to 0.9 per cent.). Other constituents of cantharis are fat, an inert oil soluble in alcohol, yellow viscid matter soluble in water and alcohol, a volatile principle causing the characteristic odor, a yellow substance soluble in ether and alcohol, black extractive, chlorophyll, phosphates of calcium and magnesium, and free formic, acetic, and uric acids.

Preservation.—All blistering beetles should be kept in a well-dried condition and in close vessels, the drying to be effected at a temperature not exceeding 40° C. (104° F.), so as to avoid loss of cantharidin. If they cannot be kept in this condition, they may be protected from the attacks of mites and of small beetles and their larvæ by the addition of a little camphor, ether, chloroform, oil of turpentine, benzene, or carbon disulphide. W. E. Saunders (1883) found the vapor of chloroform to afford better pro-

tection than camphor. The blistering principle resides mainly in the soft parts of cantharides. The idea which has been sometimes advanced, that they increase in strength when thus attacked by insects, is erroneous.

Adulterants and Substitutes.—Cantharides are occasionally mixed with beetles of a similar color which have been collected with them, but evidently not for fraudulent purposes. The shape and color of the insects prevent them from being adulterated. But powdered cantharides is said to be sometimes ground together with euphorbium.

Pharmaceutical Preparations.—Cantharidal Collodion, U. S. P.; Cantharides Cerate, U. S. P.; Cantharides Liniment, N. F.; Cantharides Ointment, Br. P.; Cantharides Paper, N. F.; Tincture of Cantharides, U. S. P.

Action and Uses.—When Spanish beetles are swallowed, they produce intense burning in the throat, stomach, and bowels, with nausea and vomiting, the vomit often becoming black from the presence of blood. Bloody purging may also be developed, and death may soon take place because of the gastro-enteritis and the suppression of the urine by the intense irritation of the kidneys, as these organs endeavor to eliminate the poison. If small poisonous doses are used, the urine becomes scanty and albuminous, and finally bloody. Priapism may result, owing to the intense genital irritation, and in the female this irritation of the genito-urinary tract may result in abortion. Sometimes, as a result of the intense inflammation of the genito-urinary tract, local gangrene results. The smallest fatal dose of cantharides on record is said to be 24 grains (1.56 Gm.), but as abortion complicated the case it is not certain that this is a fatal dose in an ordinarily healthy individual.

Cantharides is employed in medicine internally in very minute doses as a stimulant for the kidneys when these organs are torpid, and also for its stimulant effect on the skin in dry, scaly cutaneous diseases. In incontinence of urine depending upon relaxation of the sphincter of the bladder it may also do good in the dose of 1 to 5 minims (0.05–0.30 Cc.) of the tincture. Externally it is employed for the purpose of producing a blister. Under these circumstances, it is commonly used in the form of cantharidal collodion or cantharides cerate. Each of these preparations usually takes about 5 hours to develop a blister. After they are applied for some time the pain may be modified and the blister increased in size by applying a poultice to the part. Blistering by means of cantharides is indicated wherever a powerful and lasting form of counterirritant is required. The blister itself should never be applied to inflamed skin, as it may cause a slough, and, as a general rule, cantharidal blisters are contraindicated in children because of the nervous irritation which they produce, while in old and feeble persons they may cause obstinate sloughing of the parts to which they are applied. Probably the most useful application of cantharides as a blister is its use at the nape of the neck in threatened effusion at the base of the brain, and upon the precordium in the treatment of pericarditis. Vomiting may sometimes be stopped by putting small blisters over the pneumogastric nerves in the neck or by placing a small blister on the epigastrium.

When irritation of the kidneys is present, a sufficient quantity of cantharides may be absorbed from a blister to increase the renal inflammation. It should therefore be used with caution in this condition.

Poisoning by cantharides is to be treated by the use of an emetic or stomach-pump, if vomiting has not taken place; by the ingestion of mucilaginous or albuminous drinks to protect and soothe the inflamed mucous membrane, and by the use of opium to allay pain and inflammation.

Oils should not be administered, as they aid in the solution and absorption of the poisonous principle of the drug.

Allied Drugs.—The number of beetles possessing similar properties, and known as "blistering beetles," is very large, and some of them have come into use as substitutes for cantharis. Among the American species may be mentioned the following:

Cantharis vittata, or potato-fly, which has a black thorax and wing-cases, with 3 yellow stripes upon the former, and the latter margined with yellow and with a yellow stripe down the middle, and which yields 0.4 to 1.3 per cent. of cantharidin; *C. cinerea*, black, closely punctured, and covered with ash-gray hairs; *C. marginata*, elytra black, with the margin ash-colored; *C. atrata*, only about ⅓ inch long, uniformly black. Attention has also been called to *C. Nuttallii*, which resembles the Spanish fly, but has golden-purple wing-cases striped with green; it is very abundant in Kansas and Colorado. A number of other species of cantharis have also been employed.

Mylabris cichorii Fabricius, and *M. Phalerata* Pallas, two vesicating insects indigenous to

eastern and southern Asia and to some parts of Africa, have been considerably imported as *Chinese blistering-flies;* the insects are black, with 2 orange-colored bands and 2 spots of the same color upon the wing-cases. They yield a blackish-gray powder destitute of the green glossy particles observable in powdered cantharides, and are quite efficient as a vesicant, containing 1 to 1.75 per cent. of cantharidin. Other species of *Mylabris* have also been used.

The East India *Lytta Gigas* Fabricius, which is longer than cantharides, and of a purplish-blue color, has likewise been occasionally met with in commerce. It contains about 0.85 per cent. of cantharidin. *Huechys sanguinaris* is said to contain no cantharidin.

Other Insects Employed in Medicine.—*Blatta orientalis*, the common cockroach, was early employed in medicine. An oily decoction of these insects was used to cure warts, scaly eruptions, indolent ulcers, contusions, boils, etc. Internally, they were given along with resin for the relief of dyspnœa (Pliny). More recently (1878) in Russia they have been employed in *albuminuria*, being said to diminish the quantity of albumin, and to increase perspiration and urine, without impairing the digestion or irritating the kidneys. The daily dose was from 4 to 5 grains (0.25 to 0.30 Gm.) of the powder obtained from the dried insect.

Antihydropin, a crystalline principle derived from the cockroach, has also been employed as a diuretic. The dose is from 3 to 5 grains (0.20–0.30 Gm.) four times daily.

Ænas Afer, a coleopterous insect that abounds in Spain, is claimed to possess over cantharides the following advantages: it is cheaper; it acts without appreciable pain; it is equally powerful, and does not irritate the urinary organs (*British Med. Jour.*, May 20, 1882).

Red ants were formerly used medicinally. A large number of them, enclosed in a linen bag, were infused in boiling water, which, with the bag, was then added to local or general baths in the treatment of chronic gout or rheumatism. The affected foot or hand was sometimes subjected for several hours to the action of the ants by being thrust into their hills. Internally, a tincture of domestic manufacture was given, and which was made by the prolonged infusion of a large amount of ants in an equal quantity of brandy. An official *spiritus formicarum* was formerly in common use, and was retained in the German Pharmacopœia for 1901. It was given internally, in doses of from 20 to 50 drops, in nervous and paralytic affections, and also applied by friction. An oil made by macerating living ants in almond oil was used for similar external purposes. A preparation of ants is said to constitute an important ingredient of some of the African arrow poisons.

CAPPARIDACEÆ.—The Caper Family.

Genera, 33; species more than 300; mostly of tropical and warm-temperate regions. They are closely related in all ways to the *Cruciferæ*, the well-known condiment capers showing this relationship in its pungent constituents, similar to those of the mustards.

Caper, Capers, or *Capparis* (*Kapper*, G.; *Caprier*, Fr.; *Alcaparro*, Sp.) consists of the unopened buds of *Capparis spinosa* L., suitably preserved in salt and vinegar. The plant is a spiny shrub of the eastern Mediterranean and adjacent regions, and is largely cultivated for this product. Leaves, bark, and seeds possess a bitter and somewhat acrid taste. The buds are roundish-oval, about ¼ inch in diameter, of a greenish color and an aromatic and pungent taste, reminding one of cresses. Upon dissection, they exhibit 4 sepals and 4 petals, numerous stamens, and a stalked ovary. Their important constituent is a volatile oil of an alliaceous odor. They also contain the yellow coloring-matter *rutin* (see RUTA). Their properties are mildly stimulant, stomachic, and antiscorbutic. The root-bark contains a saponin-like body, tannin, and an amaroid.

The genus CAPPARIS L. contains more than 150 species, of the warmer parts of both hemispheres, and a number of them are credited with similar, or even more pungent properties than those of *Caper*. The root-barks of *C. Jamaicensis* Jacq. (*C. cynophallophora* L.), *C. ferruginea* L., and of other species possess blistering properties, and, taken internally, are diuretic. All parts of the plants are reported antispasmodic and anthelmintic and the fruits antiscorbutic. The fruits of *C. Lodado* R. Br. and of other species are used in Africa as pepper-substitutes. Many species of *Cratæva* are similarly employed for their pungent properties, the bark of *C. Gynandra* L. (*Guaco*) of the West Indies, and of other species in both hemispheres, being used as antiperiodics and externally as rubefacients. A number of these have edible fruits. The fruits of a South American species have been utilized as an antispasmodic in epilepsy under the coined name of *Simulo*, this drug being at the same time referred to *Capparis coriacea* Burm. or to *C. oleoides*. In India, the entire plant of *Cleome viscosa* L. (*Polanisia v.* DC.; *Capparis isonandria* L.—known in the Philippines by the Tagalog name *Balabalanoyan* or *Apoyapoyan*) is used as a rubefacient, and the seeds as a mustard substitute. The same use is made of the seeds of the East Indian *Gynandropsis pentaphylla* DC. The seeds of *Cleome Chelidonii* L. (*Polanisia C.* DC.—*Kanthootee*), of India, are used as an anthelmintic, as are those of several other species. The hairs of *C. pruriens* Tr. et Pl., of Brazil, are irritant, like cowhage.

RESEDACEÆ.—The closely related family *Resedaceæ*, of half a dozen genera, and less than a dozen species, yields several medicinal plants, reminding us in their properties of the mustards and the capparids. The root of *Reseda luteola* L. (*Dyers' weed, Weld*, E. ; *Wau, Gelbkraut, Harnkraut*, G. ; *Herbe jaune, Gaude*, Fr.), of Europe, has the odor and taste of radish. The herbage is bitter and contains *luteolin* ($C_{20}H_{14}O_8$), occurring in yellow silky volatile needles of a faintly bitter and slightly astringent taste, sparingly soluble in water and ether, more soluble in alcohol ; acetate of lead precipitates it yellow, and ferric chloride is colored by it green, and afterward red-brown. Fused with potassium hydroxide, it yields phloroglucin and protocatechuic acid. The seeds contain a green drying oil. Dyer's weed is used to some extent in the arts as a dye-product. In medicine, it was formerly employed as a diuretic and diaphoretic, but its use has been discontinued.

The root of the common garden *Mignonette* (*R. odorata* L.) contains a pungent principle almost identical with the volatile oil of mustard. Mignonette is practically never employed in medicine.

CAPRIFOLIACEÆ.—The Elderberry or Honeysuckle Family.

Genera about 10, species about 300, chiefly shrubs, growing in the north temperate zone or extending into high and cool tropical regions. Many of them are very ornamental, and some are among our favorite decorative shrubs. Besides the VIBURNUMS and SAMBUCUS, elsewhere treated, a number have found more or less important uses in medicine, but they exhibit but little uniformity in composition or properties. *Triosteum* (*Fever-root* or *Fever-wort, White* or *Horse gentian* or *Ginseng, Bastard* or *Wild ipecac, Tinkers'-weed, Wild coffee*, E. ; *Dreisteinwurzel*, G. ; *Trioste*, Fr.) is the rhizome and root of *Triosteum perfoliatum* L. and probably also *T. aurantiacum* Bicknell. They are erect perennial herbs, the stems growing erect, in clusters, to a height of 5 to 12 M. (1½ to 4 Ft.), clammy-hairy, the large opposite leaves ranging from oblong-lanceolate to broadly oval, acuminate and acute, and narrowed at the base. The purplish-green flowers are sessile in axillary clusters, 5-merous, the calyx-teeth superior, long-linear, persistent, the corolla more or less bell-shaped or funnel-shaped, gibbous, and with an oblique and unequally lobed mouth. The 5 stamens, with long anthers and short filaments, are adherent to the corolla-tube. The orange or scarlet fleshy fruit contains usually 3 stones. The first-named species has the leaves distinctly connate in pairs, and the leaves are usually broader than in the other, in which there is little or no cohesion of the leaf-bases. The plants grow in rich woodlands or shaded locations, especially in rocky soil, in the southeastern and central United States. *T. angustifolium* L. has yellow or yellowish flowers and rougher and thicker leaves, and doubtless has also yielded a portion of the drug. The rhizome of Triosteum is 15 to 30 Cm. (6 to 12 In.) long, and about 18 Mm. (¾ In.) thick, knotty-cylindrical, sometimes branched, bearing numerous cup-shaped scars, about one-third of its breadth, upon the upper surface, and numerous coarse spreading roots about 12 to 25 Cm. (5 to 10 In.) long, chiefly on the lower side. Externally, the surface is yellowish-brown and more or less longitudinally wrinkled. The fracture of the rhizome is rather hard and tough, the color whitish, the bark thin, the wood with fine medullary rays. The odor is slight after drying, and the taste is characteristic and disagreeable. Little is known of its constituents, except that there is a small amount of the alkaloid *triosteine*. The seeds of this plant when roasted have been employed as a substitute for coffee. The fresh root has been given as an emetic, and in doses of from 20 grains to 1 drachm (1.3–3.9 Gm.) it acts as a cathartic. The emetic properties of the drug appear to reside in its alkaloid *triosteine*. The leaves are said to be diuretic and diaphoretic. The drug has been employed during convalescence from the low fevers, in hysteria and hypochondria, in intermittent fever, and in chronic rheumatism. It is not commonly given as an emetic, but may be used as a substitute for ipecac.

A dozen or more of the hundred species of *Lonicera* or *Honeysuckle* are used medicinally, the fruits generally having emetico-cathartic properties. Several of these drugs have more than a local repute. The herbage of *L. Caprifolium* L. (*Italian honeysuckle* or *Woodbine, Geisblatt, Chevrefeuille*), of southern and central Europe, cultivated for ornament, is used as a cutaneous and mucous tonic and vulnerary, and the seeds as a diuretic. *L. Periclymenum* L. (*English honeysuckle* or *Eglantine, Waldwinde*) is used similarly, and the stems as a substitute or adulterant for dulcamara. *L. brachypoda repens* is used in Japan as a drastic. *L. Japonica* Thunb. is sold in China as *Kin-yin-kwa ; L. Xylosteum* L. as *Jin-tung* or *Kin-yin-kwa.*

Diervilla, the *Bush honeysuckle*, especially *D. Diervilla* (L.) Mac. M. (*Lonicera* D., L.; *D. trifida* Moench ; *D. Canadensis* W.), has a similar repute, especially as a diuretic, and as an application to relieve itching. *D. Japonica* DC. (*Weigelia J.* Thunb.) is reputed poisonous.

Various species of *Symphoricarpus* (*Snowberry, Wax-berry, Coral-berry, Indian currant, Snap-berry, Turkey-berry, Wolf-berry*), of North America, are similary employed.

CAPSICUM, *U. S.*—Capsicum.

Capsici fructus, Br.; *Fructus capsici*, P. G.; *Piper Hispanicum, Bird pepper, Capsicum fruit, Cayenne (African or Pod) pepper, Spur pepper*, E.; *Spanischer Pfeffer, Schlotenpfeffer*, G.; *Capcique, Piment des jardins, Piment rouge. Poivre de Cayenne, P. de Espagne*, Fr.; *Aji, Chile, Pimiento*, Sp.; *Chile de Arvol (de Pajaro, Pequen, Unque, Mirasol)*, Mex.; *Pimiento dido de Dame, P. Pitango, P. Malagueti*, Bras.

The dried ripe fruit of *Capsicum fastigiatum* Blume (*C. minimum* Roxb.—Fam. *Solanaceæ*), deprived of its calyx.

Capsicum is official in nearly all pharmacopœias, though the latter differ greatly in the botanical names used and in the variety specified thereby, and by their descriptions.

Origin.—The cultivated varieties and forms of capsicum are innumerable. They vary in size from that of a cherry to twice the size of a man's fist, in form from spherical, through all ovoid forms, to horn-shaped, from nearly solid to greatly inflated, and through various shades of yellow and orange to scarlet or purplish-crimson. The plants are herbaceous and annual, or shrubby, and that which is annual in one climate may be perennial in a warmer one. They have been attentively studied by many able botanists, and the number of the species proposed reaches up to nearly a hundred, while by the latest classification (*Irish, Mo. Bot. Gard.*, 1898) they have been reduced to two, and the author has not been able to specify any character by which these can be distinguished. Under such circumstances, name-specification is of little value, and, since the varieties differ greatly in quality, the official description becomes our best reliance. The variety adopted in our pharmacopœia is undoubtedly the most active one available for medicinal use. Its nativity is not known with certainty, but is probably tropical America. It is now very widely cultivated in warm countries, but our supplies come chiefly from India and Africa, where the plant is fully naturalized.

Fig. 80.

Capsicum, slightly enlarged.

Description.—From 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) long and usually about one-third as broad, oblong-ovoid, somewhat flattened, obtuse, covered with a scarlet or crimson, shining, translucent, wrinkled, coriaceous epicarp, through which the seeds are more or less visible; 2-celled and containing about 20 yellow, flat, reniform seeds, which are pointed at one end, about 3.5 Mm. ($\frac{1}{7}$ In.) long and 2.5 Mm. ($\frac{1}{10}$ In.) broad, and attached to a thin central placenta; odor characteristic, pleasant; taste intensely pungent and acrid. Not more than 7 per cent. of ash should be yielded. As viewed under the microscope, the powder exhibits characteristic epidermal cells, which are almost isodiametric on superficial view, and have greatly thickened and folded inner walls; collenchyma-cells from the hypoderm, and the absence of starch-grains and sclerenchymatous fibres are also characteristic.

Constituents.—The active principle appears to be 0.02 per cent. of *capsaicin* ($C_9H_{14}O_2$), found only in the inner portions, and occurring in colorless, very pungent crystals, soluble in alcohol, ether, fixed oils, and alkalies, but slowly soluble in turpentine, and very slightly in water. Capsaicin melts at 59° C. (138.2° F.), and volatilizes at 115° C. (239° F.) with very irritating vapors. Its pungency is destroyed by oxidation. Norbitz (1897) isolated 0.05 to 0.07 per cent. of crystalline *capsacutin*, which is neither alkaloid, glucoside, nor acid, and imparts a pungent taste to 11,000,000 times its weight of water. *Capsicin*, a thick yellowish-red liquid, slightly soluble in water, and *capsicol*, a red oily liquid, are oleoresinous mixtures containing the active principle. The other constituents are a volatile, non-acrid alkaloid, resembling coniine in odor, red coloring-matter, wax, resin, fixed oil, oleic, palmitic, and stearic acids, and a minute quantity of volatile oil with parsley odor.

Adulteration and Substitution.—Entire capsicum is very frequently substituted by other and larger varieties, especially *Paprika* (C. *annuum* L., official in the P. G.), and these are also very commonly ground for or with it. Their description is unnecessary, since anything not conforming to the above description should be rejected. The powdered article is enormously adulterated with other substances, such as damaged flour, corn meal, and even sawdust, these substances being often colored for the purpose. So extensive is this adulteration sometimes, that a quantity of the article may be chewed and swallowed without discomfort. Besides making a microscopical examination and an incineration, it is well to determine the amounts of oleoresin (see Oleoresina Capsici), of which there should be at least 5 per cent.

Pharmaceutical Preparations.—Fluidextract of Capsicum, U. S. P.; Oleoresin of Capsicum, U. S. P.; Tincture of Capsicum, U. S. P.; Tincture of Capsicum and Myrrh, N. F.

Action and Uses.—When applied to the skin, capsicum acts as a powerful rubefacient, and when placed in contact with mucous membranes produces vesication. Administered internally, it causes a feeling of warmth in the stomach, increases the appetite, and produces a sensation of heat over the entire body. The drug is thought by some to be a circulatory stimulant, but as such it is not commonly employed. If given internally for a long time, it may cause chronic gastritis attended with dull pain over the region of the liver and stomach; and if a very large amount is given at one time, it may produce acute gastritis with renal inflammation and strangury.

Capsicum is largely employed as a condiment, and lends itself to the control of flatulence induced by the eating of certain vegetables. It is one of the best remedies we can employ in the treatment of atonic dyspepsia, chronic alcoholism, and in delirium tremens, provided, however, that in the latter condition the stomach is not too irritable. In acute alcoholism, after the lapse of a few days, it is also given with benefit. Capsicum is largely given combined with other remedies, such as calomel and quinine, to aid in their absorption and increase their efficacy. It has been employed in the flatulent colic of the aged, relieving the pain and preventing the flatulence, and has been recommended as a stimulant in the low fevers. It is believed by some to be beneficial in the treatment of the intermittent fevers. The drug is thought to be a good remedy in chronic nephritis, as it decreases albuminuria, but it should not be given if acute nephritis is present. As a gargle, equal parts of the tincture of capsicum and glycerin may be employed in simple tonsillitis, pharyngitis, and relaxed uvula. A decoction made by boiling 1 ounce (30 Gm.) of powdered pepper, ½ ounce (16 Gm.) of table salt in 8 ounces (240 Cc.) each of vinegar and water, was formerly recommended in tablespoonful doses as a gargle in the treatment of malignant scarlatina. The tincture has been locally applied in the treatment of chilblains, and the capsicum plaster may be successfully employed for superficial neuralgia, muscular rheumatism, and lumbago.

The dose of powdered capsicum is from 5 to 10 grains (0.30–0.60 Gm.); of the tincture, from 5 to 10 minims (0.30–0.60 Cc.); of the oleoresin, from ¼ to ½ grain (0.015–0.03 Gm.).

CARBO ANIMALIS, *U. S.*—Animal Charcoal.

Carbo ossium, Ebur ustum, Spodium.—Boneblack, Ivoryblack, E.; *Charbon animal, Noir d'os*, Fr.; *Thierkohle, Knochenkohle, Beinschwarz*, G.; *Carbone animale, Nero di ossa*, It.; *Carbon de hueso*, Sp.

Charcoal prepared from bone. It is no longer official in the British Pharmacopœia.

Preparation.—Boneblack of commerce is obtained by roasting bones deprived of fat in iron cylinders until vapors cease to be given off, when charcoal is left intimately mixed with about 10 times its weight of the inorganic constituents of bone, and containing a little nitrogen, probably as nitrogen carburet. The volatile products of the dry distillation are various gases, an ammoniacal aqueous liquid called *bone-spirit*, and a blackish-brown tar called *bone-oil*.

Carbo carnis, or meat charcoal, is prepared by cutting into small pieces 3 parts of veal freed from fat, mixing it with 1 part of small bones, and roasting in a covered vessel until inflammable vapors cease to escape; the residue when cold is powdered.

Properties.—Boneblack is a dull-black, rather dense, inodorous, and rather tasteless mass, which for uses in the arts is either granulated or powdered. It is entirely insoluble in all simple solvents; hydrochloric acid dissolves a portion of the boneblack; the compounds removed are the inorganic constituents of the bones, which consist mainly of calcium phosphate, with some calcium carbonate and magnesium compounds. When ignited with free access of air, boneblack leaves a white ash, amounting to at least 85 per cent. of the original weight, which should be completely soluble in hydrochloric acid with the aid of heat. Boneblack has the remarkable property of removing organic coloring-matters from their neutral or somewhat acid solutions, and is employed for that purpose in the refining of sugar and in many chemical operations, for many of which its previous purification is requisite to avoid contamination with earthy matters, which would be dissolved by the organic acids.

Carbo Animalis Purificatus, U. S.— *Purified animal charcoal,* E.; *Charbon animal purifié,* Fr.; *Gereinigte Knochenkohle,* G.—Animal charcoal, in No. 60 powder, 100 Gm.; hydrochloric acid, 300 Gm.; boiling water, a sufficient quantity. Introduce the animal charcoal into a capacious flask, add 200 Gm. of hydrochloric acid and 400 Cc. of boiling water, and connect the flask with an upright condenser. By means of a sand-bath keep the mixture gently boiling during 8 hours. Then add 500 Cc. of boiling water, transfer the mixture to a muslin strainer, and when the liquid has run off return the charcoal to the flask. Add to it 100 Gm. of hydrochloric acid and 200 Cc. of boiling water, boil for 2 hours, again add 500 Cc. of boiling water, transfer the whole to a plain filter, and, when the liquid has run off, wash the residue with boiling water until the washings give only a faint cloudiness with silver nitrate test-solution. Dry the powder in a drying-oven and immediately transfer it to well-stoppered vials.—U. S.

Properties.—The physical properties of purified animal charcoal are the same as those of boneblack already described. If 2 Gm. of the powder be ignited at a red heat, with free access of air, in a broad, shallow porcelain or platinum dish, it should not leave a residue weighing more than 0.08 Gm. or 4 per cent. of the original weight (limit of silicates and other fixed inorganic matter). If 1 Gm. be boiled with a mixture of 3 Cc. of potassium hydroxide test-solution and 5 Cc. of water for several minutes, the filtrate should be colorless (evidence of complete carbonization).—U. S.

Purified animal charcoal removes from their aqueous solutions tannin, alkaloids, bitter principles, basic lead and other metallic salts, iodine, lime, etc.—a property which it shares more or less with boneblack, and which was first observed by Figuier (1810). This property is due to the finely divided state of the carbon and the surface-attraction resulting therefrom, and may be imparted to wood charcoal if, previous to charring, the vegetable substances are intimately mixed with flint, lime, or other earthy matters; a mixture of 10 parts of pipe-clay, 50 parts of finely powdered coal, and 2 of tar, yields, after carbonization, a charcoal possessing excellent decolorizing properties, depending in part upon the presence of alumina. By reheating purified animal charcoal with potassium carbonate, its decolorizing power, which was impaired by the treatment with acid, is greatly increased; and similar active charcoals are obtained from blood, horn, leather, etc., by mixing them with the salt mentioned, carbonizing the mixtures, and exhausting the residues with water.

The value of animal charcoal as a decolorizer is best ascertained by treating known weights of it with diluted solutions of indigo or litmus, and ascertaining the bulk which may be completely decolorized by slow percolation. Corenwinder (1853) proposed treatment of the charcoal with diluted solutions of lime and sugar, and determining by titration the amount of lime remaining in solution. The decolorizing property, however, does not appear to be strictly proportional to the lime- or salt-absorbing power of animal charcoal. When the decolorizing power of the charcoal has been exhausted, it cannot be restored by heating to redness, because a dense charcoal, resulting from the absorbed substances, will then be deposited in the pores; but if allowed to ferment, this substance will be destroyed, and by washing the charcoal with water, drying, and igniting, it becomes again a good decolorizer. Pelouze (1854) proposed to effect the revivification of spent animal charcoal by treating it with caustic alkalies or alkaline carbonates; according to Renner (1862), the process is a tedious one. Placing the decolorizing power of boneblack = 1, Bussy ascertained that of purified animal charcoal to be = 1.6; purified animal charcoal ignited with potassium carbonate = 20; blood ignited with potassium (or calcium) carbonate = 20; glue ignited with potassium carbonate = 15.5.

In purifying solutions by charcoal, loss of the principal constituent is often experienced from absorption in the charcoal.

Action and Uses.—Animal charcoal, either in its crude or purified state, is rarely employed in medicine. The purified animal charcoal has been proposed as an antidote for poisonous vegetable alkaloids, ½ ounce (16 Gm.) of charcoal to be used for each grain of alkaloid ingested.

CARBO LIGNI, *U. S.*, *Br.*—Charcoal.

Carbo ligni pulveratus, P. G.; *Carbo præparatus, Carbo e ligno, Carbo vegetabilis.*—*Wood charcoal*, E.; *Charbon végétal*, Fr.; *Holzkohle, Präparirte Kohle*, G.; *Carbone di legno*, It.; *Carbone vegetal*, Sp.

Charcoal prepared from soft wood and very finely powdered.—U. S.

Preparation.—Wood heated to about 300° C. (572° F.) leaves charcoal as a residue. On a large scale this is effected in iron retorts, in closed chambers of brick, or by the method of pile-burning, in which the heat developed by the combustion of a portion of the wood effects the charring of the rest. Two, and sometimes three, stacks of billets of wood of even length are piled up around stakes driven into the ground until a flattish cone of from 30 to 70 feet in diameter has been formed, which is covered by sod and earth, an opening being left at the top for the escape of the water which is first expelled, and several at the base. After the heap has been kindled in the center the top opening is closed, and when the wood has become perfectly dry the open spaces at the base are likewise closed and the pile left to smoulder for several weeks. The charcoal is finally withdrawn and extinguished by water, dry sand, or charcoal-dust. The yield varies with the kind and dryness of the wood. Karsten found that a wood which lost at 100° C. (212° F.) 57 per cent. and at 150° C. (302° F.) an additional 10 per cent. of its weight, would yield only 14 per cent. of charcoal, while the same wood dried yielded 25 per cent. The difference is explained by the formation of carburetted hydrogen on the passing of aqueous vapors over red-hot charcoal, and the same cause accounts for the smaller yield in the dry distillation of wood when the cylinders are rapidly heated, so that the wood near the iron is charred, while the pieces in the center still contain water.

Properties.—Charcoal has the shape and shows the texture of the wood from which it was obtained; it is black, inodorous, tasteless, very porous and brittle, insoluble and infusible. Alcohol in which charcoal has been digested should not become colored, and on evaporation should leave no residue. When charcoal is heated in the air, it is converted into carbon monoxide or dioxide, but it should not burn with flame (absence of organic compounds). Ordinary wood charcoal is usually incompletely carbonized, and requires to be again ignited in nearly closed vessels until it ceases to give off inflammable vapors, and to be reduced to a uniform, fine, non-gritty, dull-black powder before it is adapted for medicinal use. If 1 Gm. of charcoal be boiled with a mixture of 3 Cc. of potassium hydroxide test-solution and 5 Cc. of water for several minutes, the filtrate should be colorless or nearly so (evidence of complete carbonization).—U. S. Prepared by pile-burning, charcoal is considerably denser than when obtained in retorts; the latter kind is therefore preferable, particularly that made from soft wood, which is more porous than that obtained from hard wood. Charcoal made from young shoots of the willow, poplar, or linden is for these reasons most esteemed. It contains the inorganic constituents present in the wood, and these amount in well-prepared charcoal to about 1 per cent. The Br. allows 7.5 per cent. of ash.

Like other porous bodies, wood charcoal possesses the property of absorbing gases; this was observed first (1777) by Fontana and by Scheele, and Lowitz (1785) discovered the clarifying and decolorizing property of wood charcoal, in consequence of which it was used in the refining of sugar until animal charcoal was found to be better adapted for this purpose. The volumes of gases absorbed by recently ignited wood charcoal are not uniform, but vary with the nature of the gas and of the charcoal, as was shown by Morozzo (1783), the absorbing power being for oxygen 10, for carbon dioxide 35, for hydrogen sulphide 55, and for ammonia about 100 volumes, to 1 of the charcoal. Considerable heat is generated thereby, as also by the oxidation of some of the gases by the absorbed oxygen, and may increase to spontaneous ignition; and the increase in weight of pile-burned charcoal may amount to from 10 to 15 per cent. by absorption of watery vapors. This property explains the uses of charcoal as a deodorizer, for which purpose it should be freshly burned or reheated to expel the gases condensed in its pores. Odorous principles are not only absorbed by it from the atmosphere, but likewise from solutions in water and weak alcohol; its employment for the removal of the fusel oil from spirits is well known (see Alcohol). It acts in a manner similar to animal charcoal in precipitating from their aqueous solutions metallic salts, or even the metals, most bitter principles, and coloring-matters; but for the latter purpose is much inferior to the former.

Composition.—Wood charcoal is amorphous carbon mixed with inorganic constituents of the wood from which it has been prepared. If insufficiently burned, it is also contaminated with empyreumatic products resulting from partial decomposition of the organic principles.

Action and Uses.—Charcoal is a desiccant, and because of the fact that its interstices contain large quantities of oxygen, it possesses the property of oxidizing putrefactive organic matter, hence its employment as a disinfectant and deodorant. It also inhibits the growth of micro-organisms by depriving them of their normal amount of moisture. Internally it has been employed in fermentative dyspepsia with eructations, and in subacute gastric catarrh and in gastralgia. Its administration is also beneficial in the treatment of fermentative diarrhœas, but it is sometimes employed also as a useful laxative when the bowels are confined. Externally in the form of a poultice made with bread-crumb, linseed meal, and boiling water, it is applied to foul ulcers and gangrenous sores as a deodorant and emollient. Charcoal has also been largely employed as a filtering medium for the purpose of purifying water. It may be given in the form of a fine powder in the dose of from 1 to 4 drachms (4-16 Gm.) or more; or it may be taken in the form of lozenges or biscuits containing 20 per cent. of the drug. When taken internally it should be as freshly prepared as possible.

CARBONEI DISULPHIDUM, *U. S.*—Carbon Disulphide.

Carbonis Bisulphidum, Br.; *Alcohol sulfuris, Carbonei bisulphidum. Carbon bisulphide*, E.; *Sulfure de carbone*, Fr.; *Schwefelkohlenstoff, Schwefel-alkohol, Kohlensulfid*, G.; *Sulfuro di carbonio*, It.

Formula, CS_2. Molecular weight, 75.57.

Origin.—Scheele (1777) noticed the production of a very fetid gas on heating a mixture of sulphur and charcoal, but Lampadius (1796) by accident first obtained the compound in a liquid state. Clément and Désormes (1802) elaborated a process for its preparation, and stated it to be a compound of carbon and sulphur; its exact composition, however, was first proved by Vauquelin (1811) and by Berzelius (1812).

Preparation.—Carbon disulphide is made on the large scale by heating in a cylinder fragments of charcoal or coke to redness, and adding through a tube, near the bottom, pieces of sulphur, which is vaporized and unites with the red-hot charcoal. The condensed liquid contains sulphur in solution, from which it is freed by distillation on a water-bath, and the compounds having a disagreeable odor are removed by prolonged agitation with milk of lime, litharge, chlorinated lime, powdered corrosive sublimate, or copper sulphate, decanting, adding about 2 per cent. of a bland fixed oil or beeswax, and rectifying on a water-bath. E. Allary (1881) uses for the same purpose water and potassium permanganate, the latter added in small quantities, until after agitation the liquid retains its violet color; redistillation is not necessary. Carbon disulphide should be kept in well-stoppered bottles in a cool place, remote from lights or fire.

Properties.—Thus obtained, it is a very mobile colorless liquid having a high refracting power, and when pure a rather agreeable ethereal odor, and a pungent, aromatic, and cooling taste; but often it is of a more or less fetid odor from the presence of other volatile compounds. It has the specific gravity 1.290 at 0° C. (32° F.) and 1.256 to 1.257 at 25° C. (77° F.).—U. S. It boils at 46° or 47° C. (114.8° or 116.6 F.).—U. S. It evaporates rapidly at the ordinary temperature, and partly congeals on passing a rapid current of dry air over its surface. It is very inflammable—more so than ether—and burns with a blue flame, yielding sulphur dioxide and carbon dioxide or monoxide. The temperatue of a burning cigar will ignite it. It is soluble in 526 parts of water at 25° C. (77° F.), and in almost all proportions of absolute alcohol, ether, chloroform, and fixed and volatile oils, and in 1½ to 2 parts of official alcohol. It dissolves freely phosphorus, sulphur, bromine, iodine, fats, volatile oils, caoutchouc, and other compounds, and unites with some of the sulphur bases, forming *sulphocarbonates*, which correspond to the carbonates, containing sulphur in place of oxygen. Dissolved in alcohol and heated in the presence of ammonia, *ammonium sulphocyanate* and hydrogen sulphide are produced: $CS_2 + 2NH_3$ yields $NH_4CNS + H_2S$.

Tests.—Carbon disulphide should not change the color of moistened litmus-paper (absence of sulphurous acid), and when agitated with solution of lead acetate should not produce a brown or black color (absence of hydrogen sulphide). A portion evaporated

spontaneously in a glass or porcelain vessel should leave no solid residue (absence of sulphur).

Action and Uses.—Carbon disulphide is said to be both a general and a local anæsthetic, also rubefacient, antiseptic, and anodyne. Because of its disagreeable odor, however, it is rarely employed in medicine at the present time. It is largely used in the arts, and workmen when exposed to the vapor suffer from headache, vertigo, and talkative delirium. If the exposure is continued sufficiently long, it induces paralysis, with impairment of sight, hearing, and appetite. When taken internally in overdose, it acts as a powerful narcotic poison, producing deep sleep followed by coma, a running, rapid, feeble pulse, stertorous respiration, complete loss of reflex action, a cold, clammy sweat, and subnormal temperature, followed by death. A solution of 1 in 300 is said to destroy micro-organisms, and for this reason it was formerly heralded as a remedy for enteric fever, but its administration was not attended with success. When locally applied, it may give some benefit in facial and intercostal neuralgias, in sciatica, and in toothache. When applied to the spine, it is said to relieve the lancinating pain of tabes dorsalis. Its local application is also stated to reduce lymphatic enlargements and syphilitic tumors, but it is probably of little benefit in these conditions. The internal dose is stated to be from 5 to 15 minims (0.3–1 Cc.), largely diluted with water, 4 or 5 times daily.

In the arts it is largely employed for the extraction of fats and in the vulcanization of caoutchouc, and has been proposed as a solvent for obtaining the delicate perfumes of flowers. It should be kept in *cork-stoppered* bottles, away from flame and in a cool place.

CARBONEUM—Carbon.

Carbone, Fr.; *Kohlenstoff*, G.; *Carbonio*, It.; *Carbon*, Sp.

Symbol, C. Atomic weight, 11.91. Quadrivalent and in a few instances bivalent.

Carbon is very abundantly diffused in nature, and is one of the most essential elements. It occurs combined in all vegetable and animal organisms and in the products of their activity; and it was for this reason that compounds of carbon early came to be treated as a separate branch of chemistry, which was called "Organic Chemistry." In the mineral kingdom, it occurs both free and combined: combined, it occurs mainly as carbon dioxide and its salts, the carbonates, and in the hydrocarbons (hydrogen and carbon), which exist in such great quantities as petroleum and natural gas; in the free state, carbon occurs as diamond, which is the purest form, and more or less impure as graphite and the different varieties of amorphous carbon, such as coal, coke, charcoal, etc.

There are 3 allotropic varieties of carbon, two being crystallized, namely, diamond and graphite, the other being amorphous, as coal, charcoal, etc.

1. Diamond is found chiefly in India, near Golconda, Borneo, South Africa, and Brazil, and is in colorless and variously colored octahedrons of 3.5 to 3.6 specific gravity. It is a non-conductor of electricity and the hardest substance known. Lavoisier proved it to be pure carbon; when burned, it usually leaves between 0.05 and 0.2 per cent. of ash; amorphous diamond, which is used for polishing the crystalline variety, may leave up to 2 per cent. The value of crude diamonds exported in 1881 from the Cape of Good Hope was estimated to exceed £4,500,000. H. Moissan, of Paris, has succeeded in preparing diamonds by dissolving carbon in iron at the temperature of the electric arc, about 2500° C. (4532° F.), and suddenly cooling the surface of the iron, whereby the carbon crystallizes out in the interior under great pressure, forming diamonds.

2. Graphite, Plumbago, or Black Lead (*Plombagine, Crayon noir*, Fr.; *Wasserblei, Reissblei*, G.), has been found in many countries, crystallizes in hexagonal plates varying in specific gravity between 1.8 and 2.5, is of a black-gray color, unctuous to the touch, quite soft, and a good conductor of electricity, and leaves between 0.2 and 5 per cent., occasionally even as much as 46 per cent. of ash.

3. Amorphous Carbon exists in nature as *coal*, of which there are three principal varieties—namely, *lignite, bituminous coal*, and *anthracite* (lithanthrax)—which contain respectively about 66, 80, and 90 per cent. of carbon, partly in the form of organic compounds. Artificially prepared, it constitutes *wood charcoal, animal charcoal, coke*, and *lampblack*, the latter being obtained by the incomplete combustion of resinous matters; after it has been heated in covered vessels to expel the volatile organic compounds it constitutes a nearly pure carbon. Coke is the residue left from the dry distil-

lation of coal, and consists of amorphous carbon contaminated with the mineral constituents of the coal.

Oxides of Carbon.—There are two oxides of carbon, the monoxide, CO, and the dioxide, CO_2. The latter has been discussed under Acida. It is formed when carbon or any combustible carbon compound is burned with free access of air. *Carbon monoxide* is formed when carbon is burned in a limited supply of air, as in a grate; in the pure state when chloroform is treated with concentrated potassium hydroxide: $CCl_3H + 3KOH = CO + 3KCl + 2H_2O$; also by the action of cold concentrated sulphuric acid on potassium cyanide, or by warming absolute sulphuric acid with citric acid dried at 150° C. (302° F.). A mixture of CO and H, so-called *water-gas*, is formed when steam is passed through highly heated carbon. Carbon monoxide is a colorless, odorless, poisonous gas, of density 0.9672 (air = 1), and practically insoluble in water. The carbon in this gas has apparently a valence of 2, and this is one of the very few compounds in which carbon shows a valence different from the usual quadrivalence. Carbon monoxide shows some chemical activity. It unites with molten alkalies to form formates, also with metallic potassium and nickel. It burns forming carbon dioxide. Strong interest attaches to carbon monoxide, from the medical point of view, because of its affinity for the hæmoglobin of the blood, which is the cause of its highly poisonous character. Air becomes poisonous when it contains 0.05 per cent. of this oxide.

CARDAMOMUM, *U. S.*—Cardamom.

Cardamomi semina, Br.; *Fructus (semen) Cardamomi (minoris)*, P. G.; *Cardamomum minus (s. Malabaricum).—Malabar cardamoms*, E.; *Cardamomen, Kleine Kardamomen*, G.; *Cardamomes*, Fr.; *Cardamomo menor*, Sp.

The dried nearly ripe fruit of *Elettaria repens* (Sonnerat) Baillon (*Amomum r.* Sonn.; *Elettaria Cardamomum* Maton; *Alpinia C.* Roxb.; *Amomum C.* White; *Matonia C.* Smith; *Renealmia C.* Roscoe.—Fam. *Zingiberaceæ*).

Official in nearly all pharmacopœias.

Origin.—A perennial, reed-like plant of India, where, as in other tropical regions of the Old World, it is very extensively cultivated, requiring rich soil, partial shade,

FIG. 81.

Malabar cardamom.

FIG. 82.

Malabar cardamom seed (× 5).

FIG. 83.

Mysore cardamom seed: transverse and longitudinal section (× 6).

and much experience to insure success. In an experimental or desultory way, it has also been grown in Jamaica and some other parts of tropical America. The most extensive products are those of Ceylon, being not far from three-quarters of a million pounds annually. Of these, the Mysores are preferred, the Malabars, almost identical but a little smaller, coming next, and greatly predominating in amount. The latter are required by the P. G. Ceylon also exports some wild fruits, known as *Ceylons*, of somewhat different properties from those of the cultivated, and the oil distinct. Third in value are the Mangalore fruits, of Madras. Their production is declining. Dr. Henry gives the combined product of Cochin, Annam, and Tonking (*Siam cardamom*) for 1895, as upward of 200,000 pounds. Mysore and Malabar cardamoms alone are included in our official description.

The plant grows in tufts, like a small bamboo, and produces the fruits upon long scapes, which are prostrate among the stem-bases. The fruits are gathered slightly before maturing, to decrease the tendency to rupture during curing. Drying is performed either artificially or by sun-heat, after which the fruits are bleached by means of superficial moistening, that of the dew preferred, followed by sunlight. Sulphurous acid is sometimes employed. The finest looking cardamoms are prepared by washing them in a

lather made from the soap-berry (*Sapindus trifoliatus* L.), and mixed with the astringent pods of an *Acacia*, alternating with washing in ordinary soapsuds, sprinkling with water at half-hour intervals through the succeeding night, and drying in the sun. It is said that whitening is also often secured, especially to conceal defects, by the use of a paste, made of rice and wheat starch, soap, and buttermilk, well rubbed in. Cardamoms are imported in chests, of the official mostly 60 to 100 pounds, of the Mangalores about double this quantity, in each chest.

Description.—From 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) long and about half as broad, oblong-ovoid, obtusely triangular in transverse section, rounded to truncate at the base, broadly and very shortly beaked, longitudinally striate, of a whitish or pale-yellowish color; 3-celled, the walls very thin, the pericarp thin, corky, and nearly tasteless, the placentæ in the axis; distended by the seeds, which are about 15 in number, each 4 Mm. ($\frac{1}{6}$ In.) long and rather more than half as broad, oblong-ovoid and irregularly angular, usually narrower at one end and grooved upon one side, reticulate-tuberculate, dark grayish-red or red-brown, furnished with a thin, hyaline aril, and representing about 70 to 75 per cent. of the total weight; odor strongly and pleasantly aromatic; taste similar, slightly pungent. Not more than 10 per cent. of ash should be yielded by the fruit, nor more than 7 per cent. by the seeds, which should be kept in the pericarps until required for use. Greenish gives as the normal ash percentage of average cardamom, about 12 per cent. in the pericarp, 6 per cent. in the seeds, 8 per cent. in the fruit. The inner albumin and embryo are filled chiefly with fixed oil and mucilage; the volatile oil is mostly contained in the large thin-walled cells of the testa.

The powder is characterized by cells packed with very minute starch-grains associated with crystals of calcium oxalate, and by the very thick-walled linear epidermal cells, with oblique ends, 10 to 20 mikrons in diameter, the last distinguishing them, according to Greenish, from those of Ceylon cardamom, in which these cells are 20 to 30 mikrons in diameter, but with thinner walls.

Ground cardamom is said to be often adulterated with ground peeled ginger, which is readily detected by its much larger starch-grains.

Constituents.—The seeds yield about 4 per cent. (*Hænsel*, 1897) of colorless or yellowish aromatic volatile oil, with a strongly penetrating but agreeable odor, and a burning, camphoraceous, somewhat bitterish taste. They contain also 10 per cent. of fixed oil, starch, gum, coloring-matter, and manganese compounds. The capsules yield 0.2 per cent. of volatile oil.

Pharmaceutical Preparations.—Aromatic Powder, U. S. P.; Compound Spirit of Cardamom, N. F.; Compound Tincture of Cardamom, U. S. P.; Tincture of Cardamom, U. S. P.

Action and Uses.—Cardamom is an aromatic, stomachic, and carminative. It relieves indigestion, and is employed to some extent as a condiment. It is rarely employed alone in medicine, but usually as an ingredient in the compound tinctures. It may be employed in dyspeptic disorders in the dose of 5 to 15 grains (0.30–1 Gm.); or an infusion, 1 ounce (30 Gm.) to $\frac{1}{2}$ pint (240 Cc.), may be given in doses of a wineglassful. (See also Tinctura Cardamomi Composita.)

Substitutes.—Wild Ceylon Cardamoms, referred to the var. *major* Smith, of the official species, but very likely distinct, are several times larger than the official, lanceolate, with a long, tapering, empty beak, and with a thick, brown, wrinkled pericarp. The most important substitutes for cardamom are the fruits of various species of the genus *Amomum* L., most of them sold as varieties of cardamom. Probably the most valuable of them is the Korarima cardamom (also called *Large cardamom*, *Guraji*, *Heel* or *Heil*, *Habhal-habashi*). It comes from Eastern Africa, but from an unknown plant. The fruits are large and usually perforated for drying on strings. The seeds have a flavor quite similar to that of true cardamom. Madagascar cardamom has a similar flavor, and is the product of *A. angustifolium* Sonn. India produces several similar substitutes. The Bengal cardamom (*Winged cardamom*, *Morung-* or *Buro-elachi*) is nearly an inch long, ovoid, and bears 9 ridges or wings toward the tip. Its seeds are quite distinct from ordinary cardamom, though pleasantly fragrant, the odor somewhat resembling that of camphor. They are yielded by *A. subulatum* Roxb. Nepaul cardamom is very similar, and may be only a variety. *Round* or *Cluster cardamom* also has a somewhat camphoraceous odor, but is more like the genuine than is the Bengal. It is the product of *A. Cardamomum* L. The fruits, as indicated, occur in clusters. They are hairy, nearly spherical, and about half an inch in diameter. The *Bastard* or *Wild cardamom* of Siam has a sharply tuberculate or subspiny fruit, and is yielded by *A. xanthioides* Wall. The *Chinese round cardamom* is from *A. globosum* Lour.

Grains of Paradise or Guinea Grains, also known as *Melegueta pepper*, are the product

of *A. Melegueta* Roscoe, of western Africa. The seeds are more rounded or round-ovoid than those of cardamom, though slightly angled by pressure. They have a little beak-like projection, softer and lighter colored than the remainder of the seed, which is of a rich reddish-brown and not reticulate like cardamom seed. The testa is crustaceous and brittle. The seed averages about 2.5 Mm. ($\frac{1}{10}$ In.) in diameter. It has little odor unless crushed, and a strong, peppery-biting taste.

CARTHAMUS.—Safflower.

Flores carthami, African or Dyers' saffron, False (American, Bastard, or Thistle) saffron, Parrot seed, E.; *Saflor, Färbersaflor, Falscher Safran, Deutscher Safran,* G.; *Carthame,* Fr.; *Cartamo, Azafrancillo, Alazor,* Sp.

The dried florets of *Carthamus tinctorius* L. (Fam. *Compositæ*).

Origin.—From a stout annual of India, largely cultivated for its useful properties in the Orient, and to some extent in Europe and other countries, besides occurring as an ornamental garden-flower. The flowers are in handsome, large orange-colored heads, terminating the erect branches, having spiny involucral scales and a bristly or subchaffy involucre, the chaff spiny-tipped. The whitish, somewhat 4-sided akenes were in use by the ancients as a laxative. The florets have been most extensively used for dyeing, especially for silks, and are still considerably so used. They are also used for rouge-making. Two distinct coloring-matters, a yellow and a red, are obtained from them. In collecting, the immature akenes are removed.

FIG. 84.

Carthamus: upper portion of floret, open and closed.

Description.—Deep-orange or brownish-red; about 2 Cm. ($\frac{4}{5}$ In.) long, tubular, deeply 5-lobed, the lobes linear, sub-equal; ovary removed; stamen-tube stout, long-exserted, much surpassed by the slender style; odor characteristic, not strong; taste bitterish. It sometimes occurs pressed into cakes.

Calendula has been used to adulterate or substitute safflower, but its ligulate florets are at once recognized.

Constituents.—Besides a little volatile oil and ordinary constituents, carthamus yields 24 to 30 per cent. of a yellow coloring-matter, *safflor-yellow* ($C_{24}H_{30}O_{15}$), soluble in water, and 0.3 to 0.6 per cent. of *carthamin* or *carthamic acid* ($C_{14}H_{16}O_7$), a red coloring-matter insoluble in water, soluble in alcohol with a handsome purple color, and very soluble in alkaline liquids, though the latter soon decompose and decolorize it. *Carthamin,* when dry, is a red-brown powder with metallic luster; with French chalk it forms "rouge."

Action and Uses.—Carthamus is employed for the same purposes as saffron. It is stimulant, diaphoretic, and in large doses laxative. The drug is never employed by practitioners, but hot infusions are frequently used by the laity to promote the eruption in the various exanthematous diseases.

The infusion contains from 2 to 4 drachms (8–16 Gm.) of the drug to a pint (480 Cc.) of boiling water, and is given in doses of a wineglassful frequently repeated.

CARUM, *U. S.*—Caraway.

Carui fructus ("*Semen*"), Br.; *Fructus carvi,* P. G. *Curaway-fruit (seed),* E.; *Kümmel, Garbe,* G.; *Carvi, Cumin des prés, Carvies,* Fr.; *Alcaravea,* Sp.

The dried nearly ripe fruit of *Carum Carvi* (*Carui*) L. (Fam. *Umbelliferæ*).

Origin.—A biennial plant, indigenous in the western Himalayas and the Caucasus, and found throughout Siberia and the greater portion of Europe, but scarce in the southern part of that continent. It is extensively cultivated in Norway, Russia, Germany, Holland, England, Morocco, and also in the United States, and is more or less naturalized in all of those countries. The hollow cylindrical stem is 30 to 90 Cm. (1 to 3 Ft.) high, branched; the leaves bi- and tri-pinnate, the flowers white. The crop is threshed and cleaned like ordinary grain. The yield per acre is between 8 and 10 hundred-weight. The Holland product is generally regarded as the finest, the annual crop of this being about 4000 tons.

Description.—Of 2 carpels, usually separated, each 4 or 5 Mm. (about $\frac{1}{5}$ In.) long and a quarter as broad, curved, oblong, narrowed toward each end, dark-brown, smooth, 5-ribbed, the ribs narrow and rather sharp, yellowish or pale-brown; oil-tubes 6; seed plane upon the face, nearly equilaterally pentagonal in transverse section; odor and taste strong, character-

istic, and agreeable. It is free from starch, and the ash should not exceed 8 per cent., about one-third of it insoluble in hydrochloric acid.

Fig. 85.

Carum.

Fig. 86.

Nigella seed (× 6).

Impurities.—Through imperfect cleaning, caraway may contain various seeds of weeds, and other substances, likely to be indicated by the presence of starch in the powder, or of dirt, indicated by an excess of ash. Fruits which have been exhausted of their volatile oil are frequently added. These are easily detected in the entire drug by their shrivelled appearance, but their detection in the powder is rather difficult.

Constituents.—Besides ordinary substances, fat, resin, gum, a little tannin and sugar, caraway contains, as its active constituent, about 5 to 7 per cent. of its peculiar volatile oil (see Oleum Carui).

Action and Uses.—Caraway is diuretic, carminative, and stomachic. It has been employed to some extent in the flatulent colic of infants, but other members of the same family of plants have met with greater favor; combined with purgative drugs, it acts as a corrective and prevents griping. The seeds are occasionally baked in bread, both to impart an agreeable flavor and to aid in digestion.

The dose of the powdered drug is from 20 grains to 1 drachm (1.3–4 Gm.). An infusion, made by adding 1 pint (480 Cc.) of boiling water to 2 drachms (8 Gm.) of the drug, is occasionally given in doses of from 1 to 2 fluidounces (30–60 Cm.), but it is probable that the large draughts of hot water are as efficacious as the drug therein contained; however, the trace of volatile oil present may aid in preventing nausea.

The volatile oil is most commonly employed (see Oleum Carui).

Black Caraway, so-called (*Nutmeg flower, Small fennel flower, Black cumin, Fitch, Gith, Roman coriander, Schwarzkümmel, Faux Cumin, Nielle, Toute epices, Quatre epices*), is the seed of *Nigella sativa* L. (Fam. *Ranunculaceæ*), a small annual, native of the Mediterranean region, and widely cultivated, especially in India. It is used by bakers the same as caraway, and is also used medicinally very much in the same way. These seeds are dark-brown or blackish, about 3 Mm. (⅛ In.) long, triangulate, with one convex side, a tuberculate testa, and an oily albumen. They are pleasantly aromatic in odor and taste, and somewhat pungent. Besides gum, albumin, sugar, 35 to 40 per cent. of fixed oil, and other ordinary constituents of seeds, they contain about 1.5 per cent. of a peculiar volatile oil and nearly an equal amount of *melanthin*, a glucoside resembling helleborin and saponin. It has also been claimed that an alkaloid is present. The seeds of *N. Damascena* L. (*Ragged lady, Love-in-a-puzzle*), native of the same region, are used similarly.

CARYOPHYLLACEÆ.—The Pink Family.

Genera about 70, species upward of 1000, being mostly herbs and growing chiefly in the north temperate zone of both hemispheres. Except for their highly ornamental properties, these plants are of little utility. A few, like chickweed, have been used as salads. A number are poisonous, due apparently, at least in part, to saponin, which is commonly contained in the plants of this family (see Saponaria). A number of the latter, in widely separated regions, have been used as diuretics and anthelmintics. Of these, the following are the best known: *Dianthus Chinensis* L., *Ku-mch* or *Shih-chuh*, and other species of *Dianthus; Tunica cretica* (L.) Fisch. (*Saponario c.* L.), of Europe; *Vaccaria Vaccaria* (L.) Britton (*Saponaria V.* L.; *Vaccaria vulgaris* Host.), the *Cow-herb* or *Cow-cockle, China, Spring*, or *False cockle*, the seeds of which yield an extract which appears to contain saponin, and which are found poisonous to rabbits, with the symptoms of saponin-poisoning; *Agrostemma Githago* L. (*Lychnis G.* Lam.), the *Corn, True*, or *Winter cockle, Corn-pink* or *Campion, Old-maid's pink*, the seeds of which are also poisonous. *Tissa rubra* (L.) Britton (*Arenaria r.* L.; *Spergularia r.* Presl.; *Lepigonum r.* Fries.; *Buda r.* Duwort), the *Red-sandwort* or *Sandspurrey*, appears to be diuretic by its large alkali-content. *Herniaria glabra* (L.) contains, in addition to saponin, *methyl-umbelliferon* (*herniarin*) and a minute amount of the alkaloid *paronychine*; it is used in catarrh of the bladder.

CARYOPHYLLUS, *U. S.*—Cloves.

Caryophyllum, Br.; *Caryophylli aromatica*, *Caryophylli*, P. G.; *Gewürznelken*, *Nägelein*, G.; *Girofle*, *Gérofle*, *Clous aromatiques*, Fr.; *Clavos de especia*, Sp.; *Garofani*, It.

The dried flower-buds of *Eugenia aromatica* (L.) Kuntze (*Caryophyllus a.* L.; *E. caryophyllata* Thunb.—Fam. *Myrtaceæ*).

Official in all pharmacopœias, some of which require the presence of from 18 to 20 per cent. of volatile oil.

Origin.—This handsome evergreen tree is supposed to have been indigenous only to the 5 small islands near the island of Jilolo, to which the name of Molucca or Clove islands was formerly exclusively applied. The tree has been entirely destroyed there, but it is now cultivated in many of the islands of the Indian Ocean, in tropical Africa, Brazil, and the West Indies. It attains a height of 9 to 12 M. (30 to 40 Ft.), and is considerably branched, the branches forming an elegant pyramidal crown, and being terminated by cymes composed of 15 to 25 flowers, producing berry-like fruits.

As soon as the buds change in color from green to pink, they are either picked by hand or detached from the trees by beating the branches with long bamboos, the buds being gathered upon cloths spread beneath the trees; they are afterward dried by exposure to the sun, whereby the color changes to brown. Between 1,000,000 and 1,500,000 pounds of cloves are annually consumed in the United States, the entire crop being about 8,000,000 pounds. The finest cloves come from Penang, the greatest quantity from Zanzibar. Collection begins in August or September, and the crop begins to arrive in London during the latter part of November.

Description.—About 1.5 Cm. ($\frac{3}{5}$ In.) long; the stem-like calyx-tube about two-thirds of the entire length and one-fourth to one-third as broad as long, usually slightly narrowed at the base, flattened and obscurely 4-angled or 4-grooved, granular, not rough-wrinkled, dark-brown, like the 4 spreading, thick and rigid triangular-ovate, obtuse teeth; corolla-bud light-brown, smoothish, broader than long, consisting of 4 imbricate petals and enclosing numerous curved stamens and 1 stout style; exuding volatile oil when scratched; odor strong, pleasantly aromatic; taste pleasantly pungent and followed by slight numbness. Cloves should not float in a horizontal position on water. They are free from starch and stone-cells, and should yield not more than 7 per cent. of ash, about one-seventh of it insoluble in hydrochloric acid.

Although nothing else can be mistaken for cloves in the entire condition, their quality calls for close scrutiny. The chief imperfections are due to careless picking, the

FIG. 87.

Clove: *a*, natural size; *b*, longitudinal section, magnified.

FIG. 88.

Clove-stalk Nat.).

FIG. 89.

Anthophylli (½ Nat.).

FIG. 90.

Caryophyllus: A, bast-cell from clove; B, bast-cells from *Anthophylli*; C, starch-grains from *Anthophylli*. (After Tschirch and Oesterle.)

immature green and the too old red buds being beaten off (in Zanzibar cloves) together with the pink ones, instead of being excluded by careful hand-picking; to careless dry-

ing, which should be done quickly and without exposure to bad weather; to admixture of the peduncles or flower-twigs (*Clove-stalks, Griffe de girofle, Nelkenstiele, Nelkenholz, Festuci caryophyllorum*), and to admixture of cloves which have been exhausted of the whole or a portion of their volatile oil. Too young cloves are small, their parts imperfectly developed, and deficient in oil. Those which are too old exhibit the corolla-bud partially or wholly expanded. Clove-stalks can be readily seen. They (Fig. 88) are about 2 Mm. ($\frac{1}{12}$ In.) in thickness, of a light-brown color, and have a distinct though not strong odor and taste of cloves. They are sometimes employed for adulterating powdered cloves, and sometimes for distilling the volatile oil, of which they contain about 4 per cent. The importation of clove-stalks into this country increased from 15,128 pounds in 1877, to 184,464 pounds in 1880. Exhausted cloves are heavily wrinkled and light, floating upon water in a horizontal position, and usually lack the corolla-bud, or "head." An artificial clove, moulded from a paste, has been reported as occurring.

In the powder, which is of a dark-brown color, all these and many other substances may enter, many of them being indicated by the presence of starch. The clove fruits (*Anthophylli, Mother-cloves, Mires de girofle, Clous Matricæ, Mutternelken*) are often included. They (Fig. 92) are about 2.5 Cm. (1 In.) long, oval, crowned with the 4-lobed calyx, and have 1 or 2 seeds in each cell. In the powder they are readily detected by the presence of their peculiar starch-grains (Fig. 90), as contrasted with those of cloves. Allspice is also sometimes used to adulterate powdered cloves.

Constituents.—(For volatile constituents, see OLEUM CARYOPHYLLI.) The unimportant constituents of cloves are 13 per cent. of gum, 6 per cent. of tasteless resin, a slight amount of vanillin, and green wax. Besides these, the following occur: From 16 to 20 per cent. of volatile oil, of which from 50 to 85 per cent. is eugenol; 10 to 13 per cent. of gallotannic acid; *eugenin* ($C_{10}H_{12}O_2$), in white pearly scales of slight clove odor, obtained from the watery distillate, and *caryophyllin* ($C_{10}H_{16}O$ or $C_{20}H_{32}O_2$), a neutral body without taste or odor, and crystallizing in silky needles, soluble in ether, slowly in alcohol, readily in boiling alcohol and boiling chloroform. With fuming nitric acid, caryophyllin yields crystals of caryophyllinic acid ($C_{20}H_{32}O_6$).

Action and Uses.—Cloves may be employed internally as an aromatic stimulant and carminative, but they are most commonly given as adjuncts to other remedies. They may be given either in powder or in infusion, 4 drachms (16 Gm.) to 1 pint (480 Cc.), to allay vomiting, remove flatus, and aid digestion. The drug is quite commonly used as a condiment to promote the digestion of fatty food. Externally, as an ingredient of the spice poultice—cinnamon, nutmeg, cloves, and allspice, of each 4 drachms (16 Gm.); black pepper, 2 drachms (8 Gm.)—it is largely employed over the epigastrium to cause expulsion of gas from the stomach; over the abdomen to relieve colic; and to the nape of the neck to prevent infantile convulsions. The dose in substance is from 5 to 10 grains (0.30–0.60 Gm.). A tincture made by percolating 1 part of powdered cloves with 4 parts of 25 per cent. alcohol may be given in doses of 20 minims to 1 fluidrachm (1.30–4 Cc.).

CASCARILLA, *Br.*—Cascarilla Bark.

Cortex cascarillæ, P. G.; *Cortex eluteriæ, C. thuris.—Sweetwood bark*, E.; *Kaskerillrinde*, G.; *Cascarilla*, F. It., Sp.; *Cascarille, Ghacrille, Écorce eleutherienne*, Fr.

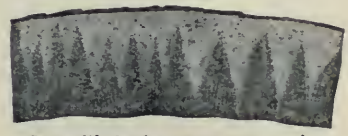
The dried bark of *Croton Eluteria* (L.) Bennett (*Clutia E.* L.—Fam. *Euphorbiaceæ*).

Cascarilla is official in nearly all pharmacopœias, some of which caution against the substitution of Copalchi bark. At least one (Ph. Belg.) has given *C. Cascarilla* (L.) Bennett (*Clutia C.* L.), of the same region, as one of the sources.

Origin.—A usually low, much-branched, fragrant flowered shrub of the Bahama Islands. It was formerly abundant in some of those islands where it is now extinct, and it is gradually becoming scarcer in the others (Eleuthera, Andros, and Long), yet the price, ordinarily about 10 dollars per hundredweight, in London, does not warrant cultivation. The annual crop is about 30,000 pounds, most of which comes first to New York. It is collected at all seasons. Besides its medicinal use, it is largely employed in scenting tobacco, flavoring liquors, and in other ways.

Description.—In quills or curved pieces of variable length and 3 to 8 Mm. ($\frac{1}{8}$ to $\frac{2}{5}$ In.) broad, the bark 1 to 3 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ In.) thick; externally silver-gray from a dense growth of lichen (*Verrucaria albissima* Ach.), or brown or gray-brown from the removal of this layer, the surface thus exposed more or less wrinkled and transversely fissured; inner surface dark red-brown, nearly smooth; fracture short and sharp, the fractured surface resinous, very dark red-brown, with thin whitish medullary rays; odor strongly aromatic, especially when burned; taste aromatic and very bitter.

FIG. 91.



Cascarilla bark: transverse section, magnified.

The powder shows an abundance of small starch-grains, mostly only 3 to 5 mikrons in diameter, elongated, prismatic crystals, and rosettes of calcium oxalate, reddish-brown resin-receptacles, and few bast-cells, about 40 mikrons in diameter and with the lumen nearly obliterated.

Constituents.—The bark yields 1 to 1.6 per cent. of greenish-yellow volatile oil (of eugenol 0.30, terpene, limonene, para-cymol, 2 sesquiterpenes, an alcohol, resin 1.1 per cent., and an oxygenated portion 10 per cent.—*H. Thoms*), 15 per cent. of resin, nauseous fatty matter, pectin, a peculiar tannin, vanillin, a basic principle, *cascarillin* ($C_{16}H_{24}O_5$, according to Naylor and Littlefield), in white odorless bitter needles or scales, very sparingly soluble in water, and sparingly in cold alcohol or chloroform. Cascarillin is not a glucoside, and is not precipitated by tannin. There is also another base allied to choline, probably *betaine*.

Pharmaceutical Preparations.—INFUSION OF CASCARILLA, Br. P.; TINCTURE OF CASCARILLA, Br. P.

Action and Uses.—Cascarilla is an aromatic stimulant and tonic, and is occasionally employed with the bitters in the treatment of gastro-intestinal disorders. It is said to be of value in atonic dyspepsia attended with flatulence, chronic diarrhœa, and dysentery. Formerly it was given as a stimulant in the low fevers and as a febrifuge in the treatment of malarial infections, but for these conditions its use has practically been abandoned. The fumes of the drug when inhaled are said to produce dizziness and intoxication.

The dose of the powdered drug is 30 grains (2 Gm.); of the infusion—1 ounce to 1 pint (30 Gm. to 480 Cc.)—a wineglassful.

Allied Barks.—MALAMBO BARK is obtained in Venezuela from *Croton Malambo* Karsten. It is in quills 12 to 25 Mm. ($\frac{1}{2}$ to 1 In.) in diameter and 15 to 20 Cm. (6 to 8 In.) long. It has a thin, soft, whitish, longitudinally fissured cork, which is easily removed, exhibiting a brown surface with fine transverse furrows; the inner surface is gray-brown, finely striate, the fracture short-splintery, the odor aromatic, and the taste unpleasantly aromatic and bitter, resembling that of cascarilla. Malambo bark does not differ materially in its action from cascarilla, and may be employed in the same dose for similar conditions as the latter remedy.

COPALCHI BARK is obtained from *Croton Pseudochina* Schlechtendal (*C. niveus* Jacquin), indigenous to Mexico. It resembles the preceding, is about 5 Mm. ($\frac{1}{5}$ In.) thick, hard and dense, has a grayish or yellowish corky layer, and beneath this is transversely fissured; the bast is reddish-brown, coarsely striate in a radial direction, and breaks with a short, irregular fracture. Copalchi bark has been given as an antiperiodic, and is said to be useful also in the treatment of diarrhœa.

Barks differing considerably from those described, and which are occasionally found in commerce as malambo and copalchi barks, are obtained from different plants. The composition of both barks is probably similar to that of cascarilla. Holmes (1874) described a bark which was probably derived from *Croton lucidus* L., and was found as an admixture in cascarilla; it had a fawn-colored, firmly adhering corky layer, was reddish and closely ridged upon the inner surface, had an astringent, slightly bitter taste, and yielded a darker-colored tincture and infusion than cascarilla.

C. PHEBALOIDES R. Br., of Australia, is there used as *Native cascarilla*, and is said to have an agreeable aromatic, bitter taste.

The bark of *C. erythœma* Mart. (*Casca de Sangue de Drago*), of Brazil, is there a favorite astringent for intestinal and urethral diseases.

CASEINUM.—Casein.

Caseinogen, E.; *Casein, Käsestoff, Milchcasein*, G.; *Caséine*, Fr.

Casein is a nucleoproteid characterized by its coagulability by acids, and particularly by rennet, and a high content of sulphur and phosphorus in organic combination. It is

acid in character, combining with alkalies and the alkali earth (lime) bases to form soluble combinations, in which latter form it constitutes the principal proteid of milk. The term *caseinogen* has been introduced to distinguish the natural soluble (as existent in milk secretions) form from the altered coagulated form, which is designated as *casein*. *Paracasein* (Hammersten) applies to the more insoluble part of the coagulum obtained by the action of rennet upon caseinogen.

Preparation.—Caseinogen may be obtained from milk by saturating centrifugated milk with sodium chloride (free from sodium sulphate, washing the precipitate thoroughly with a saturated solution of sodium chloride, dissolving the washed precipitate in a minimum of 0.1 per cent. aqueous solution of sodium hydroxide, care being taken not to leave the solution permanently alkaline, filtering, precipitating the filtrate with dilute (1.5 per cent.) acetic acid, washing the precipitate thoroughly with water, and repeating the successive treatments with alkali solution, filtering, precipitating with acetic acid, and washing with water 3 or 4 times. The final washed precipitate is pressed to express water as much as possible and then carefully dried. The caseinogen thus prepared is more readily soluble than the *casein* prepared by the following method:

Centrifugated milk is diluted with about 10 volumes of water, warmed to 35°–40° C. (95°–104° F.), and coagulated either by means of rennet * or by adding sufficient dilute acetic acid (1.5 per cent.). The coagulum is first washed carefully with water by decantation, and then thoroughly on a filter. It is then dissolved in a minimum of an aqueous dilute solution (0.1 per cent.) of sodium hydroxide, care being taken not to allow the solution to remain alkaline. The solution is filtered to remove fat and the filtrate precipitated with dilute acetic acid, the resulting precipitate carefully washed with water, redissolved in dilute alkali solution, and the successive operations of precipitation, etc., repeated 3 or 4 times. The final precipitate is compressed to remove water and then triturated with alcohol and washed with the same to remove moisture, and finally thoroughly exhausted with ether to remove the remaining traces of fat. The product is first dried at ordinary temperatures, and then transferred to a drying oven and the drying completed at a temperature not exceeding 100° C. (212° F.), and finally ground to a fine powder.

Properties.—Pure casein, according to the concentration from which it is precipitated, presents in the moist coagulated form white flakes (from dilute solution) or white stringy masses (from concentrated solution), which on drying form colorless to yellowish transparent horn-like masses, and these on being powdered produce a white or yellowish-white, odorless, tasteless powder, which is insoluble in water, alcohol, ether, or concentrated solutions of sodium chloride or magnesium sulphate. Casein is acid in reaction if placed on moist blue litmus-paper, although the aqueous extract is neutral to the same. It is soluble in aqueous solutions of alkali hydroxides or carbonates, forming caseinates, which from concentrated solutions may be precipitated by acetone (see Nutrose). It is soluble in 1 per cent. aqueous solutions of sodium fluoride, ammonium and potassium oxalate (Arthus). It forms a white opalescent solution with an aqueous solution of calcium hydroxide, and liberates CO_2 from calcium carbonate. It is soluble in dilute (0.1 per cent.) hydrochloric acid. The aqueous solutions of casein are strongly lævo-rotatory, the neutral solution showing a specific rotatory power $[\alpha]_d = -80°$ Hoppe-Seyler; dilute alkaline solutions —76°; strongly alkaline solutions —91°; dilute hydrochloric acid solutions —87°.

When casein or a neutral solution of the same is added to concentrated hydrochloric acid, *acid casein* is formed, which is soluble in water. It is acted upon by nascent chlorine, forming *chlorocasein* compounds, containing according to degree of saturation 8.32 per cent. (Panzer, *Zeit. f. Phys. Chem.*, 1901, *33*, pp. 131–150) to 14 per cent. of chlorine (Habermann and Ehrenfeld, *loc. cit.*, *32*, pp. 468–475). When casein is hydrolized with hydrochloric acid leucine, tyrosine, glutamic acid, and amino-acids result. It forms insoluble combinations with formaldehyde. Casein is distinguished from alkali-albuminates, to which it is closely related, by its neutral solutions not being coagulated by heat; by being precipitated by acetic acid; more particularly by being coagulated by the active principles of rennet *chymosin* and *rennin;* by coagulation by certain specific bacteria without the production of acid; and by its high percentage content of sulphur and phosphorus in organic combination. Its percentage composition is given by Hammersten as C 53, H 7, N 15.7, S 0.8, P 0.85, O 22.85 per cent. Lime salts are essential to the coagu-

* Note that the coagulation by rennet alters the casein more than its precipitation by acetic acid.

lation of casein by rennet, for purified casein may be acted upon by rennet at 40° C. (104° F.), the most favorable temperature for the action of rennet, without causing coagulation, but the coagulation takes place immediately upon the addition of a soluble lime salt. Neutral solutions of casein are completely precipitated by salt or magnesium sulphate apparently without alteration, but solutions of lead, mercuric nitrate, and particularly solutions of copper completely precipitate the casein by transposition as caseinates of the respective metals. Solution of corrosive sublimate does not precipitate neutral solutions of casein, but on the addition of alcohol mercury compounds of casein are precipitated, which are soluble in slightly alkaline aqueous solutions, but in which neither hydrogen sulphide nor ammonium sulphide gives a reaction for mercury. By suspending casein in strong alcohol and boiling it with a solution of salts of silver, mercury, or iron, various compounds are produced of the respective metals, more or less insoluble in water, but soluble in dilute alkaline solutions, and in none of which ammonium sulphide indicates the presence of the metal. Casein also forms combinations with iodine.

Tests.—Pure casein should meet the following requirements: a white or only faint yellowish, dry, non-hygroscopic, odorless, tasteless powder or mass; the 10 per cent. aqueous extract should be neutral (freedom from acid) and leave no residue on evaporation (albumin, milk-sugar); nor should the alcohol or ether extracts leave a residue (fat); the ash should not exceed 1 per cent.

Casein for technical purposes is prepared by precipitating centrifugated milk with dilute sulphuric, or better with acetic acid, and thoroughly washing the coagulum with water by kneading to free it from acid, milk-sugar, and albumin. The mass is then dried and finally ground to a fine powder. It is a light-yellowish colored powder, usually showing a high content of ash, and considerably less soluble than the pure casein. It is rendered soluble in the arts by treatment with sodium bicarbonate, borax, or ammonia, being used as a sizing for paper, the preparation of glues and cements, leather polishes, waterproof paints, the preparation of coloring-matters, and fixation of dyes in calico-printing.

Action and Uses.—Casein is employed in pharmacy in the manufacture of emulsions.

Pharmaceutical Preparations.—Unna has suggested the following compounds as desirable vehicles for dermic medication:

Unguentum Caseini. *Casein ointment*, E.; *Caseinsalbe*, G.—This is prepared by dissolving 14 parts of dried and powdered casein in 50 parts of a weak alkaline solution, containing 0.345 part of potassium hydroxide and 0.085 part of sodium hydroxide. To the solution are added 7 parts of glycerin and 0.5 part of carbolic acid, and finally 21 parts of vaselin. When the latter has been incorporated, sufficient water is added to bring the weight of the finished product up to 100 parts. Casein ointment has the consistence of very thick cream and loses water on exposure. It is incompatible with acids and acid salts, but is miscible with mercury, tar, balsam of Peru, zinc oxide, resorcin, pyrogallol, and ichthyol. As the latter substance has a tendency to stiffen the ointment, it should be mixed with a little water before incorporation.

Vernix Caseini. *Casein varnish*, E.; *Caseinfirniss*, G.—Two varieties of this preparation are in use, known respectively as borated and glycerinated casein varnish. Borated casein varnish is made by dissolving 25 parts of dried casein and 3 parts of borax in 125 parts of water with the aid of a moderate heat. Glycerinated casein varnish is prepared by dissolving 5 parts of dried casein in 15 parts of 28 per cent. ammonia water, adding 5 parts of glycerin, and finally driving off the excess of ammonia by heat. The residual mass is readily miscible with twice its weight of boiling water, yielding a fine creamy mixture, which permits of the incorporation of powdered substances without likelihood of separation.

COMPOUNDS OF CASEIN.

Ammonii Caseinas. *Eucasinum. Ammonium caseinate, Ammonium-casein, Eucasin*, E.; *Casein-ammonium, Casein-ammoniak, Eucasin*, G.—This preparation, which has been introduced into medicine under the name *eucasin*, is obtained by passing ammonia gas over finely powdered dry casein until the casein forms a nearly clear solution with water. Heat is developed during the absorption of ammonia. Eucasin occurs as a white or faintly yellowish-white powder, having scarcely any odor and taste. It forms a milky or opalescent solution with warm water.

Sodii Caseinas. *Sodium caseinate, Nutrose*, E.; *Casein-natrium, Nutrose*, G.—A food preparation patented in Germany and prepared from centrifugated or skimmed milk by precipitating the casein, washing it with water, and then adding just sufficient sodium hydroxide

solution to dissolve the moist casein. The solution is either evaporated in vacuo and the dry residue powdered and washed with alcohol to free it from alkali, or precipitated with acetone, and the precipitated casein washed with alcohol and finally with ether, and then dried. Nutrose occurs as a white amorphous powder, almost odorless and tasteless, insoluble in alcohol and ether, difficultly soluble in cold water, readily soluble in hot water, neutral in reaction to litmus but acid to phenolphtalein, and contains, according to Aufrecht: albuminoids, 65.2 per cent.; water, 10.5 per cent.; ash, 4.15 per cent.; nitrogen-free substances, 20.15 per cent. It is considered a valuable food-product.

CASSIA FISTULA, *U. S.*—Purging Cassia.

Cassiæ Pulpa, Br.; *Fructus Cassiæ fistulæ.—Pudding-stick (or Pipe)*, E.; *Purgiercassie, Fistelkassie, Rohrenkassie*, G.; *Casse officinale, Casse en batons*, Fr.; *Cassia*, It.; *Caña fistula*, Sp.

The dried ripe fruit of *Cassia Fistula* L. (*Cathartocarpus F.* Pers.—Fam. *Leguminosæ*).

Cassia Fistula is official in many pharmacopœias, some of which direct that it be rejected when the seeds can be heard to rattle on its being shaken. In the Br. P. the pulp alone is official.

Origin.—A tree 9 to 15 M. (30 to 50 Ft.) high, with large pinnate leaves appearing simultaneously with the long pendulous racemes of fragrant, golden-yellow, dark-veined flowers. Indigenous in the East Indies, it is now met with, spontaneously and under cultivation, in Egypt and other parts of Africa, in the West Indies, and Brazil.

Fig. 92.

Cassia fistula: part of pod (Nat.).

Description.—Cylindrical, 40 to 60 Cm. (16 to 24 In.) long, nearly 25 Mm. (1 In.) in diameter, blackish-brown, somewhat veined, the sutures smooth, forming 2 longitudinal bands; indehiscent, the cavity divided transversely into numerous cells, each containing a reddish-brown, glossy, flattish-ovate seed imbedded in a blackish-brown sweet pulp; odor resembling that of prunes.

Constituents.—Treated with water, the fruit yields about 30 per cent. of pulp, 60 per cent. of which is sugar, with mucilage, pectin, tannin, etc. It acts best if kept in the pod until required for use.

Pharmaceutical Preparation.—Confection of Senna, U. S. P.

Action and Uses.—As a laxative, Cassia Fistula may be employed with success in the treatment of habitual constipation. In doses sufficiently large to purge, it produces severe gripiug, and for this reason is rarely given alone. It is considered by some a useful drug when combined with other laxatives. The confection of senna, which contains cassia, is the usual form in which it is administered.

The dose of cassia as a laxative is from 1 to 2 drachms (4–8 Gm.). As a purge, it may be given in the dose of 1 ounce (30 Gm.).

Allied Products are obtained from *C. bacillaris* (L.) Pers. (*Cassia b.* L.) and *C. moschata* Don (*Cassia m.* Kunth), of tropical America, the fruits being very similar. *C. Brasiliana* (Lam.) Pers. (*Cassia B.* Lam.; *C. grandis* L. b.; *C. mollis* Vahl.) yields a large purging cassia, sometimes known as *Horse cassia*, which is 60 Cm. (2 Ft.) or more long, often curved, strongly laterally compressed, 38 Mm. (1½ In.) broad, rather coarsely veined, and has the dorsal suture indicated by 1 convex band and the ventral suture by 2 prominent obtuse ridges.

CASTANEA.—American Chestnut.

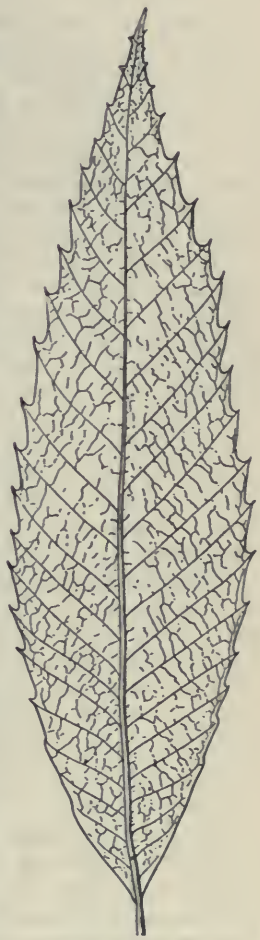
Folia Castaneæ.—Kastanienblätter, G.; *Feuilles de chataignier, F. de marronier*, Fr.; *Castaño*, Sp.

The dried leaves of *Castanea dentata* (Marshall) Borckh. (*C. vesca* Gærtn.—Fam. *Fagaceæ*), collected in September or October, while yet green.

Origin.—A well-known large forest-tree of the eastern United States, greatly valued for its light and durable timber and for its fruit.

Description.—15 to 25 Cm. (6 to 10 In.) long, including the short, stout petiole, and 5 to 8 Cm. (2 to 3 In.) broad; oblong, the base somewhat tapering, the apex attenuate; coarsely spinulose-serrate with rounded sinuses, regularly feather-veined, thickish, nearly smooth, dark-green above, pale-green and slightly yellowish underneath; almost inodorous; taste somewhat astringent.

Fig. 93.



Chestnut leaf (½ Nat.).

If collected earlier in the season, chestnut leaves are deficient in tannin. Such leaves can be distinguished by their lesser thickness and their more satiny appearance.

Constituents.—The most important constituent is about 9 per cent. of yellow tannic acid. Lloyd claims that the mucilaginous constituent, soluble in hot water, and insoluble in alcohol, is active. There are also a little fat, resin, and 5 to 6 per cent. of ash.

Action and Uses.—The effect of chestnut leaves upon the system has not been determined, but judging from their action in the treatment of whooping-cough castanea may be inferred to be a respiratory sedative. It may be given in the form of the fluidextract in doses of from ½ to 1 fluidrachm (2–4 Cc.) several times daily, or an infusion (1 ounce to a pint—30 Gm. to 480 Cc.) may be taken ad libitum.

Other and Related Products.—The leaves of the other species of the genus, *C. Castanea* (L.) Lyons (*Fagus C.* L., *C. sativa* Mill.), the *European* or *Spanish chestnut*, and *C. pumila* (L.) Miller, and other *Chinquapins* or *Small chestnuts* of our Southern States, are doubtless identical in composition and properties. The barks of all are strongly astringent, and a tanning extract made from that of the European species is an important commercial product. The nuts of all are edible and highly esteemed. Those of the chinquapin are most, and those of the European least, sweet. Chestnuts of the species here considered contain 30 to 40 per cent. of starch, 3 to 4 per cent. of proteids, about 2 per cent. of fat, 0.5 to 2 per cent. of sugar, gum, organic acids, and a bitter principle. They are a delicious luxury, and fairly digestible when thoroughly cooked, either by roasting or boiling. The *Maronnier* is one of our most delicious and expensive confections, made by a very long and tedious process of preserving the large European chestnut. Of that species, many cultivated varieties are grown for their nuts, which constitute a most important food-product in Italy, where the annual crop is estimated at 360,000 tons. They are ground into flour, which in some localities almost takes the place of other sorts. Great quantities are also made into confections, a single manufactory in Lyons being said to consume 25,000,000 pounds annually for this purpose.

CASTOREUM.—Castor.

Bibergeil, G.; *Castoreum*, Fr.; *Castoreo*, It., Sp.

The dried preputial follicles, and their secretion, obtained from the beaver, *Castor Fiber* L. (*Castor Americanus* Cuvier—class *Mammalia*, order *Rodentia*), and separated from the somewhat shorter and smaller oil-sacs which are frequently attached to them.

Origin.—This well-known animal inhabits the northern hemisphere between latitude 33° and 68°, but is fast disappearing from the southern portions of this region. The old world form is believed by many to constitute a distinct species, being larger and lighter-colored and its habits differing markedly.

Anus, genitals, and follicles communicate in both sexes with one canal or cavity located near the tail. In the male, a pair of oil-sacs, containing the formerly official *Axungia castoris*, terminates in the cloaca; the castor-sacs, located near the former, open by a common aperture in the preputial canal. The female has the castor-sacs below the os pubis on each side of the vagina. The wall of the castor-sacs consists of 4 distinct coats; the outer one is cellular, resembles hog's bladder in texture, and encloses a fibrous layer, which is followed by a vascular, and this by an iridescent glandular coat, with many folds and numerous semilunar scales upon the inner surface, the whole being

covered by a thin epithelium. J. Fuchs (1881) states that the castor is altogether separated from glands contained in the inner coat of the sac.

When fresh, castor-sacs are flesh-colored and soft, but become harder and brown in color by drying, which is performed carefully over a fire. The contents, when fresh, are yellowish, unctuous, and odorous, but by drying become brown and friable, not fusible.

Castor is commercially distinguished by the countries from which it is obtained, the most highly valued being obtained from Russia and Siberia.

Castoreum Sibiricum (Castoreum Moscoviticum, Rossicum, Germanicum, or Europæum).—These sacs are oval or globular-pyriform, united at the narrowed end in pairs, the contents of a dull, rather light-brown color, and a strong peculiar odor. The sacs vary in weight from about 3 to 8, or occasionally even 14 ounces, and if not too dry the 2 outer coats may be readily separated. This kind is mostly collected in Siberia and Eastern Russia, the sacs from Western Russia and Germany being usually smaller. It is now rarely met with in commerce.

Castoreum Canadense (Castoreum Americanum, or Anglicum).—This is the variety generally met with in commerce. The sacs are more elongated, flatter, and usually more wrinkled and folded, than those of the preceding; they vary from club-shaped to narrow pyriform, are united in pairs, mostly between 1 and 4 ounces (rarely 8 ounces) each in weight; the outer coats adhere pretty firmly; the contents are often slightly glossy; the odor is aromatic, but weaker than the preceding; the taste about the same, pungent, bitter, and rather nauseous.

Russian castor yields 60 to 68 per cent. of its weight to alcohol; American, between 40 and 45 per cent. The tincture of the former yields with much water a milky mixture, which becomes nearly clear on the addition of ammonia. The mixture obtained from the tincture of the latter is brownish, the precipitate being only partly soluble in ammonia.

Constituents.—Castoreum consists of 1 to 2 per cent. of volatile oil, with a strong odor of the drug, a dark-brown, bitter, acrid resin, osmazone, salicin (Wöhler), urates, benzoates, etc. *Castorin*, a neutral principle in long white prismatic crystals, of castor odor and little taste, and soluble in ether, benzin, and oil of turpentine, constitutes 2 per cent. of Canadian castor and 4.6 per cent. of the Russian. The inorganic constituents are phosphates and sulphates of calcium, magnesium, potassium, and ammonium. The ash should not be above 5 per cent. Some specimens (chalky castor) contain much calcium carbonate, and are said to come from diseased animals.

Pharmaceutical Preparation.—Ethereal Tincture of Castor, N. F.

Action and Uses.—Because of its variable quality, castor is at present rarely employed in medicine. In moderate doses it stimulates the nervous system. In larger amounts it increases the rapidity of the pulse and causes nervous excitement. Castor has been used in the treatment of amenorrhœa and uterine colic, and may be tried in hysteria, epilepsy, and other convulsive seizures. The drug is probably most efficacious in the treatment of the low fevers, especially where nervous manifestations are prominent.

The dose of castor varies from 10 to 60 grains (0.60–4 Gm.). Tincture of castor, made by macerating 1 ounce (30 Gm.) of bruised castor in 1 pint (480 Cc.) of alcohol, may be given in doses of from 1 to 4 fluidrachms (4–16 Cc.).

CATAPLASMA KAOLINI, *U. S.*—Cataplasm of Kaolin.

Cataplasme de terre à porcelaine, Fr.; *Porzellanthonumschlag*, G.

Preparation.—Kaolin, in No. 80 powder, 577 Gm.; boric acid, in fine powder, 45 Gm.; thymol, 0.5 Gm.; methyl salicylate, 2 Gm.; oil of peppermint, 0.5 Gm.; glycerin, 375 Gm.; to make 1000 Gm. Heat the kaolin in a suitable vessel at 100° C. (212° F.) for 1 hour; mix it intimately with the boric acid, and then incorporate the mixture thoroughly with the glycerin; finally, add the thymol, which has been dissolved in the methyl salicylate and the oil of peppermint, and make a homogeneous mass. It should be kept in an air-tight container.

If apothecaries' weight is more convenient, the following quantities may be used,

the finished product weighing somewhat over 1 pound: Heat 4432 grains of kaolin at 100° C. for 1 hour; mix it intimately with the boric acid, and then incorporate the mixture thoroughly with 2880 grains of glycerin; finally, add 4 grains of thymol, which have been previously dissolved in a mixture of 4 grains of oil of peppermint and 16 grains of methyl salicylate.

Cataplasm of kaolin is a smooth dark-gray paste, rather soft when freshly made, but gradually becoming firmer. It resembles soft putty in appearance and has a pleasant odor due to the mixture of thymol, methyl salicylate, and peppermint. It is essential that the kaolin be passed through a No. 80 sieve, as directed, in order to obtain a satisfactory product.

Action and Uses.—This preparation depends for its virtue principally upon the hygroscopic power of the glycerin contained. The boric acid, thymol, and methyl salicylate render it mildly antiseptic. It acts as a mild counterirritant and exosmotic, and is designed to replace the flax-seed and mustard poultices, liniments, stupes, and other counterirritants.

By inducing superficial hyperæmia, it relieves congestion and pain of inflammations situated deeply beneath the area of application, as in pneumonia, pleurisy, bronchitis, peritonitis, etc. Its beneficial effect is exhibited also in superficial inflammations, as sprains, boils, periostitis, synovitis, mastitis, orchitis, etc., in which it tends to bring about depletion of the congested vessels and absorption of the inflammatory exudate, and to lessen pain.

The cataplasm should be applied freely and as hot as can be borne. It is brought to the desired temperature by immersing the container in hot water.

After being spread freely upon the skin surface it should be covered with cotton and a bandage.

Its hygroscopic property is impaired if it be exposed for a long time to the air or be brought in contact with water, hence the container should be kept tightly closed.

CATAPLASMATA.—Cataplasms.

Poultices, E.; *Cataplasmes*, Fr.; *Umschläge, Breiumschläge*, G.

Poultices are soft pasty or mushy preparations composed of coarse or fine powders, capable of absorbing large quantities of fluids, either water or watery or oily solutions. They are intended as emollient, discutient, stimulating, or relaxing applications, and are made by forming a soft paste of the substance, usually meal or flour, with the hot liquid and spreading this thickly on cloth. While the ingredients for poultices are generally furnished by the pharmacist, their preparation is left to the nurse, since their action usually depends upon the moist heat they are capable of imparting to the skin, and they must be applied immediately after they have been made. In order to prevent loss of heat and evaporation of moisture, it is customary to cover poultices with thick cloths and oiled silk or sheet rubber.

The solid ingredients of poultices being chiefly useful for holding large quantities of fluid, a convenient substitute has been introduced, known as spongiopiline, both for absorbing excessive moisture and applying water or medicated solutions to the affected parts. Spongiopiline consists of a thick cloth containing small pieces of sponge on one side and covered with some waterproof substance, rubber or varnish, on the other.

Cataplasms have been discarded in nearly all modern pharmacopœias, notably those of the United States, Great Britain, and Germany. The formulas appended have been collected from different sources:

UNOFFICIAL CATAPLASMS.

Cataplasma Aluminis. *Alum Poultice.* A cooling and astringent preparation made by coagulating the albumin or white of 2 eggs by addition of 60 grains of powdered alum. The effects and properties of the alum poultice are fully described under *Alumen.*

Cataplasma Carbonis. *Charcoal Poultice.*—This is prepared by macerating 2 ounces of bread crumbs for 10 minutes in 10 fluidounces of boiling water, gradually adding 1½ ounces of linseed meal and afterward ¼ ounce of finely powdered wood charcoal. Before application another ¼ ounce of wood charcoal is sprinkled over the surface of the poultice.—Br. P. 1885. Charcoal poultice is applied to gangrenous and fetid ulcers as a deodorant and emollient. It should be frequently changed.

Cataplasma Dauci, vel Carotæ. *Carrot Poultice.*—Prepared by mixing 4 ounces of garden carrot, scraped, 1 ounce of corn meal, and sufficient boiling water to make a soft poultice.

Cataplasma Fermenti. *Yeast Poultice.*—The Br. P. (1885) directed that 6 fluidounces of beer yeast be mixed with an equal volume of water heated to 38° C. (100.4° F.) and 14 ounces of wheaten flour then added. The mass is placed near the fire till it rises, which occurs speedily.

Another formula calls for a mixture of ½ pint of tepid milk, 2 fluidounces of yeast, and sufficient powdered elm bark to make a soft poultice. Yeast poultice is sufficiently active to induce considerable pain at times. It hastens the removal of sloughing tissues and overcomes and prevents the fetor of gangrenous and cancerous ulcers. It is also occasionally applied as a gentle stimulant to chronic ulcers.

Cataplasma Lini. *Linseed or Flaxseed Poultice.*—This very popular poultice is made by adding 4 ounces of linseed meal gradually and with constant stirring to 10 fluidounces of boiling water. If ½ ounce of lard be added to the soft paste, it will retain its soft consistence for a longer time. Flaxseed poultice is employed to hasten the suppuration of boils, felons, etc.; its application, however, is quite painful and it may be the cause of a double infection. It is also employed to relieve inflammation in its earlier stages, but the hot antiseptic fomentation is much superior. This poultice causes the skin to become white and wrinkled, and occasionally induces a vesicular or pustular eruption. This may be prevented, however, by coating the skin with lard or olive oil prior to its application.

Cataplasma Lobeliæ. *Lobelia Poultice.*—The American Dispensatory (1898) recommends a mixture of equal parts by weight of powdered lobelia and ground elm bark to be added to sufficient warm weak lye to form a poultice. The employment of the lobelia poultice is discussed under *Lobelia.*

Cataplasma Sinapis. *Mustard Poultice.*—This is readily made by mixing ground mustard seed with sufficient warm (tepid) water to form a moderately soft paste. If a weaker poultice be desired, the mustard may be diluted with an equal quantity of corn meal or flour. Vinegar should never be added to mustard poultice. Mustard poultices, at one time a favorite remedy, have been almost wholly superseded by ready-made mustard plasters (see CHARTA SINAPIS), a more convenient and cleanly mode of application. Only warm, not hot, water should be used for making mustard poultices, as their virtue lies in the volatile oil generated by the interaction of the constituents of mustard in the presence of water, and which latter are injured by very hot water. The mustard poultice not only acts as a rubefacient, but, if applied sufficiently long, also as a vesicant. It may also be sufficiently active to produce sloughing. Its application produces almost from the first a sense of burning which continues for some time after its removal. In persons with delicate skin it should be diluted with equal parts of flour, or linseed meal, and for children the poultice should contain 1 part of mustard to 3 parts of flour or linseed meal. Care should be taken that a mustard poultice is not applied to exposed portions of the body, as it frequently leaves a permanent brown stain upon the skin. If the burning of the mustard becomes excessive it may be relieved by applying lint which has previously been soaked in a mixture of equal parts of lime water and olive oil. This poultice is employed for the purpose of relieving flatulent colic, acute inflammation of the abdominal or thoracic viscera, neuralgia, and muscular rheumatism. It has also been applied at the nape of the neck for the relief of headache and cerebral congestion.

Cataplasma Sodæ Chlorinatæ. *Chlorinated Soda Poultice. Chlorine Poultice.*—The Br. P. (1885) directed that 4 ounces of linseed meal be mixed with 8 fluidounces of boiling water and afterward 2 fluidounces of solution of chlorinated soda (Labarraque's solution) be added. This poultice may be employed as a stimulant and deodorant to offensive and sloughing ulcers.

Cataplasma Stramonii. *Stramonium Poultice.*—This preparation, in favor among eclectic physicians, may be made by bruising fresh stramonium leaves and adding a small quantity of hot water to form a moist poultice. Stramonium poultice affords a sedative application which may be employed in superficial neuralgias and myalgias. For further uses of the drug, see *Stramonium.*

Cataplasma Syrupi Fusci. *Molasses Poultice.*—This popular application for burns and scalds is prepared by adding enough wheaten flour to New Orleans molasses to form a soft easily spreading mass.

CATARIA.—Catnep.

Herba Nepetæ (or Catariæ); *Catmint, Catrup*, E.; *Katzenminze, Katzenkraut*, G.; *Cataire, Chataire, Herbe aux chats, Menthe de chats*, Fr.

The dried leaves and flowering tops of *Nepeta Cataria.* L. (*Cataria vulgaris* Moench.—Fam. *Labiatæ*).

Origin.—A tall, widely pyramidal-branching perennial herb of Asia and Europe, extensively naturalized in the United States, where it grows near dwellings, in waste places, and along roadsides. It is named from the peculiar fondness of cats, shared by other feline animals, for it.

FIG. 94.

Cataria: leaf, under surface (× ¾); flower (× 2).

Description.—Softly gray-hairy throughout, the branches quadrangular; leaves opposite, exstipulate, petioled, the blades 2.5 to 7.5 Cm. (1 to 3 In.) long and nearly as broad, triangular-ovate, rounded or subcordate at the base, acute, crenate-serrate, thin, grayish-green, hairy above and downy underneath; flowers panicled, pedicelled or subsessile; calyx tubular, 15-nerved, obliquely 5-toothed; corolla whitish with purple spots, the tube slender below, dilated upward, the limb strongly 2-lipped, the upper lip 2-lobed, the lower 3-lobed, with the lobes crenate, the middle one much larger; stamens 4, perfect, the lower pair longer, the anthers divergent; fruit of 4 ovoid, obtuse, compressed, smooth nutlets; odor peculiarly aromatic; taste aromatic and pungent, slightly bitter.

Constituents.—The plant contains a small quantity of oxygenated volatile oil, fixed oil, wax, gum, some tannin, sugar, and a bitter principle of acid reaction. It yields about 12 per cent. of ash.

Action and Uses.—Catnep is employed in infusion, made with 1 ounce (30 Gm.) of the whole plant in 1 pint (480 Cc.) of boiling water, in domestic practice as an emmenagogue and antispasmodic. It has been recommended as a carminative in the flatulent colic of infants, and is supposed to be a useful remedy in hysteria. The plant is largely eaten by cats. It is thought by some to excite sexual activity. The dose of the infusion is from 1 to 4 fluidrachms (4–16 Cc.).

CATECHU, *P. G.*—Catechu.

Catechu nigrum; Black catechu, Cutch, E.; *Ketechu, Pegu-Catechu*, G.; *Cashoultie* (*Cachou de Pégu*, Cod.) Fr.; *Succus Catechu, Bombay-Catechu*, Russ.; *Cato, Tanoma Cato*, Port.; *Terra Catu, Pegy*, It.; *Catecu*, Sp.

An extract prepared from the heart-wood of *Acacia Catechu* (L. f.) Willd. (*Mimosa C.* L. f.—Fam. *Leguminosæ*).

Catechu is official in nearly all pharmacopœias, though not all agree in specifying this substance. Some admit also the product of *A. Suma* Kurz, of southern India. The Port. Ph. makes Gambir Catechu known as *Pale catechu* or *Terra japonica* (see GAMBIR), an allowable substitute, while the U. S. and Br. P. specify this only, but retain the name Catechu. In reply to criticisms, Dr. Attfield declares it the intention of the Br. P. to destroy the official distinction between the two, in spite of their different origin, because of their chemical identity.

Origin.—A rather small tree, distributed widely and abundantly in dry localities through the East Indies, and presenting several varieties, or species as regarded by some authors. It has become naturalized to some extent in the West Indies, but the commercial product is wholly from the Orient.

When about a foot in diameter, the trunk is regarded as mature, although smaller ones are much used. After passing 25 or 30 years of age, they are considered much better. The trunks are preferred in proportion as they show a larger number of white spots in cross-section. These spots consist of the large pores filled with a white substance, which is more or less impure catechin. Their proportion ranges from 1 per 1000 to 1 in 3. In cavities of the wood are found masses of almost pure catechin, eagerly sought by the collectors and used under the name *khirsal*, like the *kath* to be presently described, for chewing with betel. The bark and sap-wood being carefully removed, the remainder, of a deep-red or nearly red-black color, is cut into chips and boiled in water for about 12 hours, or until the water is reduced to a half. Over-boiling injures the product, changing part of the catechin to catechutannic acid. The chips are removed and the liquid

evaporated to a syrupy consistency. It is meantime vigorously stirred or beaten, this being deemed essential to its quality. It is then allowed to cool until it can be handled, when it is spread on leaves or ashes of cow-dung, in moulds, chiefly of clay, and left until morning, when it is hard and dry, and is broken or cut into suitable pieces for marketing. In different localities and by different makers, various minor modifications of this general method are introduced. A very fine product, rich in catechin, made by the vacuum process, from trunks imported to Glasgow, was rejected by dealers on its appearance, which differed markedly from that of the native product. The yield of catechu varies from 3 to 10 per cent. of the weight of a good wood.

Description.—In irregular masses, containing fragments of leaves, dark-brown or blackish, brittle, somewhat porous and glossy when freshly broken. It is nearly inodorous, and has a strongly astringent and sweetish taste.

If a portion of catechu be digested with 10 times its weight of alcohol, and the liquid filtered, the undissolved matter, after being dried at 100° C. (212° F.), should not exceed 15 per cent. of the original weight.

The tincture, diluted with 100 parts of water, acquires a green color on the addition of ferric chloride test-solution.

If 2 parts of catechu be boiled with 20 parts of water, a brownish-red, turbid liquid will be obtained which turns blue litmus-paper red.

Upon incineration, catechu should not leave more than 6 per cent. of ash.

Constituents.—*Catechutannic acid* (catechu-red or mimotannic acid, $C_{36}H_{34}O_{15}$), the chief constituent, is a dark-red, amorphous powder, soluble in water, alcohol, and ether, and is, unlike most tannins, not a glucoside. It does not yield pyrogallic acid when heated. It yields a greenish-gray precipitate with ferric chloride. It constitutes 20 to 25 per cent. of catechu, which also contains 13 to 34 per cent. of catechin (catechuin or catechuic acid), gum, extractive, and quercetin. Catechin ($C_{19}H_{18}O_8$ or $C_{21}H_{20}O_9 + 5H_2O$) crystallizes in long silky needles, is bitter, slightly acid, and soluble in about 1100 parts of cold water, 3 parts of boiling water, 6 of cold alcohol, 3 of boiling alcohol, and in ether, glacial acetic acid, turpentine, and alkaline solutions. It does not precipitate alkaloids or gelatin, but is rendered available for tanning, etc., by the action of heat or acid, which changes it into catechutannic acid, and another tannin ($C_{38}H_{32}O_{14}$). Continued boiling with dilute sulphuric acid produces *catechuretin* ($C_{38}H_{28}O_{12}$) and an anhydride ($C_{38}H_{30}O_{13}$). By dry distillation, it yields pyrocatechin, and fused with potassa it yields phloroglucin and protocatechuic acid.

Protocatechuic acid, $C_7H_6O_4$, is formed from certain tannins, numerous resins, gum resins, and other substances by adding them to melted potassa. It crystallizes in colorless shining needles or scales containing a molecule of water, dissolves readily in ether, alcohol, and hot water, melts at 199° C. (390.2° F.), and at a higher heat is decomposed into carbon dioxide and pyrocatechin. Its solution is colored dark-green by ferric chloride, the color changing to blue, and subsequently to red, on the gradual addition of a very dilute solution of sodium carbonate.

Pyrocatechin or *catechol*, $C_6H_6O_2$, is contained among the products of destructive distillation of several tannins and vegetable extracts. It crystallizes in short rectangular prisms, melts at 104° C. (219.2° F.), and boils at 245° C. (473° F.). It sublimes in thin laminæ, and dissolves easily in water, alcohol, and ether. Its aqueous solution is colored dark-green by ferric chloride, the color changing to violet on the addition of ammonia, sodium bicarbonate, or tartaric acid. The methyl ether of pyrocatechin is guaiacol.

Rubinic and japonic acids are names indefinitely applied to oxidation-substances of catechu and catechutannic acids.

Adulterants and Substitutes.—Cutch is subject to the most extensive adulteration. Although this exists chiefly in the tanning grades, we have seen some of the most disgusting specimens, of putrid and sickening odor, sold for pharmaceutical purposes. The official description should be rigidly applied. The chief adulterants, aside from the allowable 15 per cent. of accidental vegetable tissue, etc., are Than (see below), dried blood, ashes, sand, clay, and starch, and their detection is provided for in the official tests.

An *artificial catechu*, proposed by Rave (1873), may be obtained by slightly roasting powdered mahogany or allied woods, and then boiling with water; it is said to be serviceable in dyeing.

Pharmaceutical Preparations.—Compound Powder of Catechu, N. F.; Compound Tincture of Catechu, U. S. P.; Troches of Catechu, U. S. P. (See Gambir.)

Action and Uses.—Both the dark and the light catechu are employed in medicine; the former is more astringent, but the latter, being sweeter, is less disagreeable. It depends almost entirely for its virtues upon the tannic acid which it contains, hence it may be employed as an astringent to overcome relaxation of mucous membranes in general. It is an excellent remedy, especially when combined with chalk mixture, in the treatment of serous diarrhœa, and also in mucous diarrhœa after the patient has been thoroughly purged. It is also beneficial in the treatment of spongy gums, relaxation of the uvula, and simple pharyngitis attended with hoarseness. When thrown into the nostrils in the form of an infusion, it lends itself to the control of epistaxis, and when introduced into the uterus it may overcome passive hemorrhages from that viscus. In the form of an injection it is recommended in the treatment of uterine and vaginal leucorrhœa and in chronic gonorrhœa. Gambier catechu is largely used in the arts for dyeing purposes, and so possesses a value over and above its medicinal properties. "Cutch is an important dyestuff, yielding a color known as 'cutch-brown.' In this both the catechu and the catechutannic acid are active, but mostly the latter, with which a single process results in a color about as deep as that from the double process of the former."

The dose of catechu, in substance, is from 5 to 30 grains (0.30–2 Gm.); of the tincture, from ½ to 2 fluidrachms (2–8 Cc.).

Other Products.—Kath is obtained from the same wood-syrup which yields catechu, but is obtained by crystallization on twigs placed in the liquid, the pots being laid upon their sides, and is afterward pressed into cakes. It is largely catechin, and is entirely consumed in India, mostly for chewing with betel. As sold in the bazaars, it is in rectangular cakes, about 2 inches long. The outer hard crust, about ¼ inch thick, is mostly catechutannic acid. The inner soft and earthy portion contains about 36 per cent. of catechin and about 3 per cent. of wood and sand. A lot specially made for Dr. Watt, with the utmost care, yielded 62 per cent. of catechin, but yet contained 2 per cent. of sand and 4 per cent. of wood.

The bark of this tree and an extract obtained from it, are used for tanning.

The number of substances extracted from woods, barks, leaves, and fruits, used like catechu, and more or less resembling it, is now large. Those consisting of inspissated juices will be considered under Kino; those obtained from barks, because the barks themselves are articles of commerce, will be considered under Quercus. A number of astringent leaves and their extracts will be considered under their respective families. We here consider several wood-extracts closely allied in nature to catechu.

Than or *Thansha* is an extract obtained by boiling the bark of *Buceras Oliverii* (Brandis) Rusby (*Terminalia O.* Brandis.—Fam. *Combretaceæ*), and is considerably used in India to adulterate cutch. It is of a lighter and more brilliant color and semitransparent, and is very astringent in taste. Its composition appears extremely variable, the tanning material in different samples having been estimated at from 14 to 68 per cent. It may be detected by obtaining a precipitate from the suspected cutch by adding a solution of gelatin and then alum, and treating this precipitate with boiling water. That from pure cutch should yield but a faint-yellow color, while, if Than is present, a dark-red coloring-matter is extracted.

The barks of *B. pyrifolia* (Kurz.) Rusby (*Terminalia p.* Kurz.) and *B. tomentosa* (Mart.) Rusby (*Terminalia t.* Mart.) have also been used for the same purpose.

An extract of the bark of *Bruguiera gymnorhiza* Lam. (Fam. *Rhizophoraceæ*) has been recommended as a suitable substitute for catechu.

CAULOPHYLLUM.—Blue Cohosh.

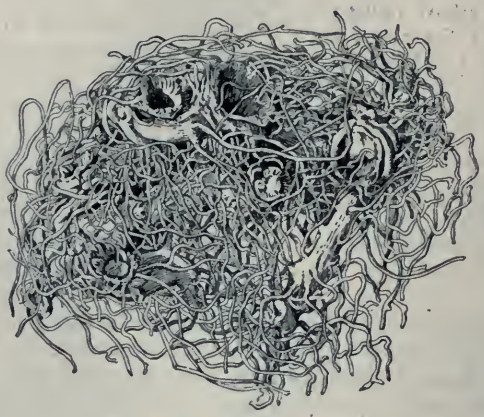
Pappoose-root, Squaw-root, Blueberry-root, Blue (or Yellow) ginseng.

The dried rhizome and roots of *Caulophyllum thalictroides* (L.) Mx. (*Leontice t.* L. —Fam. *Berberidaceæ*).

Origin.—A smooth and glaucous perennial with a simple stem, bearing near its apex a large sessile triternately compound leaf, with obovate 3- or 5-toothed or lobed leaflets. The greenish-yellow flowers, about 12 in number, form a terminal raceme, and produce capsules which are soon ruptured by the 2 globular seeds, these remaining enclosed in a blue fleshy integument, the mass resembling a blueberry. The plant is found in rich woodlands from Canada south to Carolina and Kentucky. It flowers in April and May.

Description.—Horizontal, 10 to 15 Cm. (4 to 6 In.) long and about 5 to 15 Mm. ($\frac{1}{5}$ to $\frac{3}{5}$ In.) thick, crooked and branched, usually slightly compressed from above downward; upper surface bearing broad, shallow cup-shaped scars, which are either slightly elevated or impressed; lower surface bearing very numerous elongated fine roots, which are crooked and matted, so as often nearly to conceal the rhizome; fracture tough and woody; sternutatory, but nearly inodorous; taste sweetish, bitterish, and acrid.

FIG. 95.



Caulophyllum (¾ Nat.).

Constituents.—The active principle is *leontin*, a saponin-like glucoside occurring in white feathery or silky crystals, soluble in boiling alcohol, slightly in cold alcohol, and freely in alkaline solution, and insoluble in water or chloroform. It is tasteless at first, but leaves an acrid after-taste. The drug contains also gum, starch, 2 resins, and *caulophylline*, a colorless, odorless, feebly tasting alkaloid, crystallizing with difficulty.

Substitutes.—*Jeffersonia* (see under BERBERIDACEÆ) is sometimes mistaken or substituted for caulophyllum.

Pharmaceutical Preparation.—FLUIDEXTRACT OF CAULOPHYLLUM (BLUE COHOSH), N. F.

Action and Uses.—This remedy is rarely employed by regular physicians. It is said by the eclectics to be an antispasmodic, diuretic, emmenagogue, and oxytocic, and is employed by them in the treatment of hysteria and uterine diseases. It is claimed by them that the drug will prevent threatened abortion, and again that it will cause normal uterine contractions when uterine inertia is present. A decoction made with 1 ounce (30 Gm.) of the root and 1 pint (480 Cc.) of water may be given in the dose of 1 or 2 fluidounces (30 or 60 Cc.). Its active principle, *leontin*, may be prescribed in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.).

CELASTRACEÆ.—The Spindle Tree Family.

Genera about 40, species about 400, consisting of shrubs and trees, widely distributed, except in the Arctic regions. Their economic importance is due chiefly to the medicinal properties, many being largely employed in domestic practice, several in professional medicine. A few species, like the *Gymnosporias* and *Parilla Malabarica* Dennst., contain sufficient tannin to render them useful as astringents. More, like EUONYMUS, contain glucosides, which impart to them highly important laxative or cathartic properties. A third and large group, represented by *Celastrus*, described below, contains glucosides of a saponin-like character, with corresponding properties.

Celastrus (*False* or *Climbing bittersweet*, *Staff-vine*, *Fever-twig*, *Waxwork*; also incorrectly called *Yellow-root* or *Orange-root*, E.; *Celaster*, G.; *Celastre*, Fr.) is the bark, especially of the root, of *Celastrus scandens* L., a tough woody twiner of eastern North America. It grows in the edges of thickets, especially in rocky and sunny situations and in fence-rows. The alternate, estipulate leaves are borne upon short, slender petioles, and are mostly 2 to 3 inches in length by 1½ to 2 inches broad, ranging from ovate to obovate, rounded at the base, shortly and abruptly acuminate and acute, finely and irregularly serrate with the teeth inturned, and reticulate-veiny. The short branchlets of the season terminate in racemes of small yellowish-green flowers, followed by globose fruits of the size of peas, which in the autumn rupture to

display the brilliantly scarlet-arilled seeds, and are much used in country districts for the decoration of picture-frames, mirrors, etc. The stem-bark is brownish or purplish-gray. The root-bark is of a dark orange-brown color, nearly smooth, and occurs in small quills. Internally, the surface is whitish and finely striate. The transverse section exhibits an outer tough, pale-brown band, a middle bright orange-red band, and an inner nearly white fragile band in concentric layers. The outer band separates readily. The bark possesses little odor and a bitter-sweet taste, afterward acrid. Besides ordinary plant-constituents, starch, gum, a little volatile oil, an acid and a neutral resin, it contains a white crystalline body, the nature of which has not been determined. The yellow coloring-matter is related to carotin. There is also a slight amount of a caoutchouc-like substance.

There are nearly 30 species in the genus *Celastrus*, several of them similarly employed, while others have fanciful uses. The seeds of *C. paniculata* W., of the East Indies, are stimulant, and are employed as an aphrodisiac. The leaves of the African species *C. serratus* Hochst. (*C. obscurus* A. Rich), *Add-add*, are used as an antiperiodic. In Arabia and adjacent parts of Africa, the leaves of *Catha edulis* Forsk. (*Celastrus e.* Vahl.) are used as a substitute for tea, under the names *Khat*, or *Kat*, and *Cafta*. They have been found to contain the peculiar alkaloid *katrine*, which is said to have a poisonous action, similar in many respects to that of cocaine. It is present in very small quantity, leaves from Aden yielding only 0.076 per cent., those from Harrar 0.034 per cent. It was extracted by ammoniated chloroform and purified with difficulty by conversion into the hydrobromide and regeneration. Its salts give precipitates with the usual alkaloidal reagents, but only when present in fairly strong solution. Associated with it is a new caoutchouc substance ($C_{10}H_{17}O$), which softens at 50° C. (122° F.), also traces of a volatile oil which has a powerful odor, darkens on keeping, and ultimately deposits small crystals. The oil is lighter than water. In the Argentine, a number of empirical uses are made of the leaves of *Maytenus vitis-idæa* Griseb. (*Colquiyuya, Capia Gangona, Chalpan*, etc.). Celastrus is not commonly employed in medicine, but in domestic practice is recommended as an emetic, diaphoretic, and antisyphilitic. It has been used also in the treatment of chronic hepatic affections attended with obstruction.

CERA, *U. S., Br., P. G., Fr., It., Port.*—Wax.

Wachs, G.; *Cire*, Fr.; *Cera*, It., Sp.

Official Varieties.—1. Cera Flava, U. S., Br., P. G. (*Yellow wax, Gelbes Wachs*, G.; *Cire Jaune, C. d'Abeilles.* Fr.; *Cera Citrina*, Russ.; *Cera Vergine, C. Gialla*, It.; *Cera amarilla*, Sp.; *Cera animalis, C. de Abolhas*, Port.). A solid substance prepared from the honeycomb of the hive-bee or honey-bee—*Apis mellifica* L. (Order *Hymenoptera*).

2. Cera Alba, U. S., Br., P. G.—*White wax* (*Weisses Wachs*, G.; *Cire blanche*, Fr.; *Cera bianca*, It.; *Cera blanca*, Sp.; *Cera Branca*, Port.). Yellow wax bleached.

The common honey-bee presents a number of well-marked varieties, or species as regarded by some zoölogists, in different countries, but the differences in the wax produced, except from incidental causes, are unimportant. The wax, of which the comb is made, is secreted between the rings of the animal's body. After the removal of the honey, by draining or by a centrifugal machine, followed by expression, the comb is melted in hot water, and most of the impurities allowed to separate by subsidence, the decanted product being *yellow wax*. A superior article is produced by filtering the melted wax. To prepare yellow wax for bleaching into *white wax*, it is reduced to a very thin bulk by rolling or grating, and is then kept exposed, in a moistened condition, to light and air. That bleached by chlorine and other chemicals is classed as inferior.

Description.—*Cera Flava:* A yellowish to brownish-yellow solid, having an agreeable, honey-like odor, and a faint, balsamic taste. Specific gravity, 0.951 to 0.960 at 25° C. (77° F.). Melting-point, 62° to 64° C. (143.6°–147.2° F.). It is brittle when cold, and when broken presents a dull, granular, not crystalline fracture. By the heat of the hand it becomes plastic. Yellow wax is insoluble in water, sparingly soluble in cold alcohol, but almost completely in boiling alcohol. It is completely soluble in ether, chloroform, and in fixed and volatile oils; partially soluble in cold benzene or carbon disulphide, and completely in these liquids at a temperature of 25° to 30° C. (77°–86° F.). If 1 Gm. of yellow wax be boiled for half an hour with 35 Cc. of a 15 per cent. aqueous solution of sodium hydroxide, the volume being preserved by the occasional addition of water, the wax should separate on cooling without rendering the liquid opaque, and no precipitate should be produced in the filtered liquid by hydrochloric acid (absence of fats or fatty acids, Japan wax, resin); nor should the same reagent produce a precipitate in water which has been boiled with a portion of the wax (absence of soap). If 5 Gm. of yellow wax be heated in a flask for 15 minutes with 25 Cc. of sulphuric acid to 160° C. (320° F.), and the mixture then diluted with water, no solid,

wax-like body should separate (absence of paraffin). Yellow wax saponified by alcoholic potassium hydroxide test-solution should show a saponification value of from 90 to 96.

Cera Alba: A yellowish-white solid, somewhat translucent in thin layers, having a slightly rancid odor and an insipid taste. Specific gravity, 0.950 to 0.960 at 25° C. (77° F.). Melting-point, about 64° to 65° C. (147.2°–149° F.). In other respects white wax has the characteristics of, and should respond to, the reactions and tests given under yellow wax (see Cera Flava).

Constituents.—Yellow wax contains some aromatic and coloring-matters, which vary somewhat in wax from different localities, and are destroyed by the bleaching process; they are partly dissolved by cold alcohol, together with a very small quantity of *cerolein*, which resembles a fat in appearance. Boiling 90 per cent. alcohol dissolves 10 to 20 per cent. of *cerin* or *cerotic acid*, $C_{27}H_{54}O_2$, which exists likewise in Chinese wax, is crystalline, and fuses in its pure state at about 81° C. (177.8° F.). Schalfeief (1876) succeeded, by fractional precipitation with lead acetate, in separating it into several acids, one having the composition $C_{34}H_{68}O_2$. Repeated boiling of wax with alcohol leaves yellow *myricin* behind, which is *myricyl palmitate*, $C_{30}H_{61}.C_{16}H_{31}O_2$; when pure, it forms feathery crystals, has the fusing-point at 72° C. (161.6° F.), is very sparingly soluble in alcohol, more freely in ether and oil of turpentine, and is with difficulty saponified by boiling with concentrated solution of potassium hydroxide. The principle to which bleached wax owes its rancid odor has not been ascertained.

Action and Uses.—Wax possesses no truly medicinal properties, but was formerly employed as a protective and soothing agent to the mucous membranes in the treatment of diarrhœa and dysentery. At present it is used to some extent for the same purposes. Its principal use now is in the preparation of elegant pharmaceuticals and surgical dressings.

Vegetable Waxes.—These are very numerous, being responsible for the whitish "bloom" on grapes, pumpkins, and other fruits, and for the glaucescence of the herbage of very many plants. The exudation is usually too scanty to allow of collection, but the reverse is true in a number of cases, in which such waxes are important commercial products. Their composition is similar to that of cera, and they may be successfully substituted for many of the uses of the latter. They have been recommended in the treatment of diarrhœa and dysentery. They are also used to prepare wax candles. The internal dose is stated to be 1 drachm (4 Gm.), several times daily.

Japan Wax is produced by a number of species of *Rhus*. It is moulded into cakes which appear of a whitish or pale-yellowish color, the surface being netted with fine cracks. T. Wall gives the specific gravity as about 0.980, the melting-point 54° C. (129.2° F.), and the saponification number 220.98. This article also is subject to much adulteration, especially with starch, often to the extent of 25 or 30 per cent.

Carnauba Wax is a very peculiar substance, the product of *Copernicia cerifera* (Arruda) Mart. (*Corypha c.* Arruda.—Fam. *Palmaceæ*), the Brazilian *Wax palm*, one of the most useful of trees, supplying, as do so many of the palms, a great variety of products. It was reported that during the first half of 1894 the following products of this tree were exported from Aracaty, Brazil: 443,500 hats, 73,360 mats, 120,000 brooms, 20,000 pieces of cordage, nearly 25,000 pounds of wax, and about 30,000 pounds of candles made from the same, and nearly 150,000 pounds of fruit-stones, the pulp having been consumed at home, besides some minor products. Starch, sugar, and a cork-substitute are also yielded. The root is a valued diuretic and reputed alterative in its own home, and has been so offered in this country. The wax is exuded by the young leaf-surfaces, and collects upon the trunk in drops and masses. It is also collected by beating off, in the form of powder, from the young leaves. It occurs in cakes of a pale-yellow, sometimes greenish color, and is hard and brittle, with a resinous fracture and luster. It requires a heat of about 85° C. (185° F.) to melt it. It consists chiefly of melyssyl alcohol ($C_{30}H_{62}O$). It is too hard for the ordinary uses of wax, unless mixed with some other substance. For candle-making, it is mixed with tallow, and for other purposes with beeswax.

Ceroxylon andicolum Humb., an Andean palm, and others of this genus, yield a similar wax (*Ocuba wax*).

Myrica Wax is obtained from the fruits of several very similar species of *Myrica* (illustrated under Myrcia), especially from *M. cerifera* L. and *M. Carolinensis* Mill., the American *Vegetable wax* or *Bayberry tallow*, and *M. Jalapensis* (*Arbol de la Cera*), much used for candle-making in tropical America under the name of *Cera vegetal*, but very little exported. It is a pale-green wax, with a distinct aromatic odor and a bitterish taste, and melts at about 45° C. (113° F.), the melting-point rising as it ages.

Ocotilla Wax is derived from the bark of *Fouquiera splendens* Eng. (Fam. *Tamariscineæ*), the *Arbol de Cera* of the Mexicans.

CERATA.—Cerates.

Cérats, Céréolés, Elaeocéréolés, Fr.; *Cerate, Wachssalben*, G.

The term cerate is applied to a class of unctuous preparations which in consistence are about intermediate between ointments and plasters, sufficiently soft to be spread at the ordinary temperature, and at the same time firm enough to adhere to the skin without melting. They are composed of wax, united with a fatty or oleoresinous substance, and to obtain them of proper consistence 2 parts of wax require about 3 parts of fixed oil, 4 parts of lard, or 1 part of soft turpentine. In preparing cerates, the wax or resin should be melted first by the aid of a water-bath or otherwise carefully regulated heat. When thoroughly melted, the warm oil or lard should be added in quantities small enough not to congeal the melted portion, and after all the ingredients have been liquefied and the vessel removed from the fire the mass should be well stirred or beaten with a spatula, to prevent the partial separation of the least fusible substances and to insure perfect homogeneousness of the preparation. It is well to continue this manipulation until the temperature has been reduced to that of the room, but artificial refrigeration should not be applied until after the mass has thickened, and then only if vigorous stirring (or, better still, trituration) is kept up. With this in view, the soft cerate may be transferred to a mortar previously warmed by hot water, or the whole process may be completed in a well-enamelled iron vessel with a rounded bottom if a pestle fitting the curve of the latter be used. Straining is best avoided, and all the materials should therefore be free from dust and other foreign bodies. Powders, cantharides excepted, are gradually added while the cerate is merely soft enough to permit the whole to be uniformly mixed, and liquids should be previously warmed to 40° or 45° C. (about 110° F.). In dispensing cerates with extracts, the latter should be previously rubbed with water in a mortar to a uniform thin paste, which should then be mixed with the cerate, added in small portions until the extract has been thoroughly incorporated; the remaining cerate may then be added in larger quantities.

Cerates should be kept in a cool place, where the temperature is not likely to rise much above 15° C. (59° F.), but even then those made with white wax, owing to its incipient rancidity, are liable to become rancid, while such as contain yellow wax keep unaltered for a much longer period. Some cerates, which are sufficiently firm, may be conveniently kept and dispensed in the form of square cakes, which are easily made by pouring the fused and nearly cool cerate into square moulds made of oiled or paraffin-paper and placed upon a flat slab. After the cerate has solidified, it is without difficulty removed from the paper and cut into pieces of any desired size or weight.

The name *steatina, steatins*, has been suggested by Mielck (1881) for a class of preparations which are of about the same consistence as cerates, but the base of which is suet, combined with either expressed oil of nutmeg, with wax, or with lead plaster deprived of glycerin and water.

Of late years, cerates have been largely superseded, especially in Europe, by *dermatologic pastes and glycerogelatins*. The former are mixtures of the medicinal agents with starch, dextrin, or kaolin, and glycerin, soft soap, petrolatum, or lard, and are intended chiefly for antiseptic, astringent, or germicidal effects. As a general vehicle for the preparation of these pastes, a mixture of dextrin, glycerin, and distilled water, equal parts by weight, may be brought into solution with the aid of heat, and sufficient water finally added to restore any loss by evaporation. Ichthyol, naphtol, resorcin, salicylic acid, sulphur, and zinc oxide are the more important remedial agents used in the form of pastes, the proportions being varied to suit particular cases. The glycerogelatins are firmer than the pastes, and require to be melted before they can be applied to the affected parts, which latter is done by means of a soft brush. The vehicle consists of a mixture of gelatin, glycerin, and water, made in proportions ranging from 5, 20, and 65 parts to 15, 45, and 25 parts of the respective constituents. As medicating agents, chrysarobin, ichthyol, iodoform, resorcin, salicylic acid, and zinc oxide are added singly or in combination.

Another form of modern dermic medication is by means of *pencils*, of which the following formula serves as an example: salicylic acid, 10 parts; powdered tragacanth, 5 parts; starch, 30 parts; dextrin, 35 parts; sugar, 20 parts; distilled water, sufficient to make a paste, which is rolled out into rods about 5 Mm. ($\frac{1}{5}$ In.) in diameter and 5 Cm. (2 In.) in length. The pencils are dried at ordinary temperature on parchment-paper and wrapped in tin-foil.

CERATUM, *U. S.*—Cerate.

Unguentum cereum, P. G.; *Ceratum simplex, Ceratum adipis.—Simple cerate*, E.; *Cérat simple*, Fr.; *Einfaches Cerat, Wachssalbe*, G.

Preparation.—White wax, 300 Gm.; white petrolatum, 200 Gm.; benzoinated lard, 500 Gm.; to make 1000 Gm. Melt the white wax, add the white petrolatum, then the benzoinated lard, continuing the heat until the mixture is liquefied, and stir it constantly until it congeals.—U. S.

If 3 ounces of white wax, 2 ounces of white petrolatum, and 5 ounces of benzoinated lard be used, the official proportions will be preserved. The simple cerate of the French Codex is composed of 1 part of white wax to 3 parts of expressed oil of almonds; and the wax ointment, P. G., of 3 parts of yellow wax to 7 parts of olive oil.

In southern latitudes, and during the heated season elsewhere, 10 per cent. of the benzoinated lard should be replaced by an equal quantity of white wax.

Action and Uses.—Simple cerate is used as a base for applying medicinal substances to the skin, and as a soothing, emollient dressing.

CERATUM CAMPHORÆ, *U. S.*—Camphor Cerate.

Unguentum (Pomatum, Fr. Cod.) *camphoratum. Pommade camphrée*, Fr.; *Kampfersalbe*, G.; *Cerata alcanforada*, Sp.

Preparation.—Camphor liniment, 100 Gm.; white wax, 350 Gm.; white petrolatum, 150 Gm.; benzoinated lard, 400 Gm.; to make 1000 Gm. Melt the white wax with the aid of a gentle heat; add the white petrolatum, then the benzoinated lard, and continue the heat until the mixture is liquefied. While the mixture is cooling, add the camphor liniment, and stir the mixture occasionally until it has become cold.—U. S.

If 3½ ounces of white wax, 1½ ounces of white petrolatum, 4 ounces of benzoinated lard, and 1 ounce of camphor liniment be used in place of the prescribed metric weights, the proportions will not be changed.

Melt at a moderate heat white wax 1 part and lard 9 parts; add powdered camphor 3 parts, and stir until the camphor is dissolved and until the ointment becomes cool.—Fr. Cod.

The consistence of the camphor cerate, U. S. P., is softer than that of most other cerates. It contains 2 per cent. of camphor.

Medical Uses.—Camphor cerate is commonly employed as a basis for other remedies. It may be applied alone as a stimulating dressing to chronic ulcers.

CERATUM CANTHARIDIS, *U. S.*—Cantharides Cerate.

Emplastrum cantharidis, Br.; *Emplastrum vesicans*, Fr. Cod.; *Emplastrum cantharidum ordinarium*, P. G.; *Emplastrum epispasticum s. vesicatorium. Emplastrum lyttæ. Blistering cerate or plaster*, E.; *Emplâtre de cantharides, Emplâtre vésicatoire*, Fr.; *Spanischfliegen-Pflaster, Blasenpflaster*, G.; *Pomalum di cantaridi*, It.

Preparation.—Cantharides in No. 60 powder, 320 Gm.; yellow wax, 180 Gm.; rosin, 180 Gm.; lard, 170 Gm.; liquid petrolatum, 150 Gm.; to make 1000 Gm. Mix the cantharides with the liquid petrolatum, and set the mixture aside, well covered, in a warm place, for 48 hours. Then add it to the yellow wax, rosin, and lard, previously melted and strained through muslin, and keep the mixture in a liquid condition by means of a water-bath, stirring occasionally for 1 hour. Then remove it from the bath and stir it occasionally until it is cool.—U. S.

If avoirdupois weight is more convenient, the following quantities should be used: Cantharides in No. 60 powder, 4 ounces; yellow wax, 2¼ ounces; rosin, 2¼ ounces; lard, 2 ounces; liquid petrolatum, 2 ounces; to make 12½ avoirdupois ounces.

Take of cantharides, in powder, 3½ ounces; yellow wax, 2 ounces; lard, 2 ounces; resin, 2 ounces; soap plaster, ½ ounce. Melt the resin, add the soap plaster, and afterward the wax and lard. Sprinkle the cantharides into the melted mixture and stir continuously while cooling.—Br.

The object of previous treatment of the cantharides with liquid petrolatum is to facilitate the subsequent solution of cantharidin in the fats, as liquid petrolatum is known

to exert a ready solvent effect upon the active blistering agent. The process of the U. S. P. always insures an effectual blistering cerate, provided the cantharides are of good quality. It is important that the heat be not raised above 100° C. (212° F.), since cantharidin would volatilize with the watery vapors extricated from the powder, and, while weakening the cerate, vesication of the operator's face and hands would be apt to occur.

The blistering cerate of the U. S. P. contains 32 per cent., that of the Br. P. 35 per cent., of the Fr. Cod. 33⅓ per cent., and that of the P. G. 25 per cent. of powdered cantharides.

Action and Uses.—The medical uses and properties of this remedy are discussed under Cantharides.

CERATUM CETACEI.—Spermaceti Cerate.

Unguentum Cetacei, Br.; *Emplastrum spermatis ceti, Ceratum labiale album.*—*Spermaceti ointment*, E.; *Cérat de blanc de baleine, Onguent blanc*, Fr.; *Walrat-Cerat*, G.; *Cerato de Bell*, Sp.

Preparation.—Take of spermaceti, 20 ounces; white wax, 8 ounces; almond oil, 72 ounces; benzoin, in coarse powder, 2 ounces. Melt together the spermaceti, wax, and almond oil; add the benzoin, and continue the application of heat for 2 hours, frequently stirring the mixture. Strain and stir the ointment until cold.—Br.

Spermaceti cerate is no longer official in the U. S. P. The 1890 formula called for spermaceti, 10 Gm.; white wax, 35 Gm.; and olive oil, 55 Gm.; to be melted together, and then constantly stirred until cool.

The following preparation is often used for chapped lips:

Ceratum Rosatum.—*Rose cerate, Lip salve*, E.; *Cérat à la rose, Pommade pour les lèvres*, Fr.; *Lippenpomade*, G.—Melt together at a moderate heat white wax, 50 Gm., and expressed oil of almond, 100 Gm.; when partly cooled add carmine, 0.5 Gm., previously rubbed up with a little of the oil; stir well, and finally add essential oil of rose, 0.5 Gm.—Fr. Cod.

Medical Uses.—Spermaceti cerate is employed as a basis for active remedies, and as a mild dressing for abrasions, blisters, and ulcers.

CERATUM PLUMBI SUBACETATIS, *U. S.*—Cerate of Lead Subacetate.

Unguentum glycerini plumbi subacetatis, Br.; *Unguentum plumbi*, P. G.; *Ceratum cum subacetate plumbico*, Fr. Cod.—*Goulard's cerate, Ointment of glycerin of lead subacetate*, E.; *Cérat de saturné, C. saturné, C. de Goulard*, Fr.; *Bleisalbe, Bleicerat*, G.

Preparation.—Solution of lead subacetate, 20 Gm.; wool-fat, 20 Gm.; paraffin, 20 Gm.; white petrolatum, 38 Gm.; camphor, 2 Gm. To the melted wool-fat in a warm mortar gradually add the solution of lead subacetate, and incorporate it by slow trituration. To the mixture add the white petrolatum and paraffin, previously melted, and in which the camphor has been dissolved; mix thoroughly until homogeneous.—U. S.

If the above weights be considered as grains and multiplied by 5, the resulting product will weigh a trifle over 1 troy ounce.

The Br. P. directs that 1 ounce of glycerin of lead subacetate be incorporated with a previously prepared mixture of 1½ ounces of hard paraffin and 3½ ounces of soft paraffin, whereas the P. G. orders 1 part each of solution of lead subacetate and wool-fat to be mixed with 8 parts of paraffin ointment (solid paraffin, 1; liquid paraffin, 4).

The official formula will yield an unobjectionable preparation and is a great improvement on that of 1890, inasmuch as the tendency to become rancid has been overcome by elimination of the cerate. It must not be overlooked that the wool-fat directed in the formula is the anhydrous variety. The finished product contains about 5 per cent. of lead subacetate and 2 per cent. of camphor.

Medical Uses.—This remedy is employed as an astringent application to abrasions, blisters, ulcers, burns, chilblains, and inflammatory eruptions of the skin. It should not be applied over extensive raw surfaces, lest a poisonous amount be absorbed.

CERATUM RESINÆ, *U. S.*—Rosin Cerate.

Unguentum resinæ, Br.; *Unguentum basilicum*, P. G.; *Unguentum tetrapharmacum.*—*Resin ointment, Basilicon ointment*, E.; *Cérat de résine anglais, Onguent basilicum*, Fr.; *Harzsalbe, Königssalbe, Zugsalbe*, G.

Preparation.—Rosin, 350 Gm.; yellow wax, 150 Gm.; lard, 500 Gm.; to make 1000 Gm. Melt them together at a moderate heat, strain the mixture through muslin, and allow it to cool without stirring.—U. S.

If 7 ounces of rosin, 3 ounces of yellow wax, and 10 ounces of lard be melted together, the official proportions will be preserved.

Take of resin in powder, 8 ounces; yellow wax, 8 ounces; olive oil, 8 ounces; lard, 6 ounces.—Br.

The impurities always present in the rosin necessitate the straining of this and the following cerate. By melting and straining the rosin alone the purified rosin may be kept on hand and subsequent straining avoided. The formulas of the French and German pharmacopœias differ considerably from the foregoing, the former ordering black pitch, the latter turpentine, among the ingredients.

Medical Uses.—Rosin cerate is locally applied as a stimulant to sluggish ulcers following burns, scalds, and blisters. It may also be applied to excoriations and chilblains. The compound rosin cerate is employed for the same purposes, but is somewhat more stimulating than the former.

CERATUM RESINÆ COMPOSITUM, *U. S.*—Compound Rosin Cerate.

Deshler's salve, E.; *Cérat de résine composé*, Fr.; *Zusammengesetzte Harzsalbe*, G.

Preparation.—Rosin, 225 Gm.; yellow wax, 225 Gm.; suet, 300 Gm.; turpentine, 115 Gm.; linseed oil, 135 Gm. Melt the rosin, yellow wax, turpentine, and suet; to this add the linseed oil, and continue the heat until the mixture is liquefied; then strain through coarse muslin, and stir until it begins to congeal.—U. S.

To make about 1 troy ounce of the cerate, use 113 grains of rosin, 112 grains of yellow wax, 150 grains of suet, 58 grains of turpentine, and 67 grains of linseed oil, and proceed as directed above.

Compound rosin cerate was official in the U. S. P. of 1870, but was omitted from the editions of 1880 and 1890. It has a tendency to become tough in consequence of oxidation of the linseed oil, and should not be kept on hand in large quantities. As pointed out by S. A. D. Sheppard in 1878, the cerate keeps better if made with olive oil or liquid petrolatum in place of linseed oil.

Uses.—Compound rosin cerate is used for similar conditions as rosin cerate when a more stimulating effect is desired than that produced by the latter preparation.

CEREVISIÆ FERMENTUM.—Beer Yeast.

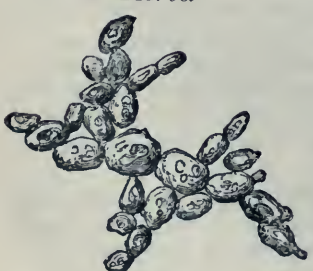
Yeast, Brewers' yeast, E.; *Bierhefe*, G.; *Levûre de bière*, Fr.; *Levadura de cerveza*, Sp.

The ferment obtained in brewing beer.

Origin.—The history of the discovery of the vegetable nature of yeast is too well known to require review.

There are two varieties of brewers' yeast—the *upper* or *top yeast*, and the *lower* or *bottom yeast* (*Oberhefe* and *Unterhefe* of the Germans). The former is the kind most generally met with in the United States, and is a viscid, semifluid, frothy mass of a peculiar odor and bitter taste, and containing oval or globular microscopic cells from which smaller ones are developed by budding; it appears upon the surface of the fermenting liquid, kept at a temperature ranging between about 15° and 20° C. (59° and 68° F.). But wort fermented with top yeast at a temperature near or below 10° C. (50° F.) will produce both top and bottom yeast, the latter being reproduced solely by the fermentation from below (*Untergährung*, G.) at a temperature of about 9° C. (48° F.) and less. It consists of various-sized cells, differing from those of the top yeast in not having any small cells attached, and appears to be reproduced from isolated spores instead of by budding. The cell-membrane consists of a kind of cellulose, and encloses protein compounds.

Fig. 96.



Yeast-cells.

At a temperature below 5° C. (41° F.) the yeast-plant ceases to vegetate, but it

may be exposed to a cold of —60° C. (—76° F.) without being killed. At a temperature of 75° C. (167° F.) and above, it loses its vitality unless water be absent, when it will not be destroyed by a temperature of 100° C. (212° F.) or more. On removing most of the water by pressure the *dry yeast* of commerce is obtained, which may be kept in this condition without material alteration. *Vienna yeast* is the same article, and is stated by Vigla (1871) to be made by fermenting a wort obtained from a mixture of maize and rye with barley malt, skimming off the froth, draining, and subjecting it to pressure. So-called *artificial* or *patent yeast* is made either of flour dough with the addition of a little yeast, or of an infusion of hops to which malt is subsequently added. Soxhlet and Pasteur (1876) proved that the only effect of hops, when thus used, is to impart bitterness to the mass and somewhat delay the spoiling of the product.

When yeast is added to a solution of pure sugar, active fermentation takes place, the yeast being gradually rendered inert, but in the presence of albuminous matters in the saccharine liquid the yeast-plant is continually reproduced and augmented.

Constituents.—The researches of Büchner have proved that the entire activity of yeast depends upon enzymes or ferments, in which it is very rich. Other investigators showed the presence of *invertase* (of which *invertin* was a very impure form), diastase, and maltase; but Büchner discovered the most important one, *zymase*, which differs from the others in its inability to escape outside of the cell through the pores in its wall. It therefore has to be extracted by the most laborious and thorough physical disintegration of the cell body, followed by very high pressure. For a long time its enzymic nature was questioned, it being claimed that it consisted of the living, even though disintegrated protoplasmic substance. But the activity was found to be preserved after various forms of treatment entirely destructive to such vitality, with chloroform, by high desiccation, and by heat. Zymase after extraction (of course, in an impure form) very quickly disappears, apparently through the indirect effects of the one or more proteolytic ferments present. This loss has been found very difficult of prevention, though thorough desiccation has been found capable, under the most favorable conditions, of preserving its activity for several months. Many experimenters are now (1902) at work in attempts to manufacture a stable form of it for use as a yeast substitute.

Action and Uses.—Because of its highly stimulant properties, yeast was at one time strongly recommended in the typhoid state occurring during the course of many of the acute infectious fevers. It was usually prescribed in the dose of from ½ to 1 pint daily. At present its use has largely been abandoned.

In the dose of 1 ounce (30 Gm.), 3 times daily, the drug has also been employed in scurvy, purpura, furunculosis, dysentery, and infantile diarrhœa, but many more efficient remedies for these conditions have succeeded it. It has been used in the treatment of diabetes mellitus.

As a local application to phagedenic sores, gangrene, and similar conditions, it is still employed to some extent, but antiseptic fomentations have largely taken its place.

The yeast poultice is somewhat stimulating, and is thought to possess slight antiseptic properties which are due to the generation of carbon dioxide.

CERII OXALAS, *U. S., Br.*—Cerium Oxalate.

Cerium oxalicum.—*Oxalate de cerium*, Fr.; *Oxalsaures Ceroxydul, Ceroxalat*, G.

Formula, $Ce_2(C_2O_4)_3.9H_2O$. Molecular weight, 701.34.—Br.

It consists chiefly of a mixture of cerium, didymium, praseodymium, and lanthanum oxalates, and other rare earths of this group.—U. S.

Origin.—The metal cerium was discovered in 1803 in a Swedish mineral simultaneously by Klaproth and by Berzelius and Hisinger. The last-named chemists called the mineral *cerite*, after the planet Ceres, then recently discovered, and the metal *cerium*. Mosander (1839 and 1840) observed in the supposed pure cerium oxide the oxides of 2 other hitherto unknown metals, which received the names of *lanthanum* and *didymium*. The 3 metals exist together as silicates in cerite and allanite, the latter mineral being found in Scandinavia and in the States of New York and Pennsylvania. Cerium also exists along with a small per cent. of thorium in the mineral *monazite*, which occurs in considerable quantity in North Carolina and Brazil. Monazite, which is essentially a phosphate, has become of great industrial importance, and it is the chief source of thorium oxide, which, with 1 per cent. of cerium oxide, constitutes the Welsbach mantles, now so generally employed because of the intense light given out when heated. It is probable

that the cerium oxalate of commerce, which, although used medicinally, consists of a mixture of oxalates of cerium, lanthanum, and didymium, is more or less a by-product in the preparation of thorium salts. Cerium forms two series of salts, known as cerous and ceric. In the former, the salts are derived from *cerous oxide* or cerium sesquioxide, Ce_2O_3, in which the metal is trivalent; in the latter they are derived from *ceric oxide* or cerium dioxide, CeO_2, in which the metal is tetravalent. The dioxide is yellow and stable at high heat. The atomic weight of cerium is 140 (Brauner, *Chem. News*, 1895; and Muthmann, *Ber.*, 1898). The chemistry of the cerite earths is fully treated in an article, "Beiträge zur Kenntniss der Ceriterden," by O. N. Witt and Walter Theel (*Ber.*, 1900).

Preparation.—To obtain cerium oxalate, F. F. Mayer (1860) recommended the following process: The powdered mineral is heated with concentrated sulphuric acid, the dry mass ignited, then dissolved in dilute nitric acid, and treated with hydrogen sulphide to remove copper, etc. A little hydrochloric acid is added to prevent precipitation of calcium salt, and the cerite metals are precipitated as oxalates by oxalic acid. The precipitate is mixed with magnesium carbonate, the mixture calcined to decompose the oxalates, the residue dissolved in a small portion of concentrated nitric acid, and the solution thrown into a large quantity of water containing about 0.5 per cent. of sulphuric acid. Lanthanum and didymium remain in solution, together with the magnesium and a little cerium, most of which is precipitated as yellow *ceric* sulphate; the latter is dissolved in sulphuric acid and reduced to cerous sulphate by sodium thiosulphate, when the oxalate may be precipitated by oxalic acid. Ouvrard has succeeded in freeing cerium entirely from lanthanum and didymium by fusing the nitrates with 10 times their weight of saltpeter. In the technical separation of cerium from other earths, ammonium persulphate is used.

Properties and Tests.—Cerium oxalate is a white, granular, inodorous, and tasteless powder, permanent in the air, insoluble in the simple solvents, but soluble in diluted sulphuric and hydrochloric acids without effervescence (absence of carbonates); and the solution of the salt (1 in 20) in diluted hydrochloric acid, should not be colored or made turbid by an equal volume of fresh hydrogen sulphide solution, when standing corked at 35° C. (95° F.) for at least half an hour (absence of heavy metals). When heated to redness, it is decomposed, leaving a residue of reddish-brown ceric and other rare earth oxides, equal to not less than 47 per cent. of the salt. On boiling the salt with potassium hydroxide test-solution, white hydroxides are left as insoluble residue, which gradually turns yellow by oxidation, while in the filtrate, supersaturated with acetic acid, calcium chloride test-solution will produce a white precipitate insoluble in acetic, but soluble in hydrochloric acid. If the brown residue left after heating be dissolved in concentrated sulphuric acid, and a small crystal of strychnine added, a deep-blue color appears, which rapidly changes to purple and then to red. Ammonium carbonate test-solution precipitates white cerous carbonate, which is somewhat soluble in an excess of the reagent. If 0.1 Gm. of cerium oxalate be dissolved in 1 Cc. of sulphuric acid, and 2 Cc. of potassium sulphate test-solution be added, small colorless crystals of cerium-potassium sulphate will be deposited after some time. The other rare earths are precipitated as double sulphates at the same time. 5 Cc. of a 10 per cent. solution in diluted hydrochloric acid should not respond to the modified Gutzeit's test for arsenic (given under ARSENI TRIOXIDUM). On boiling the salt with potassium hydroxide test-solution and filtering, no precipitate should be produced in the filtrate either by ammonium chloride test-solution (absence of aluminum) or by ammonium sulphide test-solution (absence of zinc).—U. S. When incinerated, it loses 53 per cent. of its weight.—Br. Power and Shedden state that pure cerium oxalate crystallizes with 10 molecules of water, instead of 9 molecules as given in the pharmacopœias (*Jour. Soc. Chem. Ind.*, vol. xix. No. 7). Knorre has observed a characteristic and very delicate test for cerium, which consists in gently heating 0.1 Gm. of cerium oxalate with 0.5 Cc. of concentrated sulphuric acid till effervescence ceases, adding 10 Cc. of water and 1 Gm. of ammonium persulphate when the liquid is cool, then heating to boiling for a minute or so, when a bright-yellow color will be produced (oxidation to ceric salts).

Action and Uses.—This drug was first proposed as a remedy for the vomiting of pregnancy. Given either alone or in conjunction with bismuth subnitrate, it is useful in the treatment of reflex vomiting; for example, that resulting from severe paroxysms of coughing or associated with uterine disorders and displacements. It may also be of value

in simple gastric acidity, and is believed by some to be of service in the treatment of gastric ulcer and cancer. Prof. Simpson also recommended this drug as a nerve tonic, and employed it with asserted success in the treatment of chorea. The dose is from 2 to 10 grains (0.12–0.60 Gm.) several times a day. It may be prescribed in pill or in powder.

Cerium nitrate is believed to be a nerve tonic, and in doses of 1 or 2 grains (0.05–0.10 Gm.), gradually increased, is employed in chorea, chronic vomiting, gastrodynia, and pyrosis.

Other Salts of Cerium.—Cerii Carbonas, $Ce_2(CO_3)_3.9H_2O$ (molecular weight, 617.97), is prepared by precipitating cerous sulphate (see above) with ammonium carbonate. The white flocculent precipitate changes to scales of a silvery luster, which are insoluble in water and contain 52.4 per cent. of cerous oxide and 26.2 per cent. of water of crystallization.

Cerii Bromidum.—On dissolving cerous carbonate in hydrobromic acid and evaporating the solution, Bullock (1871) obtained a chocolate-colored, sweet, styptic mass which is freely soluble in alcohol, but leaves an insoluble residue of cerous compound on treatment with water. Cerium chloride and iodide are likewise readily decomposed, the former becoming yellow, the latter brown, on exposure to the air.

Cerii Nitras. $Ce(NO_3)_3.6H_2O$. Molecular weight, 431.19.—It is conveniently made by the mutual decomposition of cerous sulphate and barium nitrate, and filtering the cerous nitrate from the insoluble barium sulphate. The salt is very deliquescent, crystallizes in colorless prisms or scales, contains 37.9 per cent. of cerous oxide, and is freely soluble in water and alcohol.

CETACEUM, *U. S., Br., P. G.*—Spermaceti.

Blanc de baleine, Cétine, Ambre blanc, Fr.; *Walrat*, G.; *Cetina, Cianco di balena*, It.; *Esperma de ballena*, Sp.; *Espermaceti*, Port.

Nearly pure cetin, obtained from the head of the sperm whale, *Physeter macrocephalus* (*Catodon m.* Lacep.—Order *Cetaceæ*).

A peculiar, concrete, fatty substance obtained from the head of the sperm whale, *Physeter macrocephalus*.—U. S.

Cetaceum is official in nearly all pharmacopœias.

Origin.—The sperm whale, or great-headed cachalot, is principally met with in the Pacific and Indian oceans and the seas of Australia. It is 15 to 21 M. (50 to 70 Ft.) long, with a head fully one-third of its entire length and correspondingly thick. Anterior to the cranium the upper jaw has a large cavity containing an oily liquid, which is removed with buckets soon after the animal has been killed, and then congeals into a yellow mass. This is drained in suitable bags, and then strongly expressed to remove the oil; the pressed cake is purified by melting it in water, skimming off the impurities, boiling with weak potassa solution, and washing with water; it is finally allowed to congeal into the substance under consideration.

Description.—Spermaceti is in white, translucent, scaly-crystalline masses somewhat unctuous to the touch, of a slight fatty odor, a mild, bland taste, a laminated pearly fracture, and a neutral reaction. Its specific gravity is 0.943 at 15° C. (59° F.); 0.938–0.944 at 25° C. (77° F.) or 0.842 at 100° C. (212° F.).—U. S. It melts near 50° C. (122° F.) (between 50° and 54° C., P. G.) to a clear and nearly colorless liquid, which congeals at about 45° C. (113° F.). The U. S. P. gives the melting-point at between 45° and 50° C. (113° and 122° F.). It contains variable, but small quantities of oil, which causes spermaceti to become yellowish on exposure to air, and to acquire a rancid odor and acid reaction. It is insoluble in water and nearly so in cold alcohol, is slightly soluble in cold benzin and benzene, but dissolves in chloroform, ether, carbon disulphide, warm methyl and ethyl alcohol, about 50 parts of boiling alcohol (U. S.), and in fixed and volatile oils. An alcoholic solution of spermaceti is neutral to litmus-paper. On dry distillation an oily liquid, a solid fatty compound, and various gases and volatile acids are obtained. Spermaceti is readily inflammable, and burns with a bright, somewhat sooty flame.

Constituents.—When repeatedly recrystallized from boiling alcohol the fat is removed and Chevreul's *cetin* is obtained, which crystallizes in soft white pearly scales, melts between 50.5° and 53.5° C. (123° and 128.3° F.), and is slowly decomposed by aqueous solution of potassa, but readily saponified on fusion with potassium hydroxide or on boiling with its alcoholic solution. It consists mainly of cetyl palmitate, $C_{16}H_{33}.C_{16}H_{31}O_2$, which melts between 54.5° and 55° C. (130° and 131° F.), and yields on saponification palmitic acid and cetyl alcohol, or *ethal*, $C_{16}H_{34}O$. Heintz (1854) obtained also small quantities of myristic, lauric, and stearic acids, and of the alcohols methal, $C_{14}H_{30}O$, and

stethal, $C_{18}H_{38}O$. When boiled with nitric acid spermaceti is slowly oxidized, œnanthylic, succinic, and other acids being found among the products.

Spermaceti has been found adulterated with stearic acid, and the following test given in the U. S. P. serves to detect its presence: If 1 Gm. of spermaceti be boiled with 1 Gm. of anhydrous sodium carbonate and 50 Cc. of alcohol, and the mixture cooled and filtered, the filtrate, upon being supersaturated with acetic acid, may become turbid, but should not afford a precipitate.

Action and Uses.—Spermaceti is practically devoid of medicinal properties, but is employed as a lenitive and protective in early inflammations of mucous membranes. It is said to be useful in irritable conditions of the gastro-intestinal and genito-urinary tracts, and of some value in acute pharyngitis and bronchitis. 1 part of the drug finely powdered may be mixed with 3 parts of sugar and employed in this manner; or the drug may be dissolved in an equal amount of expressed oil of almond and emulsified with yolk of egg or acacia.

CETRARIA.—Cetraria.

Lichen Islandicus, P. A., P. G.—*Iceland moss*, E.; *Isländisches Moos, Isländische Flechte, Lungenmoos*, G.; *Lichen (Mousse) d'Islande*, Fr. Cod.; *Liquen islandico*, Sp.; *Muscayo Islandico, M. amargo, Licken*, Port.

The dried plant, *Cetraria Islandica* (L.) Acharius (*Lichen I.* L.; *Parmelia I.* Spreng.—Class *Lichenes*).

Cetraria is official in nearly all pharmacopœias, most of which provide for treating it with alkali carbonates to remove the bitterness. Several note that diluting the jelly with water, precipitating with alcohol, and treating the still moist precipitate with iodine, impart a blue color.

Origin.—The plant is indigenous to the northern hemisphere; in its southern limits it is found in mountainous regions, and further north in the plains. In North America it is met with southward to the mountains of North Carolina, northward throughout British America, and westward to the Rocky Mountains as far south as Colorado; in Europe it grows as far south as Spain and Italy, and in Asia throughout Siberia and in the Himalaya Mountains; it is plentiful in Iceland, from which island its name is derived.

Fig. 97.

Cetraria Islandica.

Description.—From 5 to 10 Cm. (2 to 4 In.) long and of very irregular breadth, thin and leaf-like, much and irregularly branched, the lobes about 5 Mm. (¼ In.) broad, channelled by the upcurving of the margins, shortly and finely fringed; brown or greenish-brown above; silvery-gray with depressed whitish spots underneath, forming an elastic mass, brittle when dry, cartilaginous when damp; almost inodorous when dry; bitter and somewhat mucilaginous. The 5 per cent. decoction becomes gelatinous when cold. The ash should not exceed 2 per cent.

Cetraria is very apt to contain vegetable forest débris in the form of pine-needles, twigs, leaves, etc.

Constituents.—This lichen depends for its nutritive value on the starchy principles, *lichenin* or *lichen-starch* ($C_{12}H_{20}O_{10}$) and *isolichenin* (lichenoid), which constitute together 30 to 70 per cent. of the drug, the lichenin predominating. The drug contains also 2 to 3 per cent. of cetrarin, which occurs in very bitter, white, odorless crystals, soluble in absolute alcohol and ether, and slightly in water. It has been split up into *cetraric acid* ($C_{18}H_{16}O_8$), intensely bitter and crystallizable; *lichen-stearic acid* ($C_{14}H_{34}O_3$); and *thallochlor*, a green coloring-matter. The other constituents are 3.6 per cent. of uncrystallizable sugar, 3.7 per cent. of gum, and fumaric (lichenic), tartaric, and oxalic acids.

Action and Uses.—Iceland moss is stated to possess tonic properties, but it is principally employed as a demulcent and nutrient. It aids digestion, improves nutrition, and increases the appetite. Cetraria has been used in chronic affections of mucous membranes, such as chronic bronchitis, tuberculosis with profuse expectoration, chronic diarrhœa, and dysentery. It has also been recommended in hæmoptysis, but in this condition is of doubtful efficiency. Its bitter principle, cetrarin, is said to increase peri-

stalsis, and may be used in chronic constipation. It may also be of benefit in the treatment of chlorosis.

Iceland moss is usually employed in the form of the decoction in doses of 1 fluidounce (30 Cc.), several times daily. Cetrarin has been given in doses of 1½ grains (0.075 Gm.). The dose of the drug in substance is from ½ to 1 drachm (2–4 Gm.).

GYROPHORA ESCULENTA Miyoshi is known as the edible lichen of Japan, where it grows on moist granite rocks, and is collected in great quantities, and used generally in Japanese cooking, more or less being also exported. It contains apparently nutritive constituents similar to those of Cetraria, but lacks the bitter principle and taste.

CHARTA POTASSII NITRATIS.—Paper of Potassium Nitrate.

Charta nitrata, P. G.—*Saltpeter paper*, E.; *Papier nitré*, Fr.; *Salpeterpapier*, G.; *Carta nitrata*, It.

Preparation.—Potassium nitrate, 200 Gm.; distilled water, 800 Cc. Dissolve the potassium nitrate in the distilled water. Immerse strips of white, unsized paper in the solution and dry them. Preserve the paper in securely closed vessels.—U. S.

If 4 avoirdupois ounces and 75 grains of potassium nitrate be dissolved in 1 pint of distilled water, the solution will be of the strength directed by the Pharmacopœia, which is very nearly saturated.

The German Pharmacopœia uses a somewhat weaker solution, 1 part of potassium nitrate to 5 parts of water.

Ordinary saltpeter will answer if the paper is to be used for moxas, but for the preparation of *medicated cigarettes* potassium nitrate free from chloride should be used, and the paper should also be free from chlorine compounds. Such cigarettes are made either in the same manner as ordinary cigars, except that stramonium, belladonna, hyoscyamus, or other leaves are substituted for tobacco, or the nitrated paper is impregnated with other solutions, or simply rolled into a thin tube having the edges fastened with a trace of gelatin; the substance whose smoke is to be inhaled is then introduced and the paper tube ignited at one end, when combustion without flame takes place. The following is a formula for *cigarettes antiasthmatiques* which is much employed in France: A decoction is made of 5 Gm. each of the leaves of belladonna, stramonium, digitalis, and sage, with 1000 Gm. of water, and strained. 75 Gm. of potassium nitrate and 40 Gm. of tincture of benzoin are added, and into this solution is then introduced, sheet by sheet, one quire of red-tinted absorbent paper, the whole remaining in contact for 24 hours; after which time the paper is dried and cut into rectangular pieces of 10 by 7 Cm., which are formed into tubes by rolling them around a cylinder about 1 or 1½ Mm. in diameter and fastening the edge with gelatin.

For forming *moxas* of nitrated paper, it is rolled into pretty firm cylinders having a diameter of about ¼ inch, which are afterward cut into pieces of suitable length.

Medical Uses.—Papers of potassium nitrate are intended to be burned in front of the patient, who inhales the fumes. They are considered an efficient remedy in the treatment of asthma.

CHARTA SINAPIS, *U. S.*, *Br.*—Mustard Paper.

Charta sinapisata, P. G.; *Papier moutarde*, *Moutarde en feuilles*, Fr.; *Senfpapier*, G.; *Charta senapata*, It.

Preparation.—Black mustard, in No. 60 powder, 100 Gm.; rubber, 10 Gm.; benzin, carbon disulphide, each a sufficient quantity. Pack the mustard in a conical percolator, and gradually pour petroleum benzin upon it until the percolate ceases to produce a permanent greasy stain upon blotting-paper. Remove the powder from the percolator and dry it by exposure to the air. Having meanwhile dissolved the rubber in a mixture of 100 Cc. each of petroleum benzin and carbon disulphide, mix the purified mustard with a sufficient quantity of the solution to produce a semiliquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather stiff, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of 60 square Cm. should contain about 4 Gm. of black mustard deprived of oil. Before it is applied to the skin, mustard-paper should be dipped in warm water for about 15 seconds.—U. S.

The British Pharmacopœia directs the removal of the fixed oil from a mixture of equal proportions of black and white mustard seeds by percolation with benzene. The residue is dried by exposure to warm air and reduced to No. 60 powder, of which 5 Gm. are mixed with 18 Cc. of solution of India-rubber and spread over 20 square Cm. of one side of a piece of cartridge-paper. It is allowed to dry by exposure to air. This preparation contains nearly 4 times as much mustard to the square inch as that of the U. S. P.

The German Pharmacopœia directs that 100 square Cm. (about 16 square inches) of mustard paper shall yield at least 0.0236 Gm. (nearly 0.5 grain) of volatile oil of mustard, and gives a method for determining the value which involves conversion of the volatile oil obtained into thiosinamine by means of ammonia.

Action and Uses.—Mustard papers should be immersed in lukewarm water for an instant before being applied to the skin. They are more convenient and more cleanly than the ordinary mustard poultice, and are employed for the same purposes. When it is desirable to modify the action of these papers, a piece of thin gauze may be placed between them and the skin. This also prevents particles of mustard from adhering to the skin after removal of the paper. As a rule they should not be allowed to remain longer than 15 minutes.

CHELIDONIUM.—Chelidonium.

Herba chelidonii.—*Garden or Great celandine, Tetterwort, Wart-weed, Cock-foot,* E.; *Schöllkraut,* G.; *Chélidoine, Herbe à l'hirondelle,* Fr.; *Celidonia mayor,* Sp., Port.; *Herva Andorinha,* Port.

The dried plant, *Chelidonium majus* L. (*C. umbelliferum* Stokes.—Fam. *Papaveraceæ*).

Chelidonium is official in several pharmacopœias.

Origin.—This perennial, yellow-juiced herb, described below, the only species of its genus, is native of Europe, and commonly naturalized in waste places in the United States.

Fig. 98.

Chelidonium; small upper leaf, flower, and fruit (¾ Nat.).

Fig. 99.

Chelidonium: root (Nat.).

Description.—Root several-headed, elongated, branching, reddish-brown; stem 30 to 60 Cm. (1 to 2 Ft.) long, loosely and widely branched, hairy, green; leaves 10 to 20 Cm. (4 to 8 In.) long, petioled, glaucous underneath, lyrate-pinnatifid, the pinnæ ovate-oval, obtuse, coarsely crenate or incised; flowers pedicelled in loosely peduncled umbels, yellow, of 2 sepals, 4 petals, indefinite stamens and a lance-linear pistil with entire stigma; capsule linear, 2-celled, completely dehiscent, many-seeded; odor narcotic, disagreeable; taste very acrid.

Constituents.—The active principles consist of chelidonine, chelerythrine, protopine (as in opium and sanguinaria), alpha- and beta-homochelidonine ($C_{21}H_{21}NO_5$), and chelidoxanthin. *Chelidonine* ($C_{19}H_{17}N_3O_3$ or $C_{20}H_{19}NO_5$), identical with stylophorine, occurs in bitter, afterward acrid, colorless, shining plates, insoluble in water, and soluble in chloroform, volatile and fatty oils, and scarcely soluble in alcohol. *Chelerythrine* (pyrrhopine, methyl-sanguinarine, $C_{21}H_{17}NO_4$) forms bitter, fluorescent, optically inactive needles, soluble in alcohol, ether, chloroform, and oils, but not in water. Orlorr found it in all parts of the fresh plant, but none in the dried, 0.001 to 0.005 per cent. in the fresh root, and 0.06 per cent. in the fruit. *Chelidoxanthin* is a neutral bitter principle, crystallizing in yellow needles. Orlorr found 0.005 to 0.01 per cent. when the plant was in bloom, but none in the early spring. He believed it to be an alkaloid. The acids are a succinic acid derivative, malic, and chelidonic ($C_7H_4O_6$), which crystallizes in colorless silky needles and is soluble in water and alcohol. The other constituents are gum, extractive, chlorophyll, etc.

Action and Uses.—Chelidonine closely resembles morphine in its effect upon the central nervous system. It is a violent purgative, and in overdose acts as a powerful local irritant with a special narcotic action upon the central nervous system. The yellow juice of the fresh plant was formerly employed in the treatment of catarrhal jaundice, ascites, and intermittent fever, and at present meets with favor among some practitioners. Because of its irritant action upon the skin, it has been used to a limited extent in the treatment of certain chronic cutaneous affections, especially those attended with severe itching. The juice is also a popular remedy for the removal of warts.

An infusion made with 1 ounce (30 Gm.) of the drug to 1 pint (480 Cc.) of boiling water is given in the dose of from ½ to 1 fluidounce (15–30 Cc.). The dose of the drug in substance is from ½ to 2 drachms (2–8 Gm.), ; of the extract, from 5 to 15 grains (0.30–1 Gm.).

Allied Drugs.—Several related and similar drugs are considered under PAPAVERACEÆ. Under the name *Wild eclandine* (*Wild balsam* or *Wild ladies' slipper, Jewel-weed, Silver-weed, Slipper-weed, Touch-me-not, Quick-in-the-hand, Snap-weed*), the herbage of *Impatiens aurea* Muhl. (*I. pallida* Nutt.), the pale *Touch-me-not*, etc., and of *I. biflora* Walt. (*I. fulva* Nutt.), the *Spotted touch-me-not*, etc. (Fam. *Balsaminaceæ*), of eastern and central North America, are largely employed in domestic practice and by homœopaths and eclectics. The plants are tall and branching, but tender and delicate succulent annuals, with swollen joints, growing beside streams and in similar damp localities. They are smooth and somewhat glaucous, the stem somewhat translucent, the foliage showing a brilliant silvery surface when immersed in water, which will not adhere to the surface. The leaves are thin, ovate-oval, more or less toothed. The slipper-shaped yellow flowers have long recurved tails, those of the first-named species being of a uniform pale-yellow, those of the second orange-yellow and spotted. The oblong capsules, when ripe, explode upon the slightest disturbance, scattering the seeds widely. The chemical constituents are not known, though the leaves apparently contain tannin. The medicinal applications are wholly questionable, except that the fresh juice appears to relieve cutaneous irritation of various kinds, especially that due to rhus-poisoning.

CHENOPODIACEÆ.—The Spinach Family.

Genera about 75, species about 600, contributing many troublesome weeds, as well as the drug CHENOPODIUM (which see), and the highly important food-plants, beet, spinach, and quinoa. These plants, besides their nitrogenous value, are noted for their large content of iron in the form of digestible organic compounds. The *Beet*, *Beta vulgaris* L. (*B. maritima* L.—*Runkelrübe, Zuckerrübe*, G.; *Bettarave*, Fr.), is a native of southern Europe and is most extensively cultivated, especially for the production of cane-sugar (see SACCHARUM), and presents many varieties. Its juice is considerably used for the production of coloring-matter for wine. This is sometimes used also as a substitute for litmus. The tops are an excellent substitute for spinach. The *Spinach*, *Spinacea oleracea* L. (*Epinard*, Fr. ; *Espinacea*, Sp.), is a native of northern Asia, and is well known in cultivation. The *Shammum* of Asia is very similar. An excellent substitute for spinach is the young tops of the common garden-weed, *Chenopodium album* L. (*Lamb's-quarters* or *Pigweed*). The seeds of *C. Quiona* W. (*Quinoa* or *Quinua*, *Pettyrice*), of the Andean region, there constitute the staple and principal food of millions of people. They contain also an amaroid, in specially large amounts in the bitter variety, which is reputed anthelmintic and emetic. By repeated washings, the substance is removed, and the seeds used as a food like the sweet variety.

CHENOPODIUM.—Chenopodium.

Fructus chenopodii anthelmintici.—American worm-seed, Mexican, Spanish, Jerusalem, or Jesuit tea, Jerusalem oak, E.; *Amerikanischer Wurmsamen, Wohlriechender Gänsefuss, Mexicanisches Traubenkraut,* G.; *Ambrosie du Mexique,* Fr.; *Anserine vermifuge (plante fleurie),* Fr. Cod.; *Epazote, Te de Espāna,* Sp.

The dried ripe fruit of *Chenopodium ambrosioides* L. or of *C. anthelminticum* L. (*C. Ambrosioides anthelminticum* Gray.—Fam. *Chenopodiaceæ*).

Chenopodium is official in most pharmacopœias.

Origin.—Viscid-glandular, rankly and offensively smelling, perennial herbs, the former native of tropical America, the latter of Europe, both widely naturalized and growing abundantly in America, especially in the eastern United States, as coarse weeds of the roadside and waste places.

Fig. 100.

Chenopodium ambrosioides (¾ Nat.).

Description.—Nearly 2 Mm. ($\frac{1}{15}$ In.) broad, depressed globular, brown or greenish-brown, the pericarp membranaceous and friable, inflated, the single seed black and shining, lenticular through its spiral curvature; aromatic, somewhat terebinthinate; taste bitterish, pungent.

Constituents.—Its medicinal importance is due to the volatile oil (see Oleum Chenopodii). Betaine and choline have also been reported. The fresh plant yields the alkaloid *chenopodine*, $C_6H_{13}O_4$, a white tasteless and odorless crystalline powder, soluble in 11 parts of cold water, 3 of boiling water, and 202 of alcohol.

Action and Uses.—Chenopodium is a very active anthelmintic, and is frequently employed for the expulsion of lumbricoid worms, especially in children. The bruised fruit may be given in doses of 20 grains (1.3 Gm.), in the form of an electuary. The expressed juice of the fresh plant is also employed in tablespoonful (16 Cc.) doses. A decoction made by boiling 1 ounce (30 Gm.) of the fresh plant with 1 pint (480 Cc.) of milk or water, is sometimes given in doses of a wineglassful (60 Cc.). The dose of the volatile oil is from 5 to 10 minims (0.3–0.6 Cc.). When employed, the drug should be given 3 times daily for a period of 3 or 4 days, and then be followed by calomel or castor oil.

Other Species.—Of the 60 or more widely distributed species, several of tropical America belong to the same section with the official, and share its peculiar odor and doubtless its properties, but are not commercial articles, with the exception of *C. Botrys* L., the *Mexican tea, Jerusalem oak, Feather geranium, Traubenkrant* or *Chenopode à grappes. C. vulvaria* L., the *Fetid* or *Stinking goosefoot, Notchweed, Stinkender Meede, Vulvaire, Ansérine puante,* has also a fetid odor, though somewhat different from that of Chenopodium, and is used as an antispasmodic. Other species possess very different properties and are considered under Chenopodiaceæ.

CHIMAPHILA, *U. S.*—Chimaphila.

Pipsissewa, Prince's pine, Bitter wintergreen, Ground holly, King's cure, Love in winter, E.; *Doldenblüthiges Harnkraut, Wintergrün,* G.; *Herbe de pyrole ombellée,* Fr.

The dried leaves of *Chimaphila umbellata* (L.) Nutt. (*Pyrola u.* L.—Fam. *Ericaceæ*).

Chimaphila is not official in any other pharmacopœia.

Origin.—An herb-like undershrub, a few inches long, bearing several leaves crowded near the summit, and an umbel of 5 or 6 wax-like flowers, nearly a half-inch broad, having 5 petals, 10 stamens with the filaments enlarged in the middle and the anthers conspicuously 2-horned, a short style, with the disk-like and 5-lobed stigma nearly immersed in the top of the ovary, and a 5-celled and many-seeded capsule. It is indigenous in North America, northern Asia, and northern and central Europe, growing in dry woods and flowering in June and July.

Description.—From 2.5 to 5 Cm. (1 to 2 In.) long and 1 to 1.5 Cm. ($\frac{2}{5}$ to $\frac{3}{5}$ In.) broad, oblanceolate, the lower half cuneate and entire, the upper coarsely and sharply serrate, acute or obtusish, thick and rigid, brittle, above dark-green or brownish-green, and slightly shining, the veins strongly impressed, underneath paler, the veins very prominent; odor very slight, tea-like; taste astringent and bitterish.

The leaves of *C. maculata* (L.) Pursh (*Pyrola m.* L.) the *Spotted pipsissewa*, *S. Wintergreen* or *S. piperidge*, of the eastern United States, is used similarly, and is sometimes substituted for it, but the leaves are lanceolate and pointed, and have a large whitish spot or blotch on the upper surface.

Constituents.—Chimaphila yields odorless, tasteless, golden-yellow needles of *chimaphilin* ($C_{24}H_{21}O_4$), *arbutin* ($C_{12}H_{15}O_7$, see Uva Ursi), another body ($C_{10}H_{19}O$), 3 other crystalline principles, and 4 or 5 per cent. of tannic acid; also volatile oil, fat, resin, starch, and gum.

Pharmaceutical Preparation.—Fluidextract of Chimaphila, U. S. P.

Action and Uses.—Chimaphila is slightly astringent, and has been employed as a tonic and diuretic. It is a stimulant to the mucous membranes of the genito-urinary tract, and may be employed in any depraved condition arising therein. It has been especially recommended in renal dropsy, and is said to be of service in scrofulous conditions and in chronic ulcers and skin lesions presumably the result of a strumous diathesis. It is employed both internally and as an embrocation.

The drug is administered in the dose of from 1 to 2 drachms (4–8 Cc.), of the fluidextract, 3 times daily.

Fig. 101.

Chimaphila (Nat.).

CHINOIDINUM.—Chinoidine.

Chinioidinum, *Chinoidina*, *Quinoidina.*—*Quinoidine*, E., Fr.; *Amorphous quinine*, E.; *Quinine amorphe*, Fr.; *Chinoidin*, G.

Chinoidine is a resinous substance consisting of the natural or artificial (obtained by the action of heat and acids upon the crystalline alkaloids) *amorphous* alkaloids of cinchona bark.

Preparation.—The mother-liquor obtained in the preparation of quinine, cinchonine, etc., from cinchona bark, and freed as much as possible from the crystallizable alkaloids, is precipitated with sodium hydroxide, and the precipitated chinoidine purified by dissolving it in dilute hydrochloric acid, precipitating by ammonia, washing with water, and drying.

The alkaloidal nature of chinoidine was first observed by Sertürner. Subsequently, Henry and Delondre, Duflos, Winckler, and others showed that this amorphous mass still contained quinidine (then confounded with quinine) and cinchonine. Freed from the crystallizable alkaloids, Liebig regarded chinoidine as quinine rendered amorphous by the influence of heat and of chemicals. Hesse (1877) has shown that aside from the crystallizable bases which may be present, chinoidine has been formed by the condensation or polymerization of their molecules.

The two principal amorphous alkaloids present are *diconchinine*, $C_{40}H_{46}N_4O_3$, and *dicinchonine*, $C_{38}H_{44}N_4O_2$, the former being the principal constituent of chinoidine when the cinchona bark contains much quinine and quinidine, resembling these two alkaloids in the fluorescence of the sulphuric acid solution and in the thalleioquin reaction. Much *dicinchonine* is present if the bark contained much cinchonine and cinchonidine.

Properties.—Chinoidine is met with in commerce in cylindrical rolls or in deep-brown to brownish-black masses of a resin-like appearance, which at low temperatures are brittle and break with a glossy conchoidal fracture. Exposed to summer heat, it becomes plastic, readily melting when heated to higher degrees, and when ignited burns with a sooty flame. Chinoidine has a feebly bitter taste, is almost insoluble in water, becomes plastic in hot water, soluble in water acidulated with mineral acids, soluble in alcohol and chloroform, the solutions reacting alkaline and tasting very bitter, and are dextrorotatory. Chinoidine gives the thalleioquin reaction as well as the red color when chlorine water, potassium ferrocyanide, and ammonia are added successively as in the test for quinine.

Tests.—1 Gm. dissolved in 10 Cc. of 3 per cent. acetic acid, or in 10 Cc. of diluted alcohol (49 per cent. by volume), should give a clear solution, or when ignited and burned should not leave more than 0.6 per cent. of ash (Hager).

Pharmaceutical Preparations.—Tinctura Chinoidini. *Tincture of Chinoidine*, E.; *Chinoidintinktur*, G.—Dissolve 10 parts of chinoidine in a mixture of 85 parts of alcohol specific gravity 0.894 and 5 parts of hydrochloric acid. It is dark-brown, transparent in thin layers, very bitter, and without distinctive odor; on mixing it with an equal volume of water and of ammonia the chinoidine is precipitated and the liquid becomes yellowish.—P. G. 1882.

Action and Uses.—Chinoidine is tonic and antiseptic. It has been recommended in the treatment of intermittent fever, and also of chronic malarial conditions attended with cachexia. Small doses may also be administered for its tonic effect during convalescence from acute disease. The drug is slower in its action and less powerful than the cinchona alkaloids, and ordinarily is much inferior to them, but it may be employed in those cases in which idiosyncrasy prevents the use of quinine. The dose to an adult is stated to be from 10 to 20 grains (0.60–1.3 Gm.), but as much as 1 drachm (4 Gm.) has been given. To a child the beginning dose is 2 or 3 grains (0.12–0.20 Gm.). Care should be taken in its employment, because of its liability to produce gastric disturbances.

COMPOUNDS OF CHINOIDINE.

Chinoidini Citras. *Chinoidine citrate*, E.; *Chinoidincitrat*, G.—Prepared by saturating a 15 per cent. aqueous solution of citric acid with chinoidine at a gentle heat, and evaporating the solution to dryness. Transparent reddish-brown scales soluble in water.

Chinoidine Hydrochloride, Chinoidine Acetate, and **Chinoidine Sulphate** may be prepared in a similar manner with the respective acids.

Chinoidini Tannas. *Chinoidine tannate*, E.; *Gerbsaures Chinoidin*, G.—Prepared by dissolving 10 parts of chinoidine in 500 Cc. of water containing 7.5 parts of hydrochloric acid (25 per cent.) and precipitating this with a solution of 40 parts of tannic acid in 400 Cc. of water, and then adding a solution of 20 parts of crystallized sodium acetate in 200 parts of water, which causes an additional precipitate. The precipitate is collected, thoroughly washed, and then dried over dehydrating agents. An amorphous brownish-colored powder having a bitter and astringent taste, difficultly soluble in water and alcohol, but soluble in acidulated water or alcohol.

CHIRATA, *U. S., Br.*—Chirata.

East Indian balmony, E.; *Chiretta*, E., G.; *Ostindischer Enzian*, G.; *Chirette*, Fr.; *Chirayta*, Port.

The dried plant, *Swertia Chirayita* (Roxb.) Ham. (*Swertia C.* Ham.; *Ophelia C.* Griseb.; *Agathotes C.* Don.—Fam. *Gentianaceæ*).

Origin.—A large annual of the Himalaya mountains.

Description.—Smooth; stem yellowish- or purplish-brown, about 1 M. (3 Ft.) long, slender, cylindrical below, above quadrangular and lightly winged, with numerous slender, opposite, ascending branches, the woody zone narrow, the pith large, yellowish-white, continuous, easily detached; leaves opposite, sessile, ovate, acute, entire, 5-nerved; flowers small, 4-merous; capsule ovoid, acute, 2-carpelled, 1-celled, many-seeded; nearly inodorous, very bitter.

Adulterants and Substitutes.—Several species of *Swertia* (subgenus *Ophelia*), *Exacum*, and allied genera, are known in India as Chirata, and are distinguished from the official drug as *puharee* (hill), *dukhunee* (southern), *ooda* (purple), and *meetha* (sweet) chirata; they appear to be indiscriminately collected and sent to Bombay, where, according to Dymock, the drug is garbled. From all these, the official species is to be distinguished in the entire condition by its large and continuous pith, its yellowish or brownish stem, and its greater bitterness. In the powdered state they would be difficult, even if possible, of detection. *Erythæa Roxburghii* has also been detected. It is but a few inches in height. Madder (which see) has sometimes been used as an adulterant. Perhaps the most noteworthy substitute has been the herb *Andrographis paniculata* Nees (Fam. *Acanthaceæ*). It is readily distinguished, the stems being strongly quadrangular and furrowed, the leaves

Fig. 102.

Gland from Andrographis (enlarged).

elongated and narrow, and the corolla 2-lipped. The powder is equally well characterized by numerous cystoliths, pith-cells containing crystals of calcium oxalate, and stalked glands (Fig. 105) from stems and leaves.

Constituents.—This plant yields a very little tannin, wax, and 2 bitter principles, *ophelic acid* ($C_{13}H_{20}O_{10}$) and *chiratin* or *chirettin* ($C_{26}H_{48}O_{15}$). Ophelic acid forms a brown, very hygroscopic, amorphous mass which is readily soluble in water, alcohol, and ether, has a slightly acidulous, afterward intensely bitter taste, precipitates cuprous oxide from Trommer's Solution, and produces yellow precipitates with the lead acetates. Chiratin is bitter, pale-yellow, indistinctly crystalline, soluble in ether, and precipitated by tannin. Dilute acids split chiratin into ophelic acid and *chiratogenin* ($C_{13}H_{24}O_3$), a brown, amorphous, bitter substance, soluble in alcohol but nearly insoluble in water.

Pharmaceutical Preparations.—Fluidextract of Chirata, U. S. P.; Infusion of Chirata, Br. P.; Tincture of Chirata, U. S. P.

Action and Uses.—Chirata is a tonic and hepatic stimulant, and may be prescribed in cases of impaired digestion, especially when hepatic torpor or constipation is present. Its properties are practically the same as those of gentian and calumbo, and it may be prescribed interchangeably with them. In Hindostan it is highly esteemed as an antispasmodic and deobstruent, and is said to be a valuable remedy in chronic bronchitis and in the depression during convalescence from acute infectious diseases. The dose of the powdered drug is 20 grains (1.3 Gm.); of the tincture, from 1 to 4 fluidrachms (4–16 Cc.); of the extract, from 3 to 4 grains (0.20–0.25 Gm.); and of the infusion, a wineglassful several times daily.

CHLORALFORMAMIDUM, *U. S.*—Chloralformamide.

Chloralum formamidatum, P. G.—*Chloralamide*, E.; *Chloralformamid*, G.

Formula, $CCl_3CH(OH)NH.(HCO)$. Molecular weight, 190.96.

A crystalline solid made by the direct union of formamide and anhydrous chloral. It should be kept in amber-colored, well-stoppered vials.—U. S.

Preparation.—147 parts of anhydrous chloral (CCl_3CHO) and 45 parts of formamide ($CHONH_2$) are intimately mixed at ordinary temperatures and the mass allowed to crystallize, after which it is purified by recrystallizing from water or 30 per cent. alcohol, care being taken not to heat it above 60° C. (140° F.).

Properties and Tests.—Chloralformamide occurs as colorless, lustrous crystals, without odor, and having a somewhat bitter taste. It is soluble in about 18.7 parts of water and in 1.3 parts of alcohol at 25° C. (77° F.), and is readily soluble in glycerin, ether, acetone, and acetic ether. When heated to 60° C. (140° F.) with water, it is decomposed into its component parts, chloral and formamide. When heated to 114°–115° C. (237.2°–239° F.) it melts, but at a higher temperature is decomposed. It is not affected by diluted acids, but is decomposed on warming with alkali hydroxides, the solution becoming at first turbid, and then clear, while chloroform separates. If 0.2 Gm. be heated carefully in an open dish, it should not give off inflammable vapors, and should volatilize without leaving a weighable residue (absence of inorganic impurities and distinction from chloral alcoholate and ethyl carbamate). 1 Gm. of chloralformamide dissolved in 10 Cc. of alcohol should yield a solution which does not redden blue litmus-paper (absence of formic, hydrochloric, or other free acids). If 1 Gm. of chloralformamide be dissolved in 10 Cc. of alcohol, the addition of a few drops of silver nitrate test-solution should not at once produce turbidity (absence of decomposition-products).—U. S. The description and tests of the German Pharmacopœia are identical with the above, except that the solubility is stated to be 1 part in 20 parts of water and in 1.5 parts of alcohol at 15° C. (59° F.).

Chloralformamide dissolves in water slowly at the ordinary temperature, and a moderate heat may be employed to hasten solution, but care should be taken not to exceed a temperature of 55° C. (131° F.), since decomposition occurs at 60° C. (140° F.), as stated above.

The name *chloralamide*, under which this compound was first introduced, is a misnomer, but is still used commercially (see Chloral-ammonium). It is easily confounded with *chloralimide*, CCl_3CHNH, a product obtained by the action of heat on chloral-ammonium, which is insoluble in water.

Action and Uses.—Chloralformamide is purely a hypnotic, and may be employed for the relief of hysteria and insomnia which is not accompanied by pain. It is somewhat slower and less certain in its action than is chloral, but its effect resembles that of the latter remedy. It has practically no effect upon the circulation, and for this reason is considered a safer remedy than chloral if cardiac lesions are present. Its effect upon the spinal cord and nerves is not marked, but upon the intellectual centers of the brain it acts as a powerful depressant, producing sleep in from 15 to 30 minutes, which lasts for 6 to 8 hours. It rarely causes disagreeable after-effects, but occasionally headache, vertigo, and delirium have followed its administration. The drug is rapidly absorbed from the stomach and intestines, and is eliminated by the kidneys as urochloralic acid. Poisonous doses are said to depress the heart muscle, the motor side of the cord, motor nerve-trunks, and muscles. The ordinary dose of chloralformamide is from 20 to 40 grains (1.3–2.6 Gm.), but as much as 1 drachm (4 Gm.) may occasionally be required. It may be given in capsules, in aqueous or in alcoholic solutions.

CHLORALUM HYDRATUM, *U. S.*, *P. G.*—Hydrated Chloral.

Chloral hydras, Br.; *Chloral*, U. S., 1890; *Aldehydum trichloratum.*—*Chloral hydrate, Hydrous chloral, Trichloraldehydehydrate, Trichlorethylidene glycol*, E.; *Hydrate de chloral*, Fr.; *Chloralhydrat*, G.; *Cloralio idrato*, It.; *Cloral hidratado*, Sp.

Formula, $C_2HCl_3O + H_2O$ or $CCl_3.COH + H_2O$. Molecular weight, 164.12.

A crystalline solid, composed of trichloraldehyde or chloral with 1 molecule of water.—U. S.

Chloral hydrate, or trichlorethylidene glycol, $CCl_3.CH(OH)_2$, is obtained by the addition of water to the liquid chloral produced by the action of dry chlorine gas on ethyl alcohol.—Br.

It should be kept in glass-stoppered bottles, in a cool and dry place.

Chloral was discovered by Liebig (1832), and its composition soon after determined by him and Dumas. Its hypnotic properties were discovered by Dr. O. Liebreich, Berlin (1869), and within 10 years its consumption as a remedial agent increased to about a ton per day in England and America alone.

Preparation.—Chloral (anhydrous) is first prepared by conducting a current of dry chlorine gas into cooled absolute alcohol until hydrochloric acid gas ceases to distil. At this stage the temperature is gradually increased to near 100° C. (212° F.), and the current of chlorine continued until the crude chloral dissolves quite clear in water. The liquid which congeals on cooling is thoroughly washed with concentrated sulphuric acid to decompose chloral alcoholate and remove alcohol and other impurities, and the colorless oily layer which separates is then removed and rectified either direct or over lime and calcium carbonate. The final rectified distillate, *anhydrous chloral*, C_2Cl_3HO, is mixed with water (82 parts of chloral requiring 10 parts of water), and the mixture, which has become warm through the chemical reaction, is poured upon plates, covered with a bell glass, and allowed to crystallize, forming hydrated chloral or chloral hydrate, $C_2HCl_3O.H_2O$. For further purification the crystals are dissolved in benzin or chloroform and recrystallized.

According to the quantity of alcohol operated upon, the current of chlorine may require several days or weeks to complete the reactions (for 600 Gm. of alcohol 3 days, Dumas; for 92 pounds of alcohol 28 days, Dr. Squibb). Although the reactions in the formation of chloral, C_2HCl_3O, may be summarized in the substitution of 3 atoms of Cl for 3 atoms of H in aldehyde, C_2H_4O, the researches of Liebig, Dumas, Lieben, Trillat, and others indicate a series of very complicated interreactions between the products formed at various stages of the process, in which the following compounds have been shown to occur at different stages: Aldehyde, C_2H_4O; acetal (ethylidene-diethyl-ether), $CH_3.CH(OC_2H_5)_2$; trichloracetal, $CCl_3.CH(OC_2H_5)_2$; ethyl chloride, C_2H_5Cl; chloral alcoholate, $CCl_3.CHOH.OC_2H_5$; and the latter on the addition of concentrated sulphuric acid decomposing into chloral and ethyl sulphuric acid according to $CCl_3.CHOH.OC_2H_5 + H_2SO_4 = C_2HCl_3O + C_2H_5HSO_4 + H_2O$. Butyl-chloral, $C_4H_5Cl_3O$, and the chlorides of ethylene, $CH_2Cl.CH_2Cl$, and ethylidene, $CH_3.CHCl_2$, have been found as by-products in the manufacture of chloral.

Properties.—*Anhydrous chloral* is a colorless thin oily *liquid* of a peculiar pungent, irritating odor and caustic taste, having a density of 1.502 at 18° C. (64.4° F.), 1.544

at 0° C. (32° F.), boils at 94.5° C. (202° F.) and distils unchanged, and is easily soluble in ether and chloroform. It has a great affinity for water, alcohol, ammonia, and formaldehyde, the combinations resulting respectively in the formation of hydrated chloral, chloral alcoholate, chloral ammonium, $CCl_3CH.(NH_2)OH$, and chloralformamide, $CCl_3.CHOH.NH(HCO)$. On long keeping, chloral (anhydrous) is gradually polymerized, or more rapidly in contact with concentrated sulphuric acid, into *parachloral* (*metachloral*, *trichloral*), $C_6H_3Cl_9O_3$, which is a hard white substance insoluble in water, ether, and alcohol, but which may be reconverted into chloral by distillation at 180° C. (356° F.). The change into the insoluble variety is prevented by the addition of a little chloroform.

Hydrated chloral occurs in white crystalline masses or in separate colorless, oblique-rhombic crystals of a saccharoid aspect, having a peculiar aromatic and somewhat irritating odor, the pungency of which is increased with the temperature, and a bitterish, caustic taste; slowly volatile when exposed to the air; ordinarily not deliquescent, but much so if the water of hydration is excessive. If underhydrated, it is inclined to polymerize to the insoluble form, a phenomenon which may take place with explosive violence under suitable conditions. At 58° C. (136° F.), U. S., P. G., hydrated chloral fuses to a clear colorless liquid having the specific gravity 1.575, and congeals again to a crystalline mass between 35° and 50° C. (95°–122° F.) (48.9° C. (120° F.), Br.), the congealing-point being an indicator of the degree of hydration, a low congealing-point indicating overhydration and a high congealing-point—over 50° C. (122° F.)—underhydration.

At about 78° C. (172° F.) hydrated chloral begins to yield vapors of water and anhydrous chloral, boils at 97.5° C. (207.5° F.), and evaporates without residue. It is neutral in reaction to litmus, and freely soluble in water, alcohol, or ether; also in chloroform, benzene, petroleum benzin, carbon disulphide, fixed and volatile oils (U. S.). Soluble in 1½ parts of water (Allen); in less than its own weight of water, 90 per cent. alcohol or ether, and in 4 parts of chloroform (Br.); slowly in 5 parts of chloroform (P. G.). A freshly prepared aqueous solution of hydrated chloral should be neutral to litmus-paper, but it gradually acquires an acid reaction. A neutral alcoholic solution remains neutral permanently. In aqueous solution it is a solvent of morphine and quinine. Hydrated chloral liquefies when triturated with about an equal weight of camphor, menthol, thymol, or phenol. When warmed with a small quantity of aniline and sodium hydroxide solution an intensely disagreeable, mercaptan-like odor of phenyl-isocyanide (isonitril reaction) should be produced. Alkali carbonates slowly and alkali hydroxides rapidly decompose hydrated chloral into chloroform (of forensic importance) and alkali formates, the reaction proceeding with quantitative accuracy according to the equation $C_2HCl_3.H_2O$ (hydrated chloral) + KOH (potassium hydroxide) = $CHCl_3$ (chloroform) + $KCHO_2$ (potassium formate) + H_2O. In concentrated solutions it is oxidized by potassium permanganate to *trichloracetic acid*, $HC_2Cl_3O_2$, and in the system converted to *trichlorethyl alcohol*, $CCl_3.CH_2OH$ (Mering). It reduces Fehling's Solution, as well as solution of silver nitrate after the addition of ammonia. It gives a reddish-brown precipitate with solution of ammonium sulphide, and forms a sulphydrate with hydrogen sulphide. If hydrated chloral has acquired an acid reaction, it should be purified by washing with concentrated sulphuric acid and recrystallization from benzin or carbon disulphide.

Tests.—Hydrated chloral should be dry and not readily attract moisture. An aqueous solution of hydrated chloral (1 in 20), acidulated with nitric acid, should remain unaffected by silver nitrate test-solution (absence of hydrochloric acid and chlorides). If 1 Gm. of hydrated chloral be placed in a porcelain dish and be covered with 1 Cc. of nitric acid (specific gravity 1.38) no yellowish coloration of the mixture should be produced at ordinary temperatures, or even after warming the mixture 3 or 4 minutes, nor should yellowish fumes be produced after 10 minutes' warming (absence of chloral alcoholate).—U. S. 5 per cent. alcoholate reacts immediately after warming, and 1 per cent. after 3 to 4 minutes' heating (E. Hirschsohn). If 1 Gm. be dissolved in 6 Cc. of warm distilled water, and 0.5 Cc. of solution of potassium hydroxide added, the mixture filtered clear through wet filter-paper, and the filtrate treated with test-solution of iodine until it is deep brown, no yellow crystalline precipitate (iodoform) should appear even after standing 1 hour (absence of chloral alcoholate).—Br.

Chloral or hydrated chloral may be assayed quantitatively by conversion into *chloro-*

form by means of alkali hydroxide (see above), or by estimating the formic acid produced. 20.65 Gm. decomposed with strong solution of potassium hydroxide will yield 10 Cc. of chloroform specific gravity 1.491 measured at 17° C. (62.6° F.). A correction of 0.3 Cc. should be made for every 100 Cc. of aqueous liquid. 1 part of chloral hydrate yields 0.7218 part of chloroform by weight. The volumetric method of M. Meyer is convenient and accurate. About 2 Gm. of the sample are dissolved in water and shaken with calcium carbonate to remove free acid, filtered, and the filtrate mixed with a moderate excess of normal sodium hydroxide solution and the mixture shaken and set aside to allow the reaction to proceed to completion. The excess of alkali is then titrated with normal acid, using litmus as an indicator, each Cc. of normal alkali neutralized by the sample corresponds to 0.16497 Gm. of chloral hydrate. The Br. summarizes the test into "If 4 Gm. of chloral hydrate be heated with 30 Cc. of the volumetric solution of sodium hydroxide, not more than 6 Cc. of the volumetric solution of sulphuric acid should be required to neutralize the soda which remains free on the completion of the reaction." Care should be taken not to overheat the solution. It is better to simply mix them and set the mixture aside after a thorough shaking to complete the reaction.

Pharmaceutical Preparations.—Chloral and Camphor, N. F.; Compound Mixture of Chloral and Potassium Bromide, N. F.

Action and Uses.—Applied in its pure state to the sound skin, hydrated chloral produces redness, but upon the broken skin it acts as a powerful irritant. It is also a distinct irritant to mucous membranes when in concentrated form, a fact which should be remembered when administering it by either the mouth or the bowel.

Taken internally, hydrated chloral acts as a pure hypnotic. It does not produce sleep in cases suffering from severe pain unless the dose is so large as to be unsafe, but the sleep produced by it is as nearly normal as the sleep produced by any drug. The respiration and the circulation are somewhat slowed and the temperature is slightly lowered by medicinal amounts. The pupils are usually contracted. If full doses are given, or the patient is unduly susceptible to it, there may be some congestion of the conjunctiva and swelling of the eyelids. Curiously enough, with due regard to their weight, children can be given larger doses of hydrated chloral proportionately than adults. When sufficiently large doses are given to produce death, the end comes by failure of the respiratory centre with associated diminution in cardiac power. All the vital forces become greatly impaired, the breathing becomes distant and shallow, and the pulse exceedingly feeble. Like chloroform, hydrated chloral is a dangerous drug when there is fatty degeneration of the heart muscle. Death has resulted from as small a dose as 10 grains (0.60 Gm.).

When hydrated chloral is taken continuously, so that the "chloral habit" is formed, it produces mental hebetude, hallucinations, insanity, emotional disturbances, loss of memory, and extreme physical prostration, and sometimes small sores develop on the skin of the face and elsewhere.

The conditions in which hydrated chloral is best used in medicine are nervous insomnia and insomnia due to nervous irritation, but in both of these classes of patients it should be given with caution lest the habit be produced. In tetanus and strychnine-poisoning it is practically a physiological antidote, since it acts as a powerful depressant upon the motor tracts of the spinal cord, and combined with one of the bromides it is the remedy above all others to be employed in these two conditions.

In the treatment of tetanus and strychnine-poisoning it may be given by the rectum in starch-water, the patient being chloroformed until sufficient time has elapsed for the remedy to be absorbed from the bowels. It may also be used with advantage by the rectum in cases of obstinate vomiting, when it acts by quieting the vomiting centre. Hydrated chloral has often been employed for the control of puerperal convulsions, but it is probably not the best remedy for this condition. Small doses may also be put in cough mixtures.

The treatment of poisoning by this drug consists in the administration of strong black coffee, the hypodermic injection of strychnine, and the administration of Hoffmann's anodyne as a rapidly acting diffusible stimulant. As under the influence of poisonous doses of hydrated chloral there is a great fall of bodily temperature, external heat should be freely applied.

The dose of hydrated chloral varies from 5 to 20 grains (0.30–1.3 Gm.), best given in capsule, followed by a glass of milk, or in equal parts of syrup and water.

Derivatives and Allied Compounds. — CHLORAL-AMYLENE HYDRATE, *Amylene-chloral, Dormiol.* $CCl_3CHOHOC_5H_{11}$.—This compound is obtained by mixing 10 parts of anhydrous chloral with 6 parts of amylene hydrate, and occurs as a colorless oily fluid, having a camphoraceous odor and cooling taste. It is immiscible with cold water, but dissolves with decomposition in boiling water. Alcohol, ether, acetone, and fixed oils dissolve amylene-chloral in all proportions. It is used as a hypnotic. Dose : ½ to 1 drachm (2–4 Cc.) of a 10 per cent. solution.

CHLORAL-AMMONIUM, *Chloralamide* or *Trichloramidoethyl alcohol*, $CCl_3CH(OH)NH_2$, has been suggested as a hypnotic in doses of 15 to 30 grains. It may be obtained by passing a rapid current of dry ammonia through a solution of anhydrous chloral in chloroform as long as it is absorbed, pouring off the chloroform from the crystalline deposit, pressing this between bibulous paper, and drying in vacuo. It occurs as small needle-shaped crystals, which are soluble in alcohol and ether, difficultly soluble in cold water, melt at 83° C. (181.4° F.), and are decomposed at the temperature of boiling water into *Chloralimide*, CCl_3CHNH, and water.

CHLORALOSE. *Anhydro-gluco-chloral.* $C_8H_{11}Cl_3O_6$.—A compound resulting from the union of chloral and glucose, with the elimination of water; thus, $CCl_3CHO + C_6H_{12}O_6 = C_8H_{11}Cl_3O_6 + H_2O$. It is prepared as follows : Equal parts of anhydrous chloral and glucose are heated in a sealed tube or autoclave to 100° C. (212° F.) for about 1 hour, resulting in the production of 2 isomeric compounds, chloralose and parachloralose. The mass after cooling is treated with a little water, and then boiling ether. After distilling the ether-soluble portions 5 or 6 times with water to remove chloral, the isomers are purified and separated by crystallization from water. *Chloralose* was produced by A. Heffter in 1889 and termed *anhydro-gluco-chloral*, and later introduced as the hypnotic chloralose by Hanriot and Richet. It occurs as thin colorless crystals having a bitter taste, soluble in 170 parts of water at 15° C. (59° F.), freely soluble in alcohol, ether, glacial acetic acid, and hot water. Melting-point, 185° C. (365° F.). *Parachloralose* occurs in the form of small colorless scales, insoluble in cold water, slightly soluble in hot water, more soluble in hot alcohol and ether. Melting-point, 229° C. (444.2° F.). It is used as a hypnotic. Dose : 2 to 8 grains (0.1–0.5 Gm.).

CHLORAL-PHENOL, *Carbolated chloral, Chloral-carbol*, is made by triturating equal weights of chloral hydrate and carbolic acid ; it forms a colorless viscid liquid, specific gravity 1.289 at 20° C. (68° F.) ; it possesses prominently the odor of chloral hydrate, has a sweet caustic taste, and produces blisters when placed upon the skin. It is miscible with alcohol, acetic acid, chloroform, carbon disulphide, and ether. Chloral-phenol in small quantities coagulates albumin ; an excess redissolves it. Cotton impregnated with it has been recommended for relief in toothache. J. B. Garrison (1881) prefers for this purpose the firm and short cotton from the cottonwood tree, *Populus canadensis* Michaux ; when saturated with the liquid it is known as *chloro-carbolated cotton.*

SOMNAL. *Ethylated chloral-urethane.*—Under this name a hypnotic was introduced in 1889, which is made by union of chloral, alcohol, and urethane. It melts at 42° C. (107.6° F.), does not react with silver nitrate, and is not acted upon by acids. It is administered in doses of 2 Gm. (30 grains) in aqueous solution flavored with syrup. Half an hour after its administration a sound sleep, lasting from 6 to 8 hours, is produced without any unpleasant after-effects.

CHLORAL-URETHANE. *Ural, Uralium, Uraline.* $C_5H_8Cl_3O_3N$ or $CCl_3COHNH_2COOC_2H_5$. —Melted chloral hydrate is capable of dissolving urethane ; if to such a solution concentrated hydrochloric acid is added, it solidifies within 24 hours to a mass insoluble in water. This is then treated with concentrated sulphuric acid and washed with water, by which an oily liquid results, which subsequently crystallizes. The product is insoluble in cold and decomposed by boiling water ; it is soluble in alcohol and ether, and reprecipitated by water ; its melting-point is 103° C. (217.4° F.). The average dose as a hypnotic is 1 Gm. (15 grains), but its sparing solubility has operated against its use.

CHLORAL HYDROCYANIDE. *Chloral cyanhydrin, Chloral hydrocyanin*, E. ; *Blausäure-Chloral, Chloralcyanhydrat*, G. $CCl_3.CHOHCN$.—This compound was first obtained in 1872 by treating chloral with anhydrous hydrocyanic acid at an elevated temperature. Pinner (1884) suggested to prepare it by dissolving chloral hydrate in a 10 or 12 per cent. solution of hydrocyanic acid obtained from potassium ferrocyanide, equal in weight to that of the chloral hydrate ; the solution after 24 hours is digested for several hours, and finally evaporated on a water-bath. It crystallizes from water in white rhombic plates, melts at 61° C. (141.8° F.), boils with partial decomposition between 215° and 220° C. (419°–428° F.), has an odor recalling that of hydrocyanic acid and chloral, and is readily soluble in water, alcohol, and ether. An aqueous solution of chloralcyanhydrin will remain unchanged for some time, and is not precipitated by silver nitrate, except after heating ; alkalies decompose the salt, yielding chloroform, hydrocyanic and formic acids. It has been recommended as a substitute for hydrocyanic acid, of which it yields 15.5 per cent. ; 1.29 Gm. of chloralcyanhydrin dissolved in 9 Gm. of distilled water furnishes a solution equal in strength to the official 2 per cent. hydrocyanic acid. On adding 0.1 Gm. of "chloral hydrocyanate," 0.2 Gm. of ferric sulphate, and 1 drop

of ferric chloride, to about 5 Cc. of an aqueous solution of sodium hydroxide, the mixture will after a few minutes produce a blue precipitate on acidulating with hydrochloric acid (Hager). The purity of the compound may be determined by estimating the per cent. of hydrocyanic acid. 2 Gm. of the sample with 8 Gm. of a 33.3 per cent. solution of potassium hydroxide and 8 Gm. of sodium thiosulphate are evaporated to dryness on a water-bath, the residue taken up with water, slightly acidulated with sulphuric acid, a sufficient quantity of cupric sulphate added, the solution heated, and the precipitated copper sulphocyanate dried at 110° C. (230° F.). The precipitate multiplied by 0.2077 gives the weight of the hydrocyanic acid (Kaiser and Scharges). Free hydrocyanic acid may be detected in the compound by adding it to a freshly prepared solution of guaiac and copper sulphate (1 part of guaiac resin in 100 parts of absolute alcohol, to which are added a few drops of a dilute aqueous solution of cupric sulphate, 1 part in 8000 of water), a blue color being developed if free hydrocyanic acid is present. It is recommended as a substitute for hydrocyanic acid.

CHLORAL-CAFFEINE.—Prepared by mixing 10 parts of caffeine and 7.8 parts of chloral hydrate in concentrated aqueous or alcoholic solution and evaporating at a moderate temperature. Colorless glistening scales soluble in water and alcohol.

BROMAL HYDRAS. *Bromal hydrate, Tribromaldehyde hydrate.* $C_2HBr_3O+H_2O$. Molecular weight, 298.14.—Bromal (anhydrous) and bromal hydrate are analogous to chloral and chloral hydrate in their preparation and general properties. *Bromal* is prepared by conducting a current of bromine into absolute alcohol, kept cold during the first stage of the operation, and on completion of the reaction the mixture is distilled, and the distillate coming over between 150° and 180° C. (302°–356° F.) collected separately and fractionated by subsequent distillation, yielding the oily liquid *bromal* (tribromaldehyde, C_2HBr_3O), which boils without decomposition at 172°–173° C. (341.6°–343.4° F.), and when mixed with the requisite amount of water forms *bromal hydrate*, $C_2HBr_3O + H_2O$, which is crystallizable from water in the form of large, colorless rhombic crystals, or scales, having a peculiar, pungent, irritating odor and disagreeable, pungent taste. Bromal hydrate melts at 53.5° C. (128.3° F.), is soluble in water, alcohol, ether, chloroform, and carbon disulphide, and is readily decomposed by alkali hydroxides into bromoform and alkali formate. Its aqueous solution (1 in 10) should be clear (absence of bromal alcoholate) and show no turbidity with solution of silver nitrate (absence of bromides). Bromal should not be confounded with *bromol*, a name given to tribromophenol, $C_6H_2Br_3OH$, which is obtained as a colorless or white crystalline powder by the action of bromine on carbolic acid. It is used as a hypnotic and antispasmodic in the dose of from 2 to 15 grains (0.10–1 Gm.).

CHLOROFORMUM, *U. S., Br.*—Chloroform.

Chloroformum purificatum, U. S. 1880; *Trichloromethane, Methenyl trichloride*, E.; *Chloroformium*, P. G.; *Chloroform*, G.; *Formylum trichloratum, Trichlorure de formyle, Chloroforme*, Fr.; *Chloroformio*, It.; *Chloroformo*, Sp.

Formula, $CHCl_3$. Molecular weight, 118.45.

A liquid consisting of 99 to 99.4 per cent. by weight of absolute chloroform, and 0.6 to 1 per cent. of alcohol.—U. S.

Chloroform, or trichloromethane, $CHCl_3$, to which has been added sufficient absolute alcohol to produce a liquid having a specific gravity not less than 1.490, and not more than 1.495.—Br.

It should be kept in dark, amber-colored glass-stoppered bottles, in a cool and dark place.

Chloroform was discovered and prepared in a pure form in 1831 by Samuel Guthrie, Sackett's Harbor, N. Y., and, independently, about the same time, by Liebig, in Germany, and Soubeiran, in France. The pharmacopœias give no process for its preparation. Commercially, it is prepared from alcohol, and in recent years more particularly from acetone by treatment with chlorinated lime, and rarely from chloral by action of an alkali hydroxide.

Preparation.—Chloroform may be prepared from alcohol by mixing 6 parts of chlorinated lime (assaying 30 to 35 per cent. of chlorine) with 24 parts of water, straining the mixture into a still, adding 1 part of stronger alcohol, and heating the mass to 45°–50° C. (113°–122° F.). At this temperature the reaction proceeds rapidly, and as the temperature rises, a mixture of chloroform, alcohol, and water distils over, the distillate on completion of the distillation consisting of two layers, the lower of which is removed and thoroughly washed with water, and then repeatedly with concentrated sulphuric acid, until the acid is no longer discolored. The washed chloroform is then treated with a solution of sodium carbonate, again washed with water, and finally dehydrated with suitable dehydrating agents (fused calcium chloride, fused potassium carbonate, or phos-

phoric anhydride, etc.) and subjected to fractional distillation, the first fractions separated and the fractions distilling between 59° and 62° C. (138.2–143.6 F.) collected as chloroform, and, if desired, subjected to further purification by redistillation, refrigeration (process of Pictet), or crystallization with salicylide, etc. (process of Anschütz).

The reaction taking place between the alcohol and the chlorinated lime is a very complex series of chemical reactions, but may be summarized into the successive productions of aldehyde, chloral, and chloroform, as illustrated in the following equations: $2C_2H_6O$ (alcohol) + $Ca(OCl)_2$ (calcium hypochlorite) = $2C_2H_4O$ (aldehyde) + $CaCl_2$ + $2H_2O$; $2(C_2H_4O)$ (aldehyde) + $3Ca(OCl)_2 = 2(C_2HCl_3O)$ (chloral) + $3Ca(OH)_2$ (calcium hydrate); $2(C_2HCl_3O)$ (chloral) + $Ca(OH)_2$ (calcium hydrate) = $2(CHCl_3)$ (chloroform) + $Ca(CHO_2)_2$ (calcium formate).

For papers on the manufacture of chloroform, see *Am. Jour. Pharm.*, 1862, pp. 25, 42; 1868, p. 289; 1889, p. 321; Squibb's *Ephemeris*, vol. iv. No. 4, pp. 1743–1757; *Proc. Am. Pharm. Assoc.*, vol. xli. p. 909; xliv. p. 757; xlv. p. 660; xlvii. p. 535; xlviii. p. 767.

Preparation from Acetone.—Although Liebig had shown in 1832 that chloroform could be made from acetone by treatment with chlorinated lime, and the condition of its formation were well understood (Bonnet, 1837; Böttger, 1848), it appears that the commercial manufacture of chloroform from acetone or acetates did not come into prominence until about 1885, since which time acetone and acetates have been the most economical source of commercial chloroform. Acetone when treated with chlorinated lime under the proper conditions yields 180–200 per cent. by weight of chloroform. 10 parts of acetone diluted with 30 parts of water are gradually and with constant stirring introduced into a mixture of 100 parts of chlorinated lime (30 to 35 per cent. of available chlorine) and 300 parts of water contained in a suitable retort, and the whole subjected to distillation. The resultant product is purified as above. The chemical reaction is explained in the intermediate formation of trichloracetone as follows: $2C_3H_6O$ (acetone) + $3Ca(OCl)_2$ (chlorinated lime) = $2C_3H_3OCl_3$ (trichloracetone) + $3Ca(OH)_2$; $2(C_3H_3Cl_3)$ (trichloracetone) + $Ca(OH)_2 = 2CHCl_3$ (chloroform) + $Ca(C_2H_3O_2)_2$ (calcium acetate).

An electrolytic process has been devised (L. Lambellati, *L'Elettricita*, 1899, p. 664) in which an electric current of about 5 or 6 ampères is passed through carbon stirrers, serving as an anode, into a hot aqueous 20 per cent. solution of sodium or calcium chloride, while acetone is being introduced into the bottom of the leaden still which serves as the cathode. Chlorine and sodium hydroxide are generated by the electric current. The chlorine converts the acetone into trichloracetone, and this in turn is decomposed by the alkali hydroxide, producing chloroform and acetate, according to the equation: $C_3H_3OCl_3$ (trichloracetone) + NaOH = $CHCl_3$ (chloroform) + $NaC_2H_3O_2$ (sodium acetate).

At the present time but little chloroform is obtained on a commercial scale by the action of sodium hydroxide on chloral hydrate. 165 parts of the latter are capable of yielding 119 parts of chloroform, as shown by the equation: $C_2HCl_3O.H_2O$ (chloral hydrate) + NaOH = $CHCl_3$ (chloroform) + $NaCHO_2$ (formate) + H_2O.

A new (1896) method has been introduced for making chloroform from tetrachlormethane, CCl_4. 75 parts of tetrachlormethane are subjected to the action of nascent hydrogen generated from the action of 60 parts of hydrochloric acid (22° B.) and 50 parts of zinc, the reaction being as follows: CCl_4 (tetrachlormethane) + 2H = $CHCl_3$ (chloroform) + HCl.

Chautart proposed to prepare chloroform from oil of turpentine, but Soubeiran proved that chlorinated lime diffused in water acts violently upon the oil, and that but a little chloroform having a turpentine odor is obtained. Damoiseau (1881) suggested that pure chloroform may be advantageously prepared by passing a mixture of methyl chloride, CH_3Cl, and chlorine in proper proportion through a long tube containing animal charcoal and heated to between 250° and 350° C. (482°–662° F.).

Purification.—Chloroform which fails to respond to the pharmacopœial tests, may be purified by the following process: Chloroform, 400 Gm.; sulphuric acid, 80 Gm.; dried sodium carbonate, 20 Gm.; deodorized alcohol, 4 Cc.

Add the sulphuric acid to the chloroform, contained in a glass-stoppered bottle, and shake them together occasionally during 24 hours, avoiding exposure to bright daylight. Separate the lighter chloroform layer, add to it the dried sodium carbonate, previously rendered anhydrous by heating it in a porcelain capsule on a sand-bath until it ceases to give off aqueous vapor, and shake them together frequently and thoroughly during half

an hour. Then transfer the chloroform to a dry retort, add to it the alcohol, and distil, by means of a water-bath, at a temperature not exceeding 67.2° C. (153° F.), into a well-cooled receiver, until the distillate measures 255 Cc.

Special methods have recently been proposed for the preparation of chemically pure chloroform, notably that of Pictet by means of refrigeration to —82° C. (—147.6° F.), at which point the pure chloroform is obtained in solid form, to be subsequently distilled at a low temperature under reduced pressure. R. Anschütz (1892) proposed the formation of a salicylide-chloroform, to be obtained in crystallized form by allowing salicylide, C_6H_4COO, and also ortho-homosalicylide, $CH_3C_6H_4COO$, to remain in contact with chloroform for 24 hours; the compounds, which contain 33.24 and 30.8 per cent. of chloroform respectively, may be kept in closed vessels for a long period, and readily yield the chloroform by distillation, the union being a feeble one and comparable with water of crystallization. None of the impurities have been found to form crystallizable compounds with salicylide or ortho-homosalicylide, and the latter substances may be used repeatedly in this process.

The chloroform manufactured by the different methods when properly purified cannot be distinguished one from the other, so that we are limited to chemical tests to determine its fitness for anæsthetic and other purposes.

Properties.—Pure (absolute) chloroform is a heavy, colorless, mobile, and diffusible liquid, not inflammable, of an agreeable characteristic ethereal odor, a hot sweetish taste, of neutral reaction, volatilizes at ordinary temperature, and boils at 62° C. (143.6° F.). Its specific gravity at 15° C. (59° F.) is 1.502. It is soluble in about 200 parts of water, to which it imparts its taste and odor, and is miscible in all proportions with alcohol, ether, benzene, benzin, and fixed and volatile oils. It is a solvent for paraffin, guttapercha, camphor, caoutchouc, many resins, most alkaloids, iodine (with violet color), bromine (with brown color), and considerable phosphorus and sulphur. Concentrated sulphuric acid or nitric acid at ordinary temperatures does not affect chloroform, but a mixture of these acids will, on heating them with chloroform, produce *nitrochloroform*, CCl_3NO_2, an oily liquid boiling at 112° C. (233.6° F.), and of a strong, irritating odor. Heated with alcoholic potassium hydroxide and a little resorcin, chloroform yields a reddish-yellow solution with strong greenish fluorescence. Boiled with a concentrated aqueous solution of potassium hydroxide and α- or β-naphtol, a blue color is produced which on exposure to air turns green and finally brown.

On heating chloroform with strong aqueous solution of potassium or sodium hydroxide, it is slowly decomposed, rapidly in presence of much alcohol, into chloride and formate of the alkali metal. It reduces Fehling's Solution. Heated with alcoholic potassium hydroxide solution and a little aniline, it produces "isonitril" (benzo-isonitril, phenyl-isonitril), recognized by its peculiar odor. and readily distinguishing chloroform from ethylene chloride, $C_2H_4Cl_2$, which fails to give the reaction. The vapor of chloroform passed through a red-hot tube yields chlorine, and, in conjunction with hydrogen under the same conditions, hydrochloric acid. Chloroform solidifies, or crystallizes, when cooled to —80° C. (—112° F.), the crystals melting again at —70 C. (—94° F.). It forms crystalline compounds with salicylide (see above) and homosalicylide; with *colchicine* ($C_{22}H_{25}NO_6.2CHCl_3$), Zeisel; with *berberine* (E. Schmidt), and with *lebrain* ($C_{19}H_{18}O_9$-$CHCl_3$), G. Kassner, *Arch. d. Pharm.*, 239, 47. Chloroform does not coagulate albumin. It acts as an antiseptic and bactericide, and has for this reason been used as a test to distinguish chemical and living ferments, the former not being affected, while it checks the action of the latter (*Pharm. Jour.*, 1874, pp. 441, 442, 455). It is a powerful anæsthetic, and as such has some advantage over ether, as its vapors are not inflammable, although on coming in contact with a naked flame a disagreeable and irritating odor may be developed on account of the liberation of chlorine. Paper saturated with chloroform and ignited burns with a green flame along the line of charring of the paper.

In the pure state chloroform is very prone to decompose when exposed to air and light, liberating chlorine, hydrochloric acid, phosgene ($COCl_2$), and other products. Oxygen is essential to its decomposition by light. Its tendency to decompose is overcome by the addition of oxidizable substances. Thus, sulphur (L. Allain, *Jour. de Pharm* (6), xv. 252), and poppy-seed oil (V. Masson, loc. cit. (6), ix. No. 12), in quantities as small as 0.1 per cent., were found sufficient to keep chloroform unchanged for months. Alcohol acts similarly as a preservative.

Pharmacopœial Chloroform.—Owing to the tendency of pure chloroform to decompose on exposure to light, commercial and pharmacopœial chloroform contains alcohol a

a preservative. 0.5 to 1 per cent. of alcohol suffices to prevent decomposition, and its addition within these limits has been adopted by the various pharmacopœias (0.4 to 0.7 per cent., Br.; 0.6 to 1 per cent., U. S. P.; 0.7 to 1 per cent., G. P.) for this purpose, although various observers have shown that 0.6 per cent. of alcohol will suffice to keep chloroform for over a year without perceptible evidence of decomposition. The addition of alcohol lowers both the specific gravity and the boiling-point. Biltz gives the following for additions of alcohol up to 2 per cent.:

Alcohol added.	Specific gravity at 15° C.	Boiling-point.
0.25 per cent.	1.4977	61.3°–61.9° C.
0.50 "	1.4939	61.07–61.8
1.0 "	1.4854	60.27–61.6
2.0 "	1.4705	59.7 –61.2

The pharmacopœial requirements are for specific gravity: U. S. P., not below 1.476 at 25° C. (77° F.); the P. G., 1.485 to 1.489; the Br. P., 1.490 to 1.495; and the boiling-points being: U. S. P., 60° to 61° C. (140°–141.8° F.); P. G. and Br. P., 60° to 62° C. (140°–143.6° F.).

The solubilities and general properties of pharmacopœial chloroform differ but very slightly from those given under pure (absolute) chloroform (see above), the slight differences being due to the small percentage of added alcohol. The purity of commercial chloroform is readily determined by the U. S. P. tests, and chloroform which does not pass these tests should not be used for anæsthetic purposes.

Tests.—If 10 Cc. of chloroform be poured upon a clean odorless filter laid flat upon a warmed porcelain or glass plate, and the plate be rocked from side to side until the liquid is all evaporated, no foreign odor should become perceptible as the last portions disappear from the paper, and the paper should be left odorless. If 10 Cc. of chloroform be well shaken with 20 Cc. of distilled water, and the liquid be allowed to separate completely, the water should be neutral to litmus-paper, and should not affect silver nitrate test-solution (absence of chlorides) nor potassium iodide test-solution (absence of free chlorine). If 40 Cc. of chloroform be shaken with 4 Cc. of colorless, concentrated sulphuric acid (absolutely free from chlorine compounds) in a 50 Cc. glass-stoppered cylinder during 20 minutes, and the liquids be then allowed to separate completely, so that both are transparent, the chloroform should remain colorless, and the acid should appear colorless or very nearly colorless when seen in a stratum of not less than 15 Mm. in thickness (absence of impurities decomposable by sulphuric acid). If 2 Cc. of the sulphuric acid, separated from the chloroform, be diluted with 5 Cc. of distilled water, the liquid should be colorless and clear, and, while hot from the mixing, should be odorless or give but a faint vinous or ethereal odor (absence of odorous decomposition-products). When further diluted with 10 Cc. of distilled water it should remain clear, and should not be affected by silver nitrate test-solution (absence of chlorinated decomposition-compounds).—U. S.

The decomposition by alkali hydroxide solution may be used as the basis for the quantitative estimation of chloroform in liquids. Puckner (*Proc. Am. Pharm. Assoc.*, 1901, pp. 294–297) gives the following method: To 10 Cc. of an approximately normal alcoholic solution of potassium hydroxide, either free from chloride or else of a known chloride content, and contained in a vial, add a measured volume of the chloroform mixture representing from 0.05 to 0.2 Gm. of chloroform, stopper with a sound cork, cover with cloth and tie this down firmly, mix the liquids by rotation, then place the vial in boiling water in such a way that at no time the contents come in contact with the cork, and maintain the temperature for 3 hours. Remove the vial from the bath, let cool, add phenolphtalein, and then sufficient sulphuric acid to exactly neutralize the liquid, then add 2 drops of potassium dichromate test-solution and titrate with decinormal silver nitrate. 1 Cc. of decinormal nitrate represents 0.003969 Gm. of $CHCl_3$. Chloroform may readily be recovered from blood, tissues, and liquids for identification by adding a few Cc. of alcohol to the test-object, and, after acidulating with tartaric acid, subjecting the whole to gentle distillation, and applying to the distillate the tests given above under *Properties*, for its identification.

Action and Uses.—Locally applied to the skin and prevented from evaporation by a cloth or a watch-glass, chloroform is capable of producing a blister, and, given hypodermically, of causing a slough. Taken internally in overdose, it is capable of producing death in the same manner as it causes death when taken in overdose by inhalation. Much discussion has arisen as to the mode by which chloroform produces death when taken by inhalation. When it is taken by inhalation for the production of surgical

anæsthesia and an accident occurs, there can be no doubt that its primary influence is exercised as a depressant upon the vasomotor system, causing the patient to be bled into his own bloodvessels, so that the vital centers are starved of blood. In unduly susceptible persons or in those having myocardial disease, it probably causes death by direct depression of the heart muscle, and in still others it may cause death by respiratory failure, for chloroform is a depressant poison to all living protoplasm with which it comes in contact in concentrated form. As its odor is not disagreeable and its vapor is not irritating when mixed with a proper amount of air, it is a more agreeable anæsthetic than ether, and it is possible sometimes to anæsthetize a sleeping patient without awaking him. Properly administered, chloroform is capable of producing surgical anæsthesia within a few moments after its inhalation commences. This anæsthesia depends upon its influence upon the peripheral centers in the posterior portions of the brain. The influence of the drug ought never to be carried to the point of complete muscular relaxation. The fact that it is a much more agreeable anæsthetic than ether has led many practitioners to employ it, but the death-rate from accidents under its use is about 1 in 3000; while the death-rate from accidents in the use of ether is about 1 in 13,000. While, therefore, it is our belief that ether is the anæsthetic of choice in the majority of instances, there can be no doubt that chloroform has a very large field of usefulness, and ought to be employed for all persons who are known to take ether badly and in cases of Bright's disease, since it does not irritate the kidney as much as does ether, because of the small quantity of it which is necessary to produce anæsthesia. Because of the rapidity of its action and its small bulk, it is the anæsthetic of choice on the battlefield.

Chloroform has been largely used by obstetricians for relieving the pains of labor, and has rarely produced death when used for this purpose, so that many practitioners regard it as the anæsthetic of choice during parturition. In puerperal convulsions, when they are exceedingly severe and cannot otherwise be controlled, chloroform may be used as a rapidly acting relaxant, and the bromides or veratrum viride may also be employed. Whiffs of it may be used in cases of severe angina pectoris, although this practice is not without danger.

It is a noteworthy fact that many of the accidents with chloroform have occurred during the first inhalations of the drug.

When chloroform vapor in the air comes in contact with a gas-flame, it is decomposed and sets free fumes of chlorine and hydrochloric acid, which cause great irritation of the respiratory passages. The drug should always be kept in dark bottles, well corked, as it is capable of undergoing decomposition-changes which increase its dangerous properties. The best inhaler for its use is that which is known as Esmarch's inhaler.

Taken internally, chloroform, in the dose of from 3 to 5 minims (0.20–0.30 Cc.), well diluted with water, is an excellent remedy for wind colic and abdominal pain; or the spirit of chloroform may be used in the dose of from 1 to 2 fluidrachms (4–8 Cc.), well diluted with water or with equal parts of spirit of camphor and water, for the same purpose.

Allied and Derivative Compounds.—BROMETONE, or TRIBROM-TERTIARY-BUTYL-ALCOHOL, $C_4H_7OBr_3$ or $(CH_3)_2COHCBr_3$.—This compound is said to be obtained as a condensation-product by the action of caustic alkalies on a mixture of bromoform and acetone. It occurs in fine white prismatic crystals having a camphoraceous odor and taste. Brometone melts at about 167° C. (332.6° F.) and is slightly soluble in cold and more soluble in hot water; also quite soluble in alcohol, ether, benzin, etc.

CHLORETONE, or TRICHLOR-TERTIARY-BUTYL-ALCOHOL, $C_4H_7OCl_3$ or $(CH_3)_2COHCCl_3$.—This is prepared in a manner similar to the preceding compound, except that chloroform is used in place of bromoform. Like bromoform, it occurs in beautiful snow-white crystals with camphor-like odor and taste. It is very soluble in alcohol, ether, and chloroform, also freely soluble in glycerin, volatile and fixed oils, benzin, and acetone. Warm water dissolves chloretone to the extent of 1 per cent., but on cooling a portion crystallizes out, leaving a saturated solution of about 0.8 per cent. strength. Chloretone is unaffected by heat or light and under ordinary conditions of exposure its solutions are permanent. Chloretone is a hypnotic and local anæsthetic. It produces sedation of the central nervous system, and is non-irritant, non-toxic, and without effect upon the heart. It is a useful remedy in nausea, especially that of chloroform or ether anæsthesia and seasickness. Combined with an equal quantity of boric acid it forms an excellent dusting-powder for wounds, ulcers, bedsores, etc.; and its solution in liquid petrolatum along with menthol and aromatic oils affords relief in irritable conditions of the nasal, pharyngeal, and bronchial mucous membranes. The dose as a hypnotic is from 5 to 20 grains (0.30–1.30 Gm.).

CHONDRUS, *U. S.*—Irish Moss.

Carrageen, P. A., P. G.; *Killeen, Pig-wrack, Pearl-moss*, E.; *Fucus crispus, Lichen Hibernius*, Russ.—*Carragaheen, Mousse perlée*, Fr. Cod.; *Irländisches Moos, Perlmoos, Knorpeltang*, G.; *Fuco carrageo*, F. It.; *Musgo d'Irlande, Fuco crispa*, It.; *Caragaheen, Musco marine perlado*, Sp.; *Alga perlada, Musgo Branco*, Port.

The dried plant of *Chondrus crispus* (L.) Lyngbye (*Fucus c.* L.—Fam. *Gigartinaceæ*).

Chondrus is official in nearly all pharmacopœias.

Origin.—The plant grows on submerged rocks along the north Atlantic, and is collected on both the European and American coasts. It is dried and bleached on the sand, the operation requiring about two weeks. Meantime, it has to be daily sprinkled with sea-water and turned over, and to be kept from contact with fresh water. Two grades are recognized, respectively, from the spring and summer collections, the former being superior. The later crop is apt to be attacked by a sort of black mildew.

Description.—Usually less than 15 Cm. (6 In.) long, repeatedly forking from a short, cylindraceous base, the ultimate segments either linear or short and broad, blunt, scarcely acute, the summit notched or slightly 2-lobed; mass light-yellow or yellowish-white, highly elastic, cartilaginous, of a slight saline odor and taste, very mucilaginous, not astringent or bitter. Not more than 17 per cent. of ash should be yielded upon incineration.

1 part boiled for 10 minutes with 30 parts of water yields a gelatinous mass, when cold, which is not colored blue by iodine test-solution.

Fig. 103.

Chondrus crispus: broad form.

Fig. 104.

Narrow form, with fruit.

Fig. 105.

Gigartina mamillosa: with fruit.

Constituents.—Chondrus gives from 55 to 90 per cent. of a pectin-like mucilage, called *carrageenin*, of which only part is soluble in cold water; also traces of iodine and bromine, and some sulphur. Starch is absent. There is about 1 per cent. of nitrogen, chiefly in the mucilage.

Pharmaceutical Preparations.—Compound Syrup of Chondrus (Irish Moss), N. F.; Mucilage of Irish Moss, N. F.

Action and Uses.—Irish moss is demulcent and slightly nutritious. It was at one time largely employed in the treatment of chronic pulmonary and bronchial affections and in disordered conditions of the intestinal tract. It was also recommended in chronic disorders of the kidneys and bladder, but is now rarely used.

Carrageen is usually administered in the form of a decoction. The drug should be macerated in cold water for 15 minutes in order to separate any impurities which may be present. One-half ounce (16 Gm.) is then added to 1½ pints (720 Cc.) of water and boiled down to 1 pint (480 Cc.). This is flavored with lemon and sugar, and given in doses of 1 fluidounce (30 Cc.) several times daily.

Allied Drugs.—Dulse is the name given to *Halymenia* (*Fucus* L., *Rhodomenia* Greville, *Sphærococcus* Kützing) *palmatus* and *edulis* Agardh, 2 florideous algæ growing on the coasts of the Atlantic and Mediterranean. Both are of a deep blood-red, or after drying dark-purple, color, and have flattened fronds, that of the first species being palmately divided into oblong, wedge-shaped lobes. Stenhouse (1844) found it to contain mannite, and Magin-Bonet proved the presence of bromine and iodine.

Helmintiiochorton, Corsican Moss; *Mousse de Corse*, Fr. Cod.—This consists partly of *Sphærococcus* (*Fucus* L., *Ceramium* Willd., *Gigartina* Lamouroux, *Alsidium* Kützing) *Helminthochorton* Agardh, which grows in the Mediterranean, but as found in commerce is always a mixture, sometimes of 20 or 30 different species of algæ. The drug is cartilaginous, filiform, repeatedly forked, varies in color between brown, yellowish, and whitish, and has the odor of seaweeds and a strongly saline and mucilaginous taste. It contains mucilage and various salts, among them bromides and iodides, but its anthelmintic principle, if any, is unknown.

Fucus amylaceus, Ceylon Moss, also called *Jaffna* and *Edible moss*, comes from the Indian Ocean, and consists of *Sphærococcus* (*Plocaria* Montag, *Gracilaria* Greville) *lichenoides* Agardh. It is about 10 Cm. (4 In.) or more long, about 1.5 Mm. ($\frac{1}{16}$ In.) thick, cylindrical, irregularly forked, filiform above, and has in the fresh state a reddish color, but on drying becomes nearly white and rather brittle. It has a slight seaweed odor and a mucilaginous taste. H. G. Greenish (1882) found in it moisture 15, ash 10.2, albuminoids 7.5, and matter soluble in alcohol 0.1 per cent., and determined the absence of mannite and the presence of various carbohydrates differing in their behavior to water and alkalies and in the sugar they yield with acids, namely, metarabin 1.32, and others soluble in soda solution 3.12, gelose and others soluble in hot water 36.7, paramylon 6.5, wool-gum 3.2, and cellulose 10.2 per cent.

CHROMII TRIOXIDUM, *U. S.*—Chromium Trioxide.

Acidum chromicum, U. S., 1890, Br., P. G.—*Chromic acid, Chromic anhydride*, E.; *Acide chromique*, Fr.; *Chromsäure*, G.; *Anidride cromica*, F. It.; *Acido cromico*, It., Sp.

Formula, CrO_3. Molecular weight, 99.34.

Chromium trioxide should contain not less than 90 per cent. of chromic anhydride. It should be kept in glass-stoppered bottles, and great caution should be observed to avoid bringing it in contact with organic substances, as cork, tannic acid, sugar, alcohol, etc., since dangerous accidents are liable to result.—U. S.

Preparations.—This acid was discovered by Vauquelin in 1797, but its chemical composition was determined by Berzelius.

When a concentrated solution of potassium dichromate is acted upon by strong sulphuric acid, chromium trioxide is set free, as shown by the following equation: $K_2Cr_2O_7 + 2H_2SO_4 = 2CrO_3 + 2KHSO_4 + H_2O$; this is due to the fact that chromic acid proper (H_2CrO_4) cannot exist in a free state. When prepared by the ordinary methods, chromic acid usually is contaminated with sulphuric acid and potassium salts, the former rendering it very hygroscopic. Inasmuch as the U. S. and German Pharmacopœias demand chromic acid free from sulphuric acid, it is likely that the following plan, first suggested by Bunsen (1868), is now more generally used: 30 parts of potassium dichromate, 50 parts of water, and 77.5 parts of concentrated sulphuric acid are heated together to complete solution and let stand for 12 hours. The crystals of potassium bisulphate formed are removed on an asbestos filter and the liquid heated to 85° C. (185° F.). 27.5 parts of concentrated sulphuric acid are then added in small portions while stirring, and just sufficient water to redissolve any crystals of chromic acid that may be formed; the whole is left standing 12 hours in a cool place. The crystals are then drained on an asbestos filter, dried on a porous plate, washed with small quantities of nitric acid, dried again on plates, and finally at 60°–80° C. (140°–176° F.), to remove nitric acid.

Properties.—Chromium trioxide forms small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic lustre; odorless; destructive to animal and vegetable tissues; deliquescent in moist air. Very soluble in water, forming an orange-red solution. When brought in contact with alcohol, ether, glycerin, and other organic solvents, decomposition takes place, sometimes with dangerous violence. When chromium trioxide is heated, its color darkens, and finally becomes black, but is restored on cooling. At 192° to 193° C. (377.6°–379.4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating, leaves a

residue of pure chromic oxide, which should yield nothing soluble to water (U. S.). When contaminated with sulphuric acid, the color of chromium trioxide is scarlet red.

A concentrated solution is of a red-brown color, which changes to orange yellow on being diluted; the dilute solution reddens blue litmus-paper and bleaches it on drying. If strong alcohol is dropped upon chromium trioxide, a vigorous action takes place, accompanied with increase of temperature and ignition of the alcohol. A rapid ignition is observed likewise with benzene; but ether which is free from both alcohol and water dissolves this compound, and on spontaneous evaporation yields it again in minute crystals. Chromium trioxide dissolved in diluted alcohol is deoxidized gradually at the ordinary temperature, the alcohol being converted into aldehyde and acetic acid. Reduction takes place also in the presence of arsenous and sulphurous acids, hydrogen sulphide, and of organic compounds and deoxidizing agents generally. When heated with hydrochloric acid, chlorine and green chromic chloride are produced. In all these cases the CrO_3 passes into Cr_2O_3 or its salts.

Dissolved in water, chromium trioxide forms chromic acid, H_2CrO_4, the salts of which have mostly a yellow or yellowish-red color; those of the alkalies—magnesium, calcium, zinc, and copper—are soluble in water; all others dissolve in nitric acid.

Tests.—A solution of 1 Gm. of chromium trioxide in 100 Cc. of water, previously acidulated with a few Cc. of hydrochloric acid, should not be rendered turbid on the addition of 1 Cc. of barium chloride test-solution (absence of sulphuric acid). If 1 Gm. of chromium trioxide be dissolved in 100 Cc. of water, and 8.3 Cc. (8.28 Cc.) of this solution measured into a glass-stoppered bottle of about 100 Cc. capacity, followed by 20 Cc. of water, 2 Cc. of hydrochloric acid, and about 1 Gm. of potassium iodide, after securely closing and shaking for a few minutes, and adding 1 Cc. of starch test-solution, not less than 22.5 Cc. of tenth-normal sodium thiosulphate test-solution should be required to discharge the blue color, the remaining solution retaining a greenish color (each Cc. of the volumetric solution indicating 4 per cent. of pure chromium trioxide). —U. S.

Action and Uses.—Chromium trioxide is practically never employed internally, but may be given in doses of ¼ grain (0.015 Gm.). It has been used largely as an antiseptic and caustic, but at present its use is confined almost exclusively to the removal of small growths, such as warts, from the skin and condylomata from the external genitals. For this purpose it may be applied in the form of a solution containing 100 grains (6.6 Gm.) of the acid to 1 fluidounce (30 Cc.) of water. Care should be exercised in its application, for if applied over too large a surface it may cause poisoning and death, or produce sloughing. Deliquesced chromium trioxide may be applied to hypertrophied turbinated bones, but at present is used less largely than formerly for this purpose, because of the violent headache which sometimes follows its application. A solution of the drug applied to the bases of nasal and post-nasal polypi, after their removal by mechanical means, is said to prevent recurrence.

CHROMIUM.—Chromium.

Symbol, Cr. Atomic weight, 51.7. Valence variable: 2 in chromous salts, 3 in chromic salts, 6 in chromic acid.

Chromium was isolated in 1797 by Vauquelin in native lead chromate which had been discovered in 1762 in Siberia by Lehman. The name is derived from *χρωμα*, color, and was assigned because all the compounds of chromium were found to be highly and variously colored. The chief ore of chromium is chrome-iron ore, $Cr_2O_3.FeO$. It was formerly difficult to reduce the oxide to the metallic state, but it can now be readily done by igniting a mixture of the oxide and aluminum filings (Goldschmidt), or by reducing the oxide with carbon in the electric furnace.

Chromium is a steel-gray metal, fusible only in the oxyhydrogen flame or electric arc, and very hard, soluble in hydrochloric and hot sulphuric acids, but not in nitric acid. Several alloys of chromium are valuable, particularly ferro-chrome, which is used in the manufacture of steel. Chromium forms 2 well-defined oxides: chromic oxide (sesquioxide), Cr_2O_3, which is dark-green and gives rise to the chromic salts; and chromium

trioxide, CrO_3, which has been described under CHROMII TRIOXIDUM. Although chromous oxide, CrO, does not exist in the free state, salts derived from it are known. Chromium salts as well as soluble chromates are used extensively in the industries; at present, chromium hydroxide is the most important mordant for fixing dyes on fabrics, since chrome lakes are much superior to aluminum lakes in color and fastness. The chromium hydroxide is precipitated on the fibers either from chromium salts by an alkali or from chromates by reducing agents, and there forms an insoluble compound with dyes. Chromates or dichromates are also used in a new process for tanning by which the time is very much shortened.

Action and Uses.—Chromium is never employed in medicine. For its properties and uses, see CHROMII TRIOXIDUM and POTASSII DICHROMAS.

COMPOUNDS OF CHROMIUM.

Chromii Acetas.—*Chromium acetate*, E.; *Chromiacetat*, G. $Cr(C_2H_3O_2)_3$.—This occurs in commerce as a dark-green solution, which decomposes into chromium hydroxide and acetic acid when heated. It is employed in dyeing.

Chromii Chloridum.—*Chromium chloride*, E.; *Chrom-chlorid*, G. $CrCl_3$.—Obtained as a green solution when chromium hydroxide is dissolved in hydrochloric acid. From very concentrated solution, the salt crystallizes with varying quantities of water.

Chromous Chloride, $CrCl_2$, is obtained by heating chromic chloride in hydrogen, or chromium in hydrochloric acid gas. In the anhydrous state it is white, but in solution it is sky-blue. It is a marked reducing agent, and hydrochloric acid solution is used to absorb oxygen.

Chromii Fluoridum.—*Chromium fluoride*, E.; *Chrom-fluorid*, G. $CrF_3 + 4H_2O$.—This salt and other double salts containing it are of commercial value as mordants in dyeing because they easily decompose in aqueous solution, giving chromium hydroxide.

Chromii Sulphas.—*Chromium sulphate*, E.; *Chromi-sulfat*, G. $Cr_2(SO_4)_3 + H_2O$.—This is obtained by dissolving chromium hydroxide in sulphuric acid. It forms bluish-violet octahedra, which dissolve with a violet color. On heating the solution, it turns green, and on evaporation a green amorphous mass is obtained. This green modification, on long standing in solution, passes into the violet form.

Chromii et Potassii Sulphas.—*Alumen Chromicum.*—*Chrome alum*, *Chromium-potassium sulphate*, E.; *Chrom-Alaun*, *Chromi-Kaliumsulfat*, G. $CrK(SO_4)_2 + 12H_2O$.—This very important and much used salt is obtained generally as a by-product in industries where organic compounds, as anthracene, etc., are oxidized by potassium dichromate. For experimental purposes, it may be made by dissolving 10 parts of potassium dichromate in 40 parts or more of water, adding 14 parts of concentrated sulphuric acid, and passing sulphur dioxide through the solution until it is in excess. The temperature should not rise above 40° C. (104° F.), otherwise the green chromium sulphate noted above will be formed, which prevents crystallization of the chrome-alum. The reaction is $K_2Cr_2O_7 + H_2SO_4 + 3H_2SO_3 = 2KCr(SO_4)_2 + 4H_2O$; the change consists in a reduction of chromium trioxide in the dichromate to chromium sesquioxide: $2CrO_3 + 3H_2SO_3 = Cr_2O_3 + 3H_2SO_4$. The sesquioxide in the presence of sulphuric acid forms chromium sulphate, which with potassium sulphate, formed at the same time, gives chrome-alum, a double salt analogous to ordinary alum. Chrome-alum forms dark-violet, large, octahedral crystals, soluble in 5 parts of water, the solution turning green when heated. Ammonia water added in excess to the solution precipitates bluish-green chromium hydroxide, $Cr(OH)_3 + 2H_2O$, which is the starting-point for making various chromium salts. When heated to a high temperature, the hydroxide forms a green oxide. This is manufactured as a green pigment.

Gingnet's Green, $Cr_2O_3.2Cr(OH)_3$, is obtained by heating potassium dichromate and borax and extracting the mass with water.

CHRYSAROBINUM, *U. S., Br., P. G.*—Chrysarobin.

Araroba Depurata; *Chrysarobin*, G.; *Chrysarobine*, Fr.; *Crisarobina*, It.; *Chrysarobina*, Sp.

A neutral principle extracted from Goa powder, a substance found deposited in the wood of *Vouacapoua Araroba* (Aguiar) Druce (*Andira a.* Aguiar, Fam. *Leguminosæ*).

Chrysarobin is obtained from Araroba by extraction with hot chloroform, evaporating the solution to dryness, and powdering.—Br.

Origin.—The *Po' de Bahia*, *Araroba* or *Arariba tree*, is closely allied to the West Indian cabbage tree, and is common in the damp forests of Bahia, Brazil, where it is

locally known as *Angelim Amargoso*. It is a large forest-tree, with pinnate leaves and panicles of purple bean-like flowers, and much resembles the copaiba tree. The native name araroba is applied to a number of related Brazilian trees of this and other genera, and is subject to confusion.

The araroba is contained in the large porous vessels, and in clefts or cavities which traverse the wood in the direction of the diameter and are prolonged through the entire trunk. It is apparently deposited as an antiseptic preservative provision by the plant, and results from chemical changes in the cell-walls. It is obtained by cutting down the tree, splitting the trunk, and scraping the powder from the clefts, and is seen in commerce as a rough powder or in small irregular pieces, originally of a light-yellow color, but usually darkened by exposure to light and moisture to a dull-ochrey, pale-brown, or even umber-brown or deep-purple color. It has a bitter taste. When carefully heated, it yields a moss-like sublimate, which is colored red by alkalies.

Araroba is recognized in the Br. P., and is also there designated as crude chrysarobin. It received its name of "Goa powder" from having been originally shipped by the Portuguese settlers in Brazil to their countrymen in the province of Goa, East Indies.

Properties and Tests.—Chrysarobin occurs as a pale orange-yellow, microcrystalline powder, tasteless, odorless, and irritating to the mucous membrane. Its specific gravity varies between 0.920 and 0.922. At 25° C. (77° F.) it is soluble in 4812 parts of water, 308 parts of alcohol, 25 parts of benzene, 18 parts of chloroform, 114 parts of ether, 30 parts of amyl alcohol, and 230 parts of carbon disulphide; also soluble at 80° C. (176° F.) in 2170 parts of water, at 60° C. (140° F.) in 275 parts of alcohol. With dilute or concentrated solutions of potassium hydroxide, it forms a red-colored liquid with green fluorescence. Chrysarobin contracts and forms a dark mass at 148° C. (298.4° F.) and melts at 157° C. (314.6° F.). When ignited it is partly sublimed and finally entirely consumed. It dissolves in sulphuric acid, forming a deep-red solution. On pouring this liquid into water, chrysarobin is deposited unchanged. On mixing 0.001 Gm. of chrysarobin with 2 drops of fuming nitric acid, a red-colored mixture is produced, which turns violet on the addition of a few drops of ammonia-water (distinction from chrysophanic acid, which produces a yellow-colored liquid). On shaking chrysarobin with lime-water for a few minutes, the liquid acquires a violet color (distinction from chrysophanic acid, which produces a yellow-colored liquid). On adding a crystal of potassium dichromate to a solution of chrysarobin in sulphuric acid, the red color is changed at first to green, then to purple, and finally to brown.—U. S. When boiled with about 2000 parts of water (which produces only partial solution), the light reddish-brown filtrate does not affect litmus-paper, and is not altered by ferric chloride test-solution.—P. G.

The chrysarobin of the Br. P. should be completely soluble in hot chloroform, almost entirely in hot 90 per cent. alcohol, and partially in a solution of potassium hydroxide with the production of a deep reddish-brown color, and should not leave over 1 per cent. of ash when incinerated.

If 0.001 Gm. ($\frac{1}{64}$ grain) of chrysarobin be sprinkled upon a drop of fuming nitric acid, the red solution extended to a thin layer, and a little ammonia added by means of a glass rod, a violet color should be produced.—P. G. If sprinkled on concentrated sulphuric acid, chrysarobin should give a reddish-yellow solution.

Constituents.—Commercial Goa powder has contained from 2.65 to 75 per cent. of chrysarobin ($C_{30}H_{26}O_7$), with a small amount of chrysophanic acid, 0.8 to 66 per cent. of ash, and 14 to 32 per cent. of water. A good sample yields 60 to 75 per cent. of chrysarobin (70 to 85 per cent. of dried araroba), and not more than 20 per cent. of water and 3 per cent. of ash. The powder contains also 2 per cent. of resin, about 5.5 per cent. of woody fiber, and 7 per cent. of bitter extractive. Chrysarobin, purified by repeated crystallization from glacial acetic acid, occurs in small yellow scales, which are fusible and partly sublimable, nearly insoluble in water and ammonia, sparingly soluble in alcohol, more freely so in amyl alcohol, ether, collodion, chloroform, and various hydrocarbons. It is inodorous and tasteless. It dissolves in concentrated sulphuric acid with a yellow color, is nearly insoluble in very diluted potassium hydroxide solution, and yields with melted potassa a brown mass. (Chrysophanic acid dissolves in concentrated sulphuric acid and in very dilute potassium hydroxide solution with a red color, and yields a blue mass when fused with potassa.) Its solution in strong

potassium hydroxide solution has a yellow color and strong fluorescence, and on being agitated with atmospheric air rapidly acquires a red color.

Liebermann and Seidler (1878) established the identity of chrysarobin as a compound represented by the formula $C_{30}H_{26}O_7$, and that it is essentially different from chrysophanic acid, into which by absorption of oxygen it may be converted in alkaline solutions; thus $C_{30}H_{26}O_7$ (chrysarobin) + $2O_2$ yields $2C_{15}H_{10}O_4$ (chrysophanic acid) + $3H_2O$. Inversely, chrysarobin may result from chrysophanic acid $2(C_{15}H_{10}O_4) + 8H = C_{30}H_{26}O_7 + H_2O$. As prepared from araroba, chrysarobin is mixed with varying percentages of *methyl chrysarobin*. Boiled with glacial acetic acid, chrysarobin yields a number of acetyl derivatives. The *monacetyl* derivative forms yellow leaflets, which melt at 188°–190° C. (370.4°–374° F.); the solution in alcohol and acetic acid exhibiting a strong blue fluorescence. The *diacetyl* derivative forms yellow rhombic leaflets, which melt at 216° C. (420.8° F.), and the *β-diacetyl chrysarobin* yellow needles melting at 265°–270° C. (509°–518° F.). *Eurobin*, the triacetyl, and *lenirobin*, the tetracetyl derivative of chrysarobin, are commercial substitutes for chrysarobin. When chrysarobin is distilled with zinc-dust it yields *methyl anthracene*, $C_{14}CH_3H_9$. The researches of Liebermann have shown chrysarobin to be a reduced quinone.

Pharmaceutical Preparation.—Chrysarobin Ointment, U. S. P.

Action and Uses.—Chrysarobin is seldom employed internally, but it may be given in psoriasis in doses of $\frac{1}{8}$ grain (0.008 Gm.). If larger quantities are administered, it acts as a gastro-intestinal irritant, increases the flow of bile, and produces copious watery stools, and nausea and vomiting. The urine of persons using chrysarobin turns red on the addition of alkalies, and slight albuminuria is sometimes present when it is taken.

The local application of chrysarobin is not uncommon, and it has met with some success in the treatment of psoriasis and other chronic affections of the skin. Great care should be exercised in its employment, however, as it may cause pain, swelling, and inflammation in the tissue. If the cuticle is broken, sufficient of the drug may be absorbed to produce nausea and vomiting. It is commonly employed in the form of an ointment containing 10 grains (0.60 Gm.) of the drug to 1 ounce (30 Gm.) of ointment or benzoinated lard; but a weak solution made with water, vinegar, or chloroform is sometimes painted over the affected area, and when dry covered with collodion.

Chrysarobin has been employed in the form of a suppository, containing 1 grain (0.06 Gm.), in the treatment of hemorrhoids.

Chrysarobin leaves a dark-brown stain upon the skin, which may be removed by washing the part with a weak solution of chlorinated lime. Clothing with which it comes in contact is permanently discolored.

Allied Compounds.—Anthrarobinum, Anthrarobin, Dioxyanthranol, Leukoalizarin, Desoxyalizarin. $C_{14}H_{10}O_3$. Molecular weight, 224.38.—Anthrarobin is prepared from *alizarin* by dissolving the latter in warm ammonia water, adding zinc dust to the solution and heating the mixture until the blue color is changed to yellow; the solution is filtered into water strongly acidulated with hydrochloric acid, and the precipitate formed is washed by decantation until free from acid, and then dried on porous tiles at 100° C. (212° F.). The reaction is based on the reducing action of hydrogen, $C_{14}H_8O_4$ (alizarin) + $4H = C_{14}H_{10}O_3$ (anthrarobin) + H_2O. Commercial anthrarobin occurs in the form of an odorless, tasteless, yellowish-white powder. It is difficultly soluble in water, dilute acids, benzene, chloroform, and ether, somewhat more soluble in hot water, soluble in glycerin, fats and oils, in 5 parts of hot alcohol, and readily soluble in aqueous solutions of alkali hydroxides to brownish-yellow solutions, which on contact with air rapidly absorb oxygen and turn green, blue, and finally violet-colored, alizarin being again formed. The aqueous solution yields a reddish-brown precipitate with lead acetate solution and a brownish-violet precipitate with a solution of ferric chloride. On incineration, anthrarobin should not yield more than 0.3 per cent. of ash, and 0.1 Gm. should dissolve in 1 Cc. of sodium hydroxide solution and assume a violet color when air is forced through the solution. Anthrarobin is used like chrysarobin in the treatment of skin diseases.

Hydroxylaminæ Hydrochloridum, Oxyammonium Hydrochloricum.—*Hydroxylamine hydrochloride*, E.; *Salzsaures Hydroxylamin*, G. NH_2OHHCl. Molecular weight, 69.99.—The base, hydroxylamine, NH_2OH, which may be looked upon as ammonia in which an atom of hydrogen has been replaced by the hydroxyl group, is only known in its free state in the form of solution. By a rather complicated process hydroxylamine sulphate is obtained by the interaction of sodium nitrite and acid sodium sulphite. The hydrochloride,

which is obtained from the sulphate by treatment with barium chloride, occurs as colorless hygroscopic crystals, soluble in an equal weight of water, also in glycerin and in 15 parts of alcohol. It possesses strong reducing properties, precipitating metallic gold, silver, and mercury from solutions of their salts; it also reduces Fehling's Solution in the cold. From ammonium chloride, which it resembles in appearance, hydroxylamine hydrochloride is distinguished by its alcoholic solution not giving a precipitate with platinum chloride.

Tests.—Its aqueous solution (1 in 10) reddens blue litmus-paper, but does not react acid to congo test-paper (filter-paper saturated with a solution of 1 Gm. of congo-red in 1 liter of water and dried). The solution should not react for iron when tested with test-solution of potassium sulphocyanide and potassium ferricyanide, nor give a turbidity with dilute sulphuric acid (barium). 1 Gm. should dissolve clear in 20 Gm. of absolute alcohol. The salt should be kept in well-closed bottles. On account of its non-staining properties, hydroxylamine hydrochloride has been suggested as a substitute for other reducing bodies, chrysarobin, pyrogallol, and anthrarobin, in the treatment of skin diseases; but by some authorities it is pronounced dangerous if absorbed, being a powerful blood-poison and generally destructive to vegetable and animal life. It is used commercially as a developer in photography.

CIMICIFUGA, *U. S.*—Cimicifuga.

Cimicifugæ rhizoma, Actææ racemosæ radix, Br.—*Black snakeroot, Black cohosh, Bugwort, Rattletop*, E.; *Schwarze Schlangenwurzel*, G.; *Racine d'actée à grappes*, Fr.

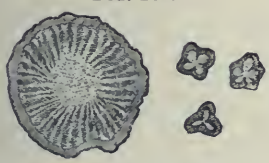
The dried rhizome and roots of *Cimicifuga racemosa* (L.) Nutt. (*Actæa r.* L.; *C. serpentaria* Pursh; *Macrotys actæoides* Raf.—Fam. *Ranunculaceæ*).

Origin.—A very handsome perennial herb of eastern and central North America, growing in rich woodland soil, especially among rocks. The slender stem is 1.8 to 2.4 M. (6 to 8 Ft.) high, is leafless below and above, and bears near the middle several large, petiolate, thrice-ternate leaves, with ovate-oblong, acute, and deeply toothed leaflets. The white flowers are in terminal branched racemes 20 to 30 Cm. (8 to 12 In.) long, have small, clawed, 2-horned petals, numerous stamens on slender filaments, and usually 1 pistil, producing a dry capsular fruit containing many flat seeds. It flowers in June and July and ripens its fruit in September, after which time the rhizome should be collected.

Fig. 107.

Cimicifuga (½ Nat.).

Fig. 106.



Cimicifuga racemosa: transverse section through a branch of the rhizome and through roots.

Description.—From 6 to 15 Cm. (2 to 6 In.) long and 1.5 to 2.5 Cm. (½ to 1 In.) thick, horizontal, with numerous crowded, short, thick, erect or ascending branches which are about 2.5 Cm. (1 In.) long, and half or more as thick as the rhizome, each terminating in a deeply cup-shaped scar; roots coarse, brittle, obtuse, quadrangular, about 2 Mm. ($\frac{1}{12}$ In.) thick; odor slight, heavy; taste bitter and acrid; fracture smooth, the rhizome exhibiting a rather large pith, surrounded by numerous sublinear whitish wood-rays and a thin firm bark, the roots with a thick bark and a 3- to 5- (mostly 4-) rayed wood.

The starch-grains are either simple or compound, the simple ones mostly less than 10 mikrons broad, round or oval, with a nearly central hilum, the rings wanting or faint.

Both black and green hellebore bear considerable resemblance to cimicifuga, but can be distinguished by the small number and greater breadth of the wood-bundles of the rhizome, and the nearly cylindrical wood-zone of the roots (see Helleborus).

Constituents.—Cimicifuga contains gum, starch, 2 resins, fat, wax, cane-sugar, an uncrystallizable sugar, a crystalline neutral body, and a resinous amorphous body, probably the active principle. Trimble found no tannin, though other analysts mention both tannic and gallic acids.

The seeds yield the same constituents.

Pharmaceutical Preparations.—Extract of Cimicifuga, U. S. P.; Fluidextract of Cimicifuga, U. S. P.; Compound Syrup of Cimicifuga, N. F.; Tincture of Cimicifuga, U. S. P.

Action and Uses.—Full doses of cimicifuga when given to the lower animals paralyze the sensory side of the cord. In man it depresses the sensory side of the cord and depresses reflex action. Its effect upon the circulation is that of a depressant both to the heart muscle and the vasomotor center; the pulse becoming somewhat slower and blood-pressure decreased. Very small doses are said to act as a cardiac stimulant. Lethal doses cause death by respiratory paralysis. Full doses occasion violent frontal headache, dimness of vision, and at times nausea and vomiting. Overdoses produce headache, vertigo, tremors, and great depression. The employment of this drug is entirely empirical, as its known physiological action bears no relation to its use as a remedy. Cimicifuga is a uterine tonic producing normal contractions, and may be employed during labor when uterine inertia exists. If given during pregnancy it may produce abortion. It has also been highly recommended in the treatment of ovarian neuralgia, uterine tenderness, subinvolution, and amenorrhœa. By some it has been given as a substitute for digitalis in the treatment of fatty or irritable heart, but is rarely employed except as a last resort after other remedies have failed. Black cohosh is, after arsenic, the best drug for the treatment of chorea, especially if rheumatic tendency exists. This remedy has also been recommended in the treatment of headache due to eye-strain.

The dose of the extract is from 1 to 5 grains (0.06–0.30 Gm.); of the fluidextract, from 10 to 30 minims (0.60–2 Cc.); of the tincture, from 1 to 2 fluidrachms (4–8 Cc.).

Allied Drugs.—The rhizomes and roots of several species of the closely related genus *Actæa* L. (*Baneberry*) are quite similar in appearance, composition, and properties to *Cimicifuga*. That of *A. spicata* L., the *European baneberry*, *Herb Christopher*, *Christopherwurz*, *Racine de St. Christophe*, or *Wolfwurz*, has been most used. This drug is smaller than *Cimicifuga*, as well as darker and less tough and woody, and with less prominent stem-scars, otherwise closely resembling it. The *West American red baneberry*, *Red cohosh*, or *Coral and pearls*, is *A. arguta* Nutt., the East-American being *A. rubra* (Ait.) Willd. (*A. spicata rubra* Ait.). The *White baneberry* or *White cohosh* is *A. alba* (L.) Mill. (*A. spicata alba* L.). The rhizomes of all closely resemble that of *A. spicata*.

CINCHONA.

Peruvian bark, E.; *Chinarinde*, G.; *Quinquina*, Fr.; *China*, It.; *Quina*, Sp., Port.

The dried bark of several species of *Cinchona* L. (Fam. *Rubiaceæ*).

Official Kinds.—1. Cinchona, U. S.—*Cinchona flava*, U. S. 1880; *Cinchonæ flavæ cortex; Cortex chinæ calisayæ; Cortex chinæ regiæ; China regia.*—*Yellow cinchona*, *Calisaya bark*, E.; *Calisayarinde*, *Königschina*, G.; *Quinquina calisaya*, *Quinquina jaune royal*, Fr.; *China gialla*, It.; *Quina Calisaya*, *Quina Amarilla Real*, Sp.; *Quina Amarella*, Port.

The dried bark of *Cinchona Ledgeriana* Moens, *Cinchona Calisaya* Weddell, *Cinchona officinalis* L., and of hybrids of these with other species of Cinchona (Fam. *Rubiaceæ*), yielding, when assayed by the U. S. P. process, not less than 5 per cent. of anhydrous cinchona alkaloids, of which at least four-fifths should be soluble in ether.

2. Cinchona Rubra, U. S.—*Cinchonæ Rubræ Cortex*, Br.; *Cortex Chinæ*, P. G.; *Cortex chinæ ruber*, *China rubra.*—*Red cinchona*, *Red Peruvian bark*, *Red bark*, E.; *Rothe Chinarinde*, G.; *Quinquina rouge*, Fr.; *China rossa*, It.; *Quina roja*, Sp.; *Quina Vermelha*, *Quina de Chimborazo*, Port.

The dried bark of *Cinchona succirubra* Pavon (Fam. *Rubiaceæ*), yielding, when assayed by the U. S. P. process, not less than 5 per cent. of anhydrous cinchona alkaloids.

In framing the first of the above definitions, the Pharmacopœia seeks the two objects of qualifying as to kind of bark included, namely, that in which quinine is the important alkaloid, and the strength or percentage of alkaloid to be contained. At the present time, we know only the two first-named species and a probable hybrid of one or the other of them with the third-named, which can answer to these requirements. *C. officinalis* itself answers the first requirement but not the second. Yet it is well known that

there are other species of the quinine-group which may at any time exhibit satisfactory hybrids, hence the provision as to "other species." In framing the second definition, the object is merely to secure a sufficient percentage of bitter alkaloid for tonic purposes, without regard to the ratio of quinine.

Cinchona is official in all pharmacopœias and both the above barks in most of them, but the definitions and specifications, as to species, gross and microscopical appearance, reactions, and assays, are too varied for full discussion in this article. The B. P. entirely omits the quinine barks, depending upon the quinine itself, but makes red bark from cultivated plants official, requiring that it yield between 5 and 6 per cent. of alkaloid, not less than half of it quinine and cinchonidine. This is in accordance with the British medical view, that these two alkaloids are of equivalent medicinal value.

Origin.—*C. Calisaya* is a large and beautiful forest-tree of northern Bolivia and southern Peru, and is one of the most extensively cultivated kinds. Excessive collection previous to the era of cultivation so nearly exterminated it that its reappearance in the native forests, since its cultivation almost stopped its collection there, has been very slow and inconsiderable.

C. Ledgeriana is a very similar and closely related species to the last, and is by many regarded as a mere variety of it. It was discovered, its superior quality recognized, and its cultivation urged and secured by a faithful native collector in the employ of Mr. Ledger, to whom the latter noble-minded gentleman always accorded full credit. It is from the same region as *C. Calisaya*, but has always been scarce and local, and it is only through cultivation that any adequate supply has become available. It is probably the most extensively cultivated kind, and is steadily replacing the others, because of its greater richness in quinine, absolutely, though the ratio of this to other alkaloids is about the same as in *C. Calisaya*.

C. succirubra is a large tree which originated upon the high slopes of Mt. Chimborazo, and which has been cultivated upon a very extensive scale. Owing to its present recognized inferiority to the quinine barks, and to its lower price, its cultivation has been largely abandoned.

C. officinalis, though very important, is not itself official, and must be considered under *Unofficial Barks*. Though named in the definition, it has never yet yielded the required percentage of total alkaloid.

Our present supply of the wild barks is, as stated, entirely unimportant. Cultivated commercial supplies come chiefly from Java, though there are extensive plantations in India which also supply commercial bark, besides much more extensive ones worked to supply the needs of the British Government. Some rather extensive plantations exist in Bolivia, but transportation across the Andes handicaps their success. Ceylon formerly produced a very large quantity, but the substitution of tea-planting, and a disease very fatal to the cinchona trees, have pretty nearly eliminated this source of supply. The Straits Settlements produce a moderate quantity. In Africa, Jamaica, Brazil, Mexico, the Fijis, and some other countries, unsuccessful attempts to establish plantations have been made. The United States is without any locality in which cinchona could be produced, though this is doubtless possible in some of its newly acquired tropical territory.

The trees thrive upon well-drained mountain slopes, with an equable temperature, abundant rainfall, and humid climate. In 18° south, an altitude of 4500 to 5500 feet is found most congenial. Although the calisaya of the native forests used to attain a trunk diameter of 2 or 3 feet, it is found economical in cultivation to collect the bark as soon as it is "ripe," that is, containing its normal alkaloidal percentage, a condition determined, in Calisaya and Ledgeriana barks, by the "chicken-leg" appearance of the bark, due to its profuse reticulation of intersecting fissures (see *Description*). This occurs at about 6 to 9 years of age, the trunk being then about 6 or 8 inches in diameter. The trunk-bark is removed and dried in quills. For pharmaceutical purposes, it is mostly marketed in this condition, and is known as *Druggists' bark*. Some very handsome bark of this form comes from the South American plantations. For manufacturing purposes, the quills are broken up and pressed, to save transportation charges. *Manufacturers' bark* is purchased entirely upon its assay, at a price per unit, the unit being each 1 per cent. of quinine in a pound of bark. To this class of barks belongs also the root-bark, which is richer

than the stem-bark. The bark of the branches is very inferior, as to both yield and appearance, and is found difficult of sale, the cost of manufacture being excessive in proportion to the weight of alkaloid recovered. Such young bark is very thin, and becomes much wrinkled in drying (Fig. 109). Owing to an increase in the production of alkaloid, with a corresponding decrease in that of coloring-matter, when light is
